Disclaimer

The material in this book is prepared in good faith and carefully reviewed and edited. All care has been taken to give the latest position of law and to explain it from academic and application point of view. Safety measures suggested are mostly based on Indian Law, Indian Standards, self-experience and some International Standards, self-experience and some International Standards. However they should be applied after careful consideration of one's need, situation, environment, special circumstances and alteration, modification, addition or subtraction necessary as per standard engineering practice, safe control technology, good principles of safety philosophy, psychology, management and medical science. In no way the author, publisher or printer are responsible for any unknown error, omission or act in good faith in publishing this book.

Price Rs. 1200/-

Foreword

The first edition of this book was published in June 1987. Sine then the syllabus of the Diploma Course in Industrial Safety has undergone Safety has undergone revision. Also, the Course has been re-designated in Maharashtra as Advanced Diploma in Industrial Safety from the academic year 1997-98. There is also a move to increase the duration of the Course to one and half years. If it materializes, the contents of the revised syllabus may further undergo some additions.

Furthermore, the last decide has witnessed a number of new safety related legislation being placed on the statue book. These legislation include 'Manufacture, Storage and Import of Hazardous Chemicals Rules, 1989' as amended in 1994; 'Hazardous Waste (Management & Handling) Rules, 1989; Public Liability Insurance Act 1991; National Environment Tribunal Act, 1995; Chemical Accidents (Emergency Planning, Preparedness and Response) Rules, 1996'; Bio-Medical Waste (Management & Handling) Rules, 1998 and 'Central Motor Vehicle Rules, 1989' as amended in 1993 regarding road transportation of dangerous goods.

IS : 14489- 1998 as Code of Practice on Occupational Safety & Health Audit has provided good guidelines and uniformity in the subject of Safety Audit, again a statutory requirement.

The revised edition of the book is therefore overdue. The second edition of this book has taken care of the changes which have taken place in the syllabus and the statutes mentioned above and also updated the other data.

The book serves to provide in one volume the basic reading material required for pursuing the studies of the Diploma Course and should be found very convenient and useful by the students and faculty members alike without having to hunt for different sources of information. However, it does not mean that other references on specialised topics would not be required.

The author, Shri U.K. Mistry, is personally known to me for a number of years. Despite being a Senior Inspector of Factories with the Government of Gujarat, he is not depending upon the use of his statutory authority for achieving improvement in occupational safety and health conditions in factories. He is sincerely committed to improvement of knowledge and professional standards and promote a regime of self-compliance by management. I whole heartedly welcome this valuable contribution by Shri Mistry to the professional world. This book is a laudable effort to achieve this objective. I wish the book and its readers a great success.

K.C. Gupta
Director General
National Safety Council of India
Mumbai.

This book is dedicated to :

1. *All our genius forefathers and safety philosophers who have tried to save the mankind since centuries.*
2. *All scientists, engineers and authors who have contributed safety techniques, rules, regulations, standards, equipments and safety devices.*
3. *All legislators, judges, officials, unions, associations, employers, employees and professional who made safety laws, interpreted and implemented for the safety, health and welfare of all people.*
4. *All who have been and who are propagating for the cause of Safety and Health.*
5. *All who are prepared to work for Safety, Health and Environmental protection.*

Pre-conditions of Acquiring knowledge.

An engineer should be fully qualified and capable of doing all types of construction work. None of his body parts should be defective or excessively short or long. He should be practitioner of 'Dhar', benevolent, unmistaken, active, mechanic, healthy, tolerant toward others' progress, mathematician, historian, truthfully and self controlling. He should be well conversant with drawing, design, time, weather and meteorology. He should be free from disease, laziness and seven evils of greediness, intoxication, gambling etc.

Preface

After the publication of the first edition of this book in 1987, twenty years have been passed. The book was welcomed and highly appreciated by all safety students, readers and professional people in industries who gave their feedback. An esteemed response was received from throughout the country by letters (still continuing) and personal inquires by the lovers of the book. This gives satisfaction and encouragement of the work done generously and sincerely. The main intent of writing this book Is to save life, environment, loss to men and materials and to prevent, control and mitigate hazards and accidents by creating safety awareness and preparing safety officers for this noble cause. Protection of human being is kept at the centre-point of the writing.

It is good that health and safety movement is taking momentum in this country, safety awareness at all levels is increasing, new statutes on safety law have come up during last twenty years and need of safety education and training is gaining more and more importance. It is made statutory in factories and the concept of Safety Officer, Factory Medical Officer and Industrial Hygienist and their work is recognized. The age-old factories Act, as it stands updated by its last amendment in 1987, and other safety statutes mentioned in this book, are the backbone of the whole safety law and requirements in our factories. In this perspective, the need of Safety Course and the need of such books are always justified.

The syllabus for the course of Post Diploma in Industrial Safety, as prepared by DGFASLI, Mumbai and approved by AICTE, New Delhi, in 1996, has been accepted by most of the State Governments including Gujarat. The Technical Examinations Board (TEB), Gujarat implemented this revised syllabus (curriculum) from the academic year of 1996-97. The Curriculum Development Centre (CDC), Ahmedabad revised and updated this curriculum in 2003 and TEB implemented it. This second edition of this book is entirely revised, renamed, enlarged and effort is made to prepare this handbook on this revised syllabus. It will certainly be useful to all the students and safety people in all the States. Chapters 7, 27, 28 and 29 are most useful to any person desiring to establish an industry in India as far as the statutory provisions are concerned though they are also subject wise given in most of the Chapters.

I have also gone through the syllabus of a new course – Master of Industrial Hygiene and Safety (MIHS), started from 3-9-1997, first time in India, at BVM Engineering College (now at ISTAR), Vallabh Vidhyanagar, Anand, Gujarat and some subjects of this course are also incorporated in this book.

This new edition includes following features :

1. The chapters have been rearranged.
2. Ample new material is added in all the chapters.
3. All new topics inserted by the revision of syllabus have been incorporated.
4. Figures, drawings and pictures have been added which were missing in the first edition.
5. An ‘Exercise’ is added at the end of each chapter. This is useful to PDIS and MIHS students for preparation of examinations.
6. Names of more reference books have been added at the end of each chapter.
7. Main ‘Index’ is expanded to find more headings quickly and new ‘Subject Index’ added at the end.
8. ‘Theme’ of the topics is maintained in the beginning of each chapter. It helps is grasping the whole chapter at a glance and to remember the contents.
9. Building of details is possible only when the foundation of fundamentals is sound. Therefore emphasis is given to clarify the fundamentals, concepts, definitions, principles, Indian Standards, Indian Law and essential requirements, rather than to increase a burden of more details. Looking to the inclusion of B.Sc. and Diploma students, this approach seems to be more useful. Aim of the

writing is maintained to prepare safety officials and professionals and not only the students. The book is equally useful to Inspectors of Factories or Directors of Industrial Safety and Health.

10. Presentation is kept plain, simple, lucid, exhaustive and easy to understand by the readers. The content depth is varying and limited by the size of the book.

While preparing this revised new edition, hundreds of books, standards and specifications have been referred. I have utilized my class-notes, lectures, reports, remarks, publications and materials from many known and unknown sources. Many books not referred but useful to students are also included at the end of each chapter. Abstract of experience of more than 35 years, has blended all such materials on the centerline of the prescribed course to deliver an intended product. Being busy with other works, it required some ten years for planning, thinking, continuous writing, rewriting and finalizing of this new edition.

To explain the target area of safety work, ample statistics is given in Chapter 5 and in other chapters with relevant topics, for which the sources of Labour Bureaus, Shimla, Office of the CIF, Ahmedabad, NSC (USA) publication – Accident Facts, 1997, Loss Prevention News, Some Indian companies and news reports are gratefully acknowledged.

Hazard control technology has expanded much and will continue to expand. New plants are coming with built-in safety feature but owing to their complexity and automation, a job of a safety officer is becoming more tough to understand and identify the hidden hazards and to suggest their remedial measures. The complex plants may be vulnerable but the application of accident prevention philosophy, techniques and safe operating procedures envisaged in this book will go a long way in preventing accidents.

However the fact remains the same in developing and under-developed countries that safety status in more than 90% small and medium scale factories is still poor, below standard and needs much effort of safety officers to improve it. Thus, despite of the latest hazard control measures in a very few companies, the vast area is still open to work hard for safety and health problems in majority of the factories. About 3 million small scale industries are located in India. This book will certainly help to all such industries in this regard to understand the subjects of safety from fundamentals to the as-on-today status and to select and apply hundreds of remedies to our present problems. Systematic basic approach leading to the details, step by step, reinforced with the statutory provisions, Indian Standards and accident case studies will mould our safety professionals to help the industries to fulfill their legal requirements.

I cannot conclude without thanking my colleagues, who helped me directly and indirectly, Shri Sharadbhai Shah, Shri Partha Sengupta and Shri Kishor Kanzariya who computerized a voluminous manuscript, Shri D.H. Patel, Charted Engineer, Safety Professional and a Competent Person, Shri HS. Dave, Deputy Director of Industrial Safety and Health Consultant and General Surgeon, Dr. Jagdashbhai D. Shah, Occupational Health Consultant, Shri Amit D. Parikh, Lecturer at MIHS and Shri S.H. Munshi, Lecturer for providing various standards, specifications, examples and photographs and discussing many safety matters.

I am also thankful to many manufacturers and suppliers of personal protective equipments whose published photographs and figures have been utilized in this book.

How can I forget to express my deep gratitude to Shri K.C. Gupta, Director General of National Safety Council, India for writing Foreword and increasing the beauty of this book.

Nothing could have been possible without the tolerance and sacrifice of my family members as I could not spare sufficient time for them. Words are insufficient to express my debt of obligation towards them.

At the end, I would like to say that this is not the end, because, the process of acquiring and spreading knowledge has no end and it is the best habit as per our Indian philosophy.

O;lukfu lfUr cgq'k%] O;lu};eso dsoy O;lue~ A
fo/;lH;lua O;lua ;n~ ok gfjiknlsoua O;lue~ AA

Habits are many but only two are important: a habit of learning and a habit of serving the lotus feet of the God. This is the only conclusion.

Ahmedabad

CHAPTER – 1

The Concept of Safety

THEME

The first requirement before going through any book on Industrial Safety is to properly understand the Concept of Safety.

The concept of safety can well be conceived by understanding the struggle of Dead Vs. Live resources, Health Vs. Wealth and Industrialization Vs. Accidents.

1. DEAD Vs. LIVE RESOURCES

All-resources in this world can be classified in two parts only-Dead and Live Resources. All elements, compounds, minerals, metals, non-metals and all material things that are not alive, are called Dead Resources. All living creature including human being are live Resources. All dead resources are invented, produced and used by the live resources. If there is no live resources, there is no important of any dead resource. However, haphazard generation and use of dead resources have created a great threat to the live resources and therefore a question of safety has been arisen.

Now, a question arises – Out of dead and live resource, which is more important? Out of man and machine who is more important, machine or its creator a man? All raw materials to be processed in industries are dead raw materials with few exceptions like killing of animal or generation of live culture for fermentation etc. But most of the raw materials like metal, non-metal, important to run the industry for producing goods and services needed for the mankind. But can they alone run the industries? And after all they are for whom? They are produced and processed for whom? And by whom? The simple reply brings before us a man-the live and real resources for the world, industry and any activity. It is the man behind machine who operators it and who has made that machine and who also repairs and maintains. it is the human being only who has invented the dead raw material, their uses, machines processes products and utility for various purposes. If he is absent, the dead raw material are of no use. Therefore it is obviously inferred that the live resources, the human beings, are more important than the dead resources. Therefore we must pay more attention on these live resources. That is why the Safety, Health and Welfare of people are considered to be of prime importance and we must never forget them. The dead raw materials are not for the destruction of mankind. The wise people always oppose such misuse. The contact of man and machine, man and material, man and environment must be safe.

We are also worried that hazards are being shipped overseas. Dangerous raw materials and discarded plants of developed countries-because safety and health conditions are laxer here? These dangerous dead resources are causing threats to the live resources that have to run these plants.

Now days the importance of human resource is increasing worldwide. That is why we found Human Resource (HR) Department in industries. The basic object of HRD is to pay more attention and refine human resources. These human or live resources can be developed (refined) only when they are protected from the dangers of dead resources. This protection is nothing but the Concept of Safety.

2. HEALTH Vs WEALTH

The most important live resource is a man. If we concentrate on this 'man' what is more important? His Health or Wealth? The simple reply is both', because men want both. But the well-known maxims like health is wealth, sound mind in a sound body, 'kjhjek|e~ [kyq /keZlk/kue~] point out that the health is more important Yet it seems that the people take more care of wealth than the health. Many lose their health and life in a race for the wealth. The growing industrialization is also a race for the wealth. It has brought many hazards and threats to its creator a **man** himself? Health of people is day by day worsening and it seems that the wealth is constantly challenging the health.

The great philosopher E.E. Schumacher explains, 'In the excitement over unfolding of his scientific and technical power, modern man has built a system of production that ravishes nature and type a system of production that ravishes nature and type of society that mutilates man. The development of production and the acquisition of wealth have become the highest goals of the modern world in relation to which all other goals have come to take second place.

The mad concept of wealth and growth is explained by Jay Forrester in the following words:

If the developed countries continue to increase their demand for material goods as hither to, life on earth may come to a horrible end around 2070, owing to either massive starvation or fatal levels of pollution, for the affluent countries are spending themselves to destruction in a mad pursuit of growth that has ceased to have any meaning for them.

In an Agenda of Science for Environment and Development into 21st Century, Maurice F. Strong, Secretary General, UNCED writes – "Mankind is in the process of over whelming nature. And there is a penalty we must all pay for our domination of the natural world upon which we have always depended absolutely…. We are forced more and more to take up the burden of being responsible for its survival forever…. Instead of being a minor guest at the Earth's table. The human species is on the way to consuming the whole feast and we are in danger of being forced into a partnership with nature to provide the feast forever. We must not turn the gift of nature into a Faustian bargain."

Justice K. Ramsawami of our Supreme Court, begah his landmark judgement (1995) on asbestosis with the following words;

"Occupational accidents and disease remain the most appalling human tragedy of modern industry and one of its most serious forms of economic waste"

World Environment (1985), a a brochure published by Lok sabha Secretariat, New Delhi, in 1985, throws much light on environmental problems. Its introductory opening paragraph runs as under.

"Over the course of ten thousand years humans have successfully learned to exploit ecological system for substance. While ecological system are supple, they can snap viciously when bent too far. The land's ability to serve human ends can be markedly and sometimes permanently snapped. Humans out of ignorance, short-sightedness, greed or desperation have polluted air and water, undermined the productivity of the land through accelerated soil erosion, creeping deserts, increased flooding and declined soil fertility. They thus destroy the basis of their own livelihood and they violate the limits of natural systems. The principal victims of these trends are the world's poor, who, in their quest for food and fuel, are often, forced by circumstances beyond their control to serve as the agents of their own undoing".

Worldwide environmental issues mentioned in this brochure are :

1. Climatic Changes.
2. Risks to Ozone Layer.
3. Acid Rain.
4. Pollution of World's Oceans.
5. Desertification.
6. Loss of Tropical Forests.
7. Soil Loss, and
8. Depletion of Genetic Resources.

The present status on these issues in India is dissatisfactory as evident from the following report.

The State of India's Environment 1984-85, i.e. the Second Citizen's Report published by the Centre for Science & Environment, New Delhi, describes how our land, water, forests, dams atmosphere, habitat, people, health, energy and living resources are deteriorated and what the overall effects on our national environment are. It says due to 50 – fold increase of mineral production in last 30 years, several million hectares of good crop and forest lands have been destroyed by mining operations and hundreds of villages depopulated. The satellite data confirms that India is losing 1.3 million hectare of forests a year, nearly 8 times the annual rate put out by the forest department. India uses @ 1 lakh ton of pesticides annually of which 70% is banned by western countries. A WHO study, which anlaysed food samples across India, found that 50% were contaminated with pesticide residues and 30% exceeding permissible limits.

Thousands of workers die every year due to occupational diseases (most of which remain unreported), the gravest being caused by various types of dust from slate pencil factories, mines, thermal power stations, fertiliser and pesticide factories, textile and sugar mills, asbestos, tobacco & wood factories and thousands of toxic chemicals from variety of chemical factories.

'Down to Earth' report of 15-10-1996 prepared by Carten Brendon and Carston Homen of the World Bank says that every year Indian suffers a loss of Rs. 34000 crores due to loss of environment which results from the process of industrial growth ! It clearly speaks that in 23 major cities of India, the air pollution is much higher than the maximum permissible level, and suspended solids in four major cities are 3 to 4 times more than WHO standards. CO, SO_2, NO_x and Hydrocarbons are killing thousands of people every year. Some 3 crores man-days are lost every year due to the effect of polluted water. The ground water level is dangerously decreasing. Some 40 lakhs people get affected due to air pollution in Delhi alone. Serious diseases are constantly increasing and the health of people is really in danger due to such chemical effects.

'Green –peace International report' published in 'The Times of India' on 10-12-1996 says that some three million small units throughout India contribute about 45% of industrial pollution. It said that @ 50% of the chemical storage tanks were found in bad condition with over 61% units having no scheduled maintenance system for storage tanks. Almost 80% workers were not using personal protective equipment. Alarm systems were visible in 18% units and written procedures were found in 17% unit only. There was a shortage of qualified, managerial and supervisory staff in 45% units surveyed. The Green-peace warned about continuing use of mercury cell method (instead of membrane cell technology made compulsory since 1986) in Chlor-alkai industries. Mercury is highly poisonous to human nervous system. It also spelled out dangers of exposure to Organochlorines, which might lead to fatal deaths and spontaneous abortions and cancer to industrial workers. A number of synthetic chemicals including Organochlorines, Organophosphorous etc. every in the tiniest amount could lead to fall in fertility and changes in sexuality in males and females, it added.

Atlanta Report published in Atlanta Journal on 18-11-1992, gives warning with the signatures of 1175 Scientists (of which 100 are Noble Prize Winners), as under.

Due to the dangerous effects of environmental pollution, more than 20% trees and plantation, animals and other living creature will die in near future. If no remedial measure will be taken, ice-mountains at North Pole will melt due to green house effect, tide will come in number of seas, more and more cities and villages will float in sea waters, lakhs of acres land will sink in water and food grains and other commodities will be carried away by the tide waters, this warning will prove true before the year 2010, the scientists added.

Glowing Girls ! – An oldest report says that in Switzerland girls were doing the jobs of painting radium on clock dials. While doing so, unknowingly, they were just holding, the radium needle between their lips. After a long time it was observed that their eyes were actually glowing during night as radium dial glows. They were looking fine because of their shining eyes and they were preferred for marriages. Unfortunately, they began to die prematurely at an early age. As a result, the use of radium was prohibited to paint clock and watch dials.

Report of Indian People's Tribunal submitted to the Government of Gujarat and GPCB is published. It discloses a study of 25 villages near 56 km long canal carrying polluted water from Vadodara to Khambhat. It indicates the increased level of metal deposition on food-grains (crops in lakhs of hectares of land in these villages. Reported metal levels in food grains are given in **Table1.1**.

Table 1.1. : Metal Level in Food grains

Food-Grain	Metal	Normal level (mg)	Increases level (mg)
Wheat (1 Kg.)	Hg	1.10	2.40
	Fe	6.70	41.30
	Cd	2.40	21.30
	Ni	1.0	2.10
	Zn	99.4	367.4
	Cr	1.10	3.40
	Cu	76.30	89.80
	Ca	5111	6017
Pigeon Peas (bean) (Tuver Dal) (1 Kg.)	Pb	1.20	4.20
	Ni	1.30	61.50
	Zn	9.90	38.20
	Cr	1.30	8.80
	Cu	1.10	2.60
	Fe	4.80	26.60
Maize (Makai) (1 Kg)	Cu	1.90	16.30
	Cr	1.10	3.90
	Zn	108.70	318.10
	Ni	2.10	63.40
	Pb	1.30	3.30
	Cd	2.10	8.90
	Fe	8.20	21.70
Bajara (1 Kg)	Cu	136.20	204
	Cr	2.0	63.20
	Zn	262.80	427.20
	Ni	1.10	3.20
	Pb	1.30	2.30
	Cd	2.20	10.70
	Fe	2.80	25.70

Such heavy metals enter the body through food and attack liver, kidney, intestine, bladder, brain and the blood circulation. This seems to be the main cause of increasing many disease including cancer (News 12-06-2000).

Such open canal should never be permitted Animals can drink such water. Polluted water must be discharged through a closed pipelines. Farmers should be advised not to use such wate.r penal actions should be taken against the sale of such food-grains.

It is reported that Mahi and Mini Rivers in Gujarat were severely polluted 30 years before due to 200 poisonous factories in Vadodara area. In 1969, Gujarat Government had constituted a committee to inquire into this matter. As a result 56 km pipeline was laid down between Vadodara and Khambhat. Reports of NEERI, Nagpur and MS University, Vadodara, both had told that the ground water in Bajava Village was not remained potable. The same is the case at many places near the chemical factories.

30 villages on riverbanks in Gujarat drink fluoride rich salty water and invite many diseases (News 26-12-02).

The water of Ganga river is highly polluted. 21 big cities near ganga throw 140 crore liters untreated sewage water daily into it. Thousands of factories throw poisonous chemicals into it. This causes 88% pollution of Ganga. Ganga Action Plan of Rs. 1000 crore has failed. Many dams on Ganga river has restricted its flow. As per CNN- IBN report, name of Ganga has been added in the highest polluted five big rivers of the world. (News 19-02-2008).

The water of Yamuna river is so polluted that it is of no use for any purpose. The Central Pollution Control Board has published this fact in their report (News 17-02-97).

Grampanchyats in Andhra Pradesh ordered the public to take bath at 4 days and to wash cloths at 10 days, otherwise there will be a fine Rs. 500 ! (News 3-02-03).

UNICEF published a report that if planning for proper preservation of water will not be made; people will fight for a drop of water in coming 20 years. (News 29-04-20002).

Vadodara, Bharuch, Surat and Vapi are named as most polluted areas where environment including water, air, fish, fruits and crops is badly damaged. The Golden Corridor has been blackened, it is added (News 31-10-2000).

"Stress and pollution render more men infertile" was the headline of the Times of India, Ahmedabad, of 6th June 2000. "Incidence of infertile males seeking In-Vitro Fertilization (IVF) the world over has risen up to 50%" it was reported. Modern lifestyle – over exposure t heat and pollution, stress, habit, tight clothing, unsafe sex, tobacco chewing and infections – shown as the main reasons. (News 06-06-2000).

Peoples Training & Research Centre and Vyavsayik Swasthya Suraksha Mandal, Vodadoar,a has published in April 1999, an appeal letter to celebrate '28th April as 'The World Workers Remembrance Day'. It quotes some WHO figures as under :

Worldwide 12 crores accidents occur every year wherein 2.20 lakhs workers die. Some 16 crores new cases of occupational diseases are being added every year ! 40 to 50% of the total workers of the world apprehended physical, chemical, biological, ergonomic or mental hazards due to work. About 1 lakh chemicals pose serious health hazards. Some 300 pollutants can cause cancer. Skin, bones, lungs and kidney are the main target organs. 3000 allergens can cause skin diseases (dermatitis), asthma etc. Economic loss due to occupational diseases is @ 10 to 15% of the total world GNP. 75% of these diseases are preventable, adds the World Bank. In developed countries 20 to 25% and in developing countries, only 5 to 10 workers get occupational health services.

Central Labour Secretary Dr. L. Mishra told on the eve of 36ht Indian Labour Conference that factory occupiers do not provide safe and comfortable atmosphere to the workers and ignore their physical and mental well being. He added that 40 crore tones of chemicals are being manufactured in the world and more and more are being added to it. Out of one lakh chemicals used in industry and agro sectors, health hazards of only three thousand chemicals are known. 250 chemicals are carcinogenic. Contact with some metals, organic dusts and pesticides is dangerous, he added, and warned about the toxic dusts in paper and pulp industry, petroleum refinery and ceramic industry, insufficient lighting and ventilation, exhaust system and inadequate machine design. He was referring the agenda report prepared by the Central Labour Ministry for the above conference (News 13-04-2000).

Dangerous radioactive Cobalt – 60 was detected on wrist watches of brand name 'trafy' and made by Silk time Company of Hongkong. Atomic Energy Regulatory Board, Bombay and office of the Protection against Ionising Radiation, France issued warning against the use of this material (News 11-11-2000).

It is reported that high selling Gutkha contains Magnesium carbonate and it is banned for sale at certain public places. American Cancer Society has highlighted the increase incidence rate of cancer (adenocarcenoma) due to smoking of filtered cigarettes (News 7-11-97).

European Union announced prohibition on the products from animal organisms causing **mad cow disease** (News 7-11-97).

Germany has banned the import of Indian textiles containing **azo dyes** made from chemicals that it suspects are carcinogenic.

TV News are constantly warning about the continuously decreasing levels of water in land and simultaneously continuously increasing population and their massive demands. Coal, natural gas and petroleum are also constantly decreasing. Can it not pose a great danger to our lives after 50 years ?

Petroleum Minister Shri V.K. Ramamurty told in Rajyasabha that our Crude – oil stock would last for 27 years only (News 19-3-99).

Is it not shocking news that in Cherapunji – a place known for the highest rainfall – the water is being sold in buckets ? Failure of water planning will add to the health hazards.

The Chairman of the World Commission for Water has warned about the grave misuse of land and water sources. Polluted rivers spoil the eco systems and therefore the health and subsistence of people depending on irrigation, drinking water and industrial use of water have been seriously endangered (News 30-11-1999).

'In next two decades, 66^% population of the world may face difficulty of drinking water' said Kofi Aanan, the General Secretary of the UNO on the eve of 22-03-03 the World Water Day. He stressed on prevention of waste of water and told that the clean water is the most essential for human existence and continuous growth. (News 23-03-03).

Bhopal gas-tragedy of 2/3 December 1984, arose out of Methyl isocyanate leak, killed some 2500 people and left after-effects on thousands others. On 21-01-97 an Ammonia tanker leaked on Bhopal – Hoshangabad highway and caused some 400 people to be hospitalized and 30 acres land and crop badly affected. Reports of Ganga River pollution are also very bad. It has reported lethal effects due to Arsenic poisoning. Figures of pollution of Sabarmati river in Nov-Dec 1996 revealed that suspended solids were found 5134 to 56246 at four points against its permissible level of 100. In Delhi 70% air pollution is due to vehicles, which kill directly and indirectly some 7500 people every year ! (News, Editorial, 18-10-96).

Delhi, Calcutta and Bombay are included in the highest polluted 15 mega – cities of the world. Delhi is at No. 4 because of its highest level of suspended particulate matter (spm) in air. During 10 years from 1971 to 1981, industries increased from 20000 to 41000 in Delhi (News 4-3-97, the National Safety Day).

Reports of spoiling of the historical monument **Tajmahal** due to air pollution have also been published. Its whitening process was also started.

Fourth report of the Gujarat Legislative Assembly Committee speaks of the serious pollution problems due to the chemical industries in the state. Adverse effects have been noticed on agriculture, plantation, trees and the public health. The committee has urged the Government to take drastic steps to control this pollution. (News 9-3-97).

International Union for Conservation of Nature and Natural Resources, National Environmental engineering research Unit and National institute of Oceanography have warned about the dangers of gigantic oil refineries to Marine National Park (area 457 Km^2) and all living creature in a long sea coast of Saurasthra and massive pollution due to Carbon monoxide and Sulphur dioxide in that area. (News 16-03-97).

An alarming report has come from London that the **mortality rate** due to cancer is 20% high in children who born in the vicinity of pollution centers like oil refineries and cement factories. A study carried out in England, Scotland and Wales during 1953 to 1980 told that the mortality rate due to cancer in children below the age of 15 was much more higher who were born within 4 km. of the roadways and railways emitting vehicular pollution. It is also stated that the mortality rate was the highest in children who born within 5 km. of the plant using petroleum fuel (News 12-04-97).

Chrome ulcer is common with the use of Chromium and Bichromates. 30% workers were found with dermatitis and nasal septum perforation i.e. hole in noses (News. 10-07-98).

Greenhouse effect :

Another report from WHO has warned that the increasing proportion of CO_2 in environment will increase diseases like Malaria, Cholera, Dengue etc. and children may die due to such air pollution. Scientists are worried that proportion of CO_2 has been 30% increased during last two centuries. The increasing **greenhouse effect** increases earth temperature. It is well known that most of the factories and vehicles continuously emit tons of Carbon dioxide in the air. This greenhouse gas acts as a barrier in atmosphere and stops the reflected heat from the earth to go up. Therefore the temperature of the earth increase. Ozone depletion also adds to this. We are cutting the trees, which consume Carbon dioxide. The ultimate result in the continuous increase of CO_2 in atmosphere, which makes the earth a furnace ! It is only the wind (the God-gift) that dilutes and disperses this effect. They apprehend that 3 to 4 degree temperature rise will kill many birds and animals like tortoise. Warning is given that if China and India will not control their greenhouse gases in time, it will create serious problems. China has recently signed an International treaty to reduce her greenhouse gases. Signatures of 55 countries are necessary to implement this treaty. Water pollution in India has crossed its permissible limits. In industrial cities and surrounding villages, the water is not drinkable. Environmental erosion will frequently bring scarcity in India and Asia, it is seriously warned. (News 16-04-97).

PTI News from New Delhi published that in Bangalore city (known as Silicon Valley of India), quality of **'semen'** is being deteriorated due to air pollution. It is warned by the Reproductive Health & Research Centre of Bangalore that the quantity generation rate and deficiency of spermatozoa in male semen have been changed during last five years and the male fertility (reproductive health parameters) is decreas4ed due to polluted environment (News 2-06-97).

Scandinavian Research Report was also published on 21-05-94 to open our eyes. It covers studies in 20 western countries and states that during last decades, noticeable decreases in "Sperm Count' is reported. Comparing with a man of 1930, the present man produces only 50% sperm ! In England out of 20 couples, one couples has no potency to get child. This was due to the effect of pesticides on food.

Director of Science and Environment, Dr. Anil Agrawal, aid that the 'sperm count' of Indian males has been decreasing. A study report of males living in a polluted area in Mumbai, it was found that less than 30% of males were showing normal quality of their sperm. Excessive pollutants in that area were Lead, Sulphur dioxide and suspended particles in air. Chemical pollution causes cancer, heart troubles and hormones irregularities (News 12-07-98).

Overseas Development Administration (ODA) of England has warned that the air pollution has not only affected the human population, but it has reduced the productivity of some crops to 40%. Pollutant like SO_2 & NO_2 have adversely affected crop of wheat, rice, soyabean, groundnut, cotton and mango and it reduces healthful elements and tissues of leaves etc. Another report of WWF-India states and these pollutants make the crops more sensitive to pesticides and diseases. (News 9-6-97).

In USA the total SO_2, release is nearly 9 x 10^7 tons in a year. NO_x is believed to be involved in global warming. CO2 emission in air is some 5 billion tones per year. Earth temperature will be increased gradually. Carbon particles in soot, smoke etc. from combustion processes are undesirable. Fly ash generated from the combustion of pulverized fuel pose serious pollution problems.

A report of the Central Pollution Control Board says that the vehicles in India emit some 418 tonnes gases per day. These gases include CO, NO_x and hydrocarbons, and constantly affect our health (News 9-6-97). Today some 2.7 million vehicles emit CO_2 in air (News 14-9-97)

Five young boys of 14 to 18 years, died at a time when they were sleeping in their house after forgetting to stop a portable power generator, which was used to see TV in absence of power supply. It is reported that doors and windows of the room were closed. What could be the causes of their death during midnight ? Certainly the toxic gas generated from the fuel exhaust and containing CO, NOx, other hydrocarbons and oxygen deficiency (News 6-8-97).

In a seminar organized by the Institute of Engineers (India) at Ahmedabad on the subject of 'Urban Landscape and Gardening', it was highlighted by the environmental engineers that in Ahmedabad City only the motor vehicles emit daily some 240 tonnes Carbon monoxide, 30 tonnes Hydrocarbons and 9 tonnes Nitrogen oxides. It was pointed out that the main air – pollutant in our country is Sulphur dioxide, which is mostly generated by industries. It was suggested for fighting these hazards and keeping the environment clean, to plant and nourish as many trees as possible. It was said that tree plantation in 500m2 area reduces 70% pollution. One Peepal tree (which we consider holy) throws 1700 kg Oxygen in air in one hour and eats 2300 kg Carbon dioxide as its food ! The natural pollution control device !! (News 22-8-97).

People have cut so many trees that it is apprehended that in the 21st century we shall have to face the Acid rain.

One higher official of the Central Environment and Forest department and a member of the Central Crisis Group visited the HPCL refinery to investigate heavy fire incident of 14-9-97, told newsmen that there are 1254 major accident hazard factories in India, of which 300 are in Gujarat. The department has prepared state-wise lists and identified other 12702 hazardous industries also. Near Delhi there are 23, in Mharashtra 278 and in Bihar there are 82 major hazard installations that can cause great damage. The units storing petrol, LPG, ammonia, chlorine, nitrates, etc. in bulk quantity, can be proved the most disastrous. 34 plants of HPCL can causer emergency at any time. Such units are told to submit safety reports and emergency action plans (news 29-9-97).

The Gujarat High Court ordered to reduce 50% production of 72 polluting factories at Vapi (News 30-10-97). The Supreme Court ordered to close as many as 168 industries in Delhi. About 25000 workers became jobless and no salaries and compensation were paid to them. Five major trade unions made demonstration saying "SC rulings have put us on starvation. Article 21 of 'Right to People' was interpreted in favour of public but no in favour of workers. (News 10-01-98. it is the health hazard of pollution only that invites such cry, closure or reduction in production and employment. This sequence may continue till adequate safety measures result in prevention of pollution.

In the State level meeting of GPCB at Gandhinagar, it was reported that some 9000 chemical units out of total 20000 units in the State, pose great danger to human health due to air and water pollution. 3267 closed units due to High Court's order were allowed to restart after constructing the effluent treatment plant (News 15-10-99).

CAG Report (Comptroller and Auditor General) as on 31-03-2001 of Govt. of Gujarat published an audit report. A few salient points are as under.

1. Rs. 3.38 crores given to GPCB to adopt clean technology during 1994-99 was not all utilized !

2. There was no coordination of GPCB with other Department to stop water pollution.

3. No sample from any Sewage Treatment Plants of five Municipal Corporations was meeting the standard.

4. Two major sewage treatment plants of Ahmedabad Municipal Corporation were illegallary discharging effluent without treatment !

5. 83 out of 110 local Panchayats have no gutter system.

6. Observations regarding common effluent treatment plant (CEPT) in industrial areas were also not good. Expected treatments were not given by the member industries before sending effluent to the CEPT. Discharge of CEPT was also not meeting the standards. One CETP at Vapi was directly discharging the effluent (without treatment) into Damaganga River ! Many fishes were died due to this. Only a notice was issued by GPCB in this regard.

7. Villages containing high fluorides in water were increased from 803 to 1304 from the year 1997-98 to 1999-2000. Villages containing TDS (Total Dissolved Solids) in water were also increased from 567 to 960 during this period. More than 100 villages were having excess nitrate in water.

Such report are available for many departments and for many years ! Who makes use of it and who tries to improve the condition is a big question. Is it not a problem of Safety ? Intention of citing such alarming reports is to awake and implement the concept of safety.

Because of gases coming from Vapi GIDC estate, the monsoon rice crop at Karvad village was greatly damaged. Because of water pollution is Sabarmati River, thousands of fishes were found dead (News 26-8-98).

The problem of solid waste disposal is also not solved. Throwing it in river or sea can kill fishes and other living creatures. The National Plastic Waste Management Working Group has recommended prohibition on recycling of dirty plastic waste as it contains impurities (News 12-10-97).

Dangers of Pesticides :

After dumping an average of 50000 tonnes of pesticides annually in the past 30 years to improve our agricultural yields, the land is so poisoned with BHC and DDT that, even if spraying were stopped, the chemicals will linger on for 50 years more ! The studies have shown that high percentages of these pesticides are being found in cow's milk. Now we will have to turn towards eco-friendly bio-pesticides not injurious to land.

Ahmedabad Consumers Education & Research Centre collected (in the year 2000) from different parts of the country 13 samples of flour being sold by big-named companies. All the samples found containing DDT ! Agricultural use of DDT as pesticide is banned for more than 12 years. Even then DDT, Aldrin and Dieldrin have been repeatedly found in the samples f flour, eggs, milk, butter, ghee, pulses, fish and vegetable oils. Contaminated food by such pesticides, after entering the human body, increases possibility of many diseases.

Samples of mothers' milk have shown the DDT content six times more than the maximum residual limit (MRL). Such a heavy overdose stops the child growth. A study conducted by Indian Council for Agricultural research showed traces of DDT and Aldrin in 57% of vegetables. Even strain (grass) for report of 'Toxic Link', about 147 types of pesticides are manufactured in India of which Government has prescribed MRL for 50 pesticides only. We do not know MRL of other 100 pesticides !

International Development Research Centre of Canada says that about 10,000 people die every year and about 4 lakh people suffer adverse health effects, due to pesticides poisoning.

Study reports state that effects of pesticides and preservatives for our food, fruits, milk and vegetables are dangerous to our health.

In China only in 1995, in 27 States, 48377 cases of pesticide poisoning were reported, of which 3204 were fatal ! 7500 cases were due to Parathion and Mithamedophos. Food and Agriculture Organization (FAO) and United Nations Environment Programme (UNEP) declared additional five Organophosphates (Mithamedophos, Methyl parathion, Monochrotophos, Parathion and Phosphamedon) the most poisonous, and imposed ban to export them without the consent of an importing country. Total there are, so far 29 such chemicals having lethal effects. The world market of pesticides was of Rupees thirty thousand million dollars in 1996 and is rapidly growing (News 25-9-97). Is it not a struggle of wealth (so many million dollars) verses health (more than the mere cost of so many lives) ?

A young daughter (Age 15) and her mother both died when they took Aluminum phosphide tablets for suicide. This pesticide tablet when mixed with body-fluid generates phosphine (PH3) gas, which kills a person (News 28-10-99).

At a time 7 peacocks and many other birds died in Rundel village near Borsad, on 3-12-97, due to pesticide poisoning in a farm. (News 4-12-97).

Scientists of National Institute of Nutrition, Hyderabad warned about Aluminum poisoning and effect on CNS and brain due to excessive use of acidic food prepared in aluminium vessels (News 6-9-98).

5000 doves trapped in paralysis and showed symptoms of pocks, tumour and cancer in Mumbai due to contaminated jawar given to them (News 23-1-98).

'In India where 80% people depend on agriculture, more than 20% males may lose their potency to become fathers in a coming decade', says a young research biologist Shri Nimish B Vyas at

Ahmedabad while talking on effect of excess toxicity in pesticides and insecticides. 'In America and Europe voluntary organizations are warning people about this' he ads. In India also such awareness is timely required. (News 23-6-98).

Adulteration:

Adulteration of oil of Orgamon Mexican (an American Plant) in edible oils hospitalized thousands of people and caused disease known as Dropsy. It attacks liver, kidney, heart and ratina (News 11-09-98).

Mixing of Palmolive in groundnut oil is very common.

More than 20000 adulterated food products have been reported and many more are being added daily. Some 30 years before one science magazine Lancet had warned that every person in Great Britain was adding an average 3 lbs poison in his stomach. Because of more adulteration in our country, this figure could be 30 lbs nowadays. A list of some adulterated substances in given in Table 1.2.

Table 1.2 : Adulteration of Substances.

Substance	Adulteration	Health Effect
Rape seed oil	Orgamon Mexican	Heart & eye
Edible oil	White oil	Cancer
Turmeric	Lead chromate	Paralysis
Wine	Methanol	Blindness
Apple & other fruits	Lead arsenate, Lead chromate	Paralysis, Blindness, anaemia
Tinned food	Cadmium	Food poisoning
Meats & vegetables	Celurojela	-do-
Fish	Formaldehyde	-do-
Tea, Water & toothpaste	Fluorides, Bone powder	Teeth & bones
Bread	Fuserium preminehum rozium	Food poisoning
Polished rice & puses	Asbestos	Cancer
Ice-cream & Sweets	Sodium carboxyl methyl cellulose, Metanyls yellow, Rhodamene B, Orange 2.	Cancer
Capsicum, Confectionary & Ice-cream	Polish, Nonedible colours	Injury to stomach
Flour	Sand & dust	
Tea	Colour & iron powder	
Milk & Milk products	Starch	
Pure Ghee	Vegetable Ghee	
Chinese Food	Monosodium glemate	
Chocolates	Vanillin & Propylene glycol	
Jaggery, Mushroom	Zinc sulphide, Bleaching powder.	

In bulk capsicum powder exported by Bombay Merchants, a carcinogenic substance 'Sudan red-1' was mixed. Spices Board of India prohibited such export.

As per one report of Indian Council of Agricultural Research, 60% food grains contain pesticides. In most of the samples, level o pesticides was found 14 times more than the maximum tolerance limit (MTL).

Thus the adverse health eff4ects due to food adulteration are very serious (News 11-9-98).

Because of adulteration in seeds for sowing, farmers suffer loss every year. The crop becomes poisoned because of pesticides and pollution. A mixture of earth and cadmium is sold as Phosphatic fertilizer, blue ink as pesticide and chalk as DDT. Methyl parathion is sprayed on cauliflower to make it whiter and green vegetables (e.g. lady's finger) are dipped in copper sulphate to make them greener. Samples of mothers' milk have shown excess DDT (17.18 ppm) and DDF (26.66 ppm). This can be a cause of mother's cancer. Poisonous chemicals in dead fishes were found 2000 times more than their safe limits ! Milk sold in Uttar Pradesh was found synthetic i.e. made of caustic soda, urea and soda solution ! American Soyabean is made by a technique of genetic engineering. 44 types of diseased bacteria were found in 10 lakh tonnes wheat imported from Australia. A vital cause of disease like cancer, heart attack, blood pressure, blindness, infertility etc. is such criminal adulteration (News 16-10-98).

12 types of food grains and other atables being sold in Gujarat were tested in laboratory and the results are as under :

72% of dairy product samples were found poisonous, 50 to 60% samples of grains and pulses, 23% samples of wheat flour and 90 to 100% samples of vegetables were found containing DDT and BHC. The contents found are given in Table 1.3 :

Table 1: 3 : DDT & BHC in Food grains

Sample of	DDT (PPM) (Safe limit 0.5 to 5.0 ppm)	BHC (ppm) (Safe limit 0.01 to 2.0 ppm)
Wheat	5.15	18.07
Tuver Dal	7.75	5.86
Rice	7.80	24.82
Ground Nut	7.24	4.12
Butter	6.15	4.62
Cheese	1.03	0.88
Ghee	2.03	1.34

DDT destructs body resistance and CNS and increases cancer possibility. BHC damages liver, kidney, embryo, generative organs, body resistance and also responsible for cancer. Use of these two pesticides needs complete prohibition (News 27-6-2001).

A report of a committee constituted by the Delhi Court says, 'Oxytocin, a hormone being given to cows and she-buffaloes to get more milk, is a slow poison and brings kidney and liver trouble' (News 13.09.99).

'Green fodder – Juwar, Makai, Bajari, Rajko etc. – contains poison', the Animal Husbandry Directorate of Gujarat State warned it and precautionary measures were suggested for the farmers. Unripe, soft juwar emits Hydrocyanic acid, urea fertilizer generates Nitrate, green Rajko gives 'Seyoniue', Subabul leaves produce 'mymocine' and all pesticides in green grass, fodder or vegetables can generate 'poisons' and kill animals when they eat it. Therefore it is not advisable to give green soft fodder, leaves, vegetables etc. to animals and to give immediate water after such food' (News 11-12-2000).

During summer when demand for ice-cream kulfi and cold-drink increases, it was found that white poster colour and safedo (white powder) were added in the manufacture of ice-cream, kulfi and cream-candy and saccharine was added in cold-drinks and in ince-candy. After detecting such adulteration, Health Officers of Lucknow said that poster colour and safedo add lead in the body and its delayed effect is damage to brain and its control activities and the delayed effect of saccharine is a cancer (News 2-6-99).

Adulteration of urea in milk to maintain fat level, mixing of talc / chalk (Magnesium silicate) in flour and spices, orgamon in mustard oil, starch in sweet, old (renseed) oil in new oil, mineral oil in edible oil, vegetable oil or boiled potato in ghee or butter, molasses (sugar waste) in honey, chalk in salt and sugar are some published reports.

Cadmium used in cigarettes, some antiseptic medicine, colours, chemicals etc. cause hypertension. Aluminum used in antacid drug to cure acidity causes mental effects. Lead and mercury are other metals, which damage brain and kidney.

It is very surprising that one of the reasons of fall of Roman Empire is said to be lead poisoning ! Romans were filtering wine in lead lined vessels and because of drinking of such 'leaded wine' they had mental effects, which resulted into their defeat.

'Health of 70% of our agricultural labour is not good' says the India Council of Medical Research. Its survey states that this health effect is due to pesticides, tobacco dust and genetic diseases like leptosprirasis due to contact with animals (News 4-11-97).

Water Pollution:

The water that we drink everyday is 70% polluted ! Out of 3119 Cities of the country, only 219 have water filtration plants ! And that too covers only 33% of the city population. This massive water pollution is a very serious matter. In India, about two third diseases like, typhoid, cholera, jaundice and diarrhea spread due to water. Many such diseases have full potential to be epidemic (News 12-10-97).

Water Supply Board of Gujarat has published some figures of adverse health effects. These are given in Table 1.4 :

Table 1.4 : Adverse Health Effect of Polluted Water.

Year	No. of People adversely affected by drinking of polluted water
1997	32000
2000	46000
2001	50000

(News 27-5-2002)

New York Times published a report that lakhs of people in India and Bangladesh drink water mixed with Potassium cyanide from water wells. Only in West Bengal 60 lakhs people drink such water, out of which some 3 lakhs have shown symptoms of cyanide poisoning on their bodies. Potassium cyanide can cause cancer. Shri K.J. Nath of All India Institute of Hygiene & Public Health has also warned about this problem (News 12-11-98).

Chennai Health Laboratory tested 191 mineral water bottle samples and found bacteria in samples ! In samples of soft cold drinks also, bacteria and excessive saccharine were found. Ordinary tap water is sold in brand named bottles at the price of Rs. 14 (a price of 1 ltr milk) per bottle ! This may cause typhoid chemicals (BOD & COD) are not safe (News 4-6-98)

16 rivers and 18 lakes in Gujarat have been polluted. The Central Pollution Control Board has identified the most polluted 20 rivers in the country. Proportions of pH, dissolved oxygen and dissolved chemicals (BOD & COD) are not safe (News 4-6-98).

Dr. MGK Menan Committee Constituted by the Govt. of India under the directive of the Supreme Court has added one more warning. It has published that 70% water resources of so-called Golden Corridor (Industrial belt between Vatva to Vapi of Gujarat) have been polluted, people have contracted diseases due to pollution and a great scarcity is caused of drinking water and water for irrigation. It has also reported hat at 40 places in Gujarat, hazardous waste is dumped illegally and no action is taken by GPCB (News 4-4-2001).

A report of pollution effects due to chemical factories from Atul to Vapi is published in a Newspaper of 18-10-98. It states that production of Hafus mangoes has been decreased ten times in village Haria and water in well have become coloured. When water is filled in a glass, a thin layer of deposits is visible on inner surface of the glass. Red water is thrown in Khadi (ditch) by three pipelines of one-foot diameter, even animals do not drink this water and whenever they drink they die. In winter very bad smell comes from nearby factories. Fishes die in sea and railway bridges are rusted. Fishermen are in great trouble as they do not get fished nearby and have to go far in deep sea. Because of chemicals in water, hairs on their legs are removed and they feel burning. As per the statement of Kolka villagers some 40 to 50 people have been died because of cancer during last 5 to 7 years. Poison through fishes also affects.

Billkhadi near Vapi is full of dirty water. Solid and thick oily waste is thrown here and there on the bank. Thick yellow liquid is drained in Damanganga River. Crop in many villages is destroyed. Because of fog in polluted air, it becomes difficult to see even at a 50 feet distance. Because of the worst pollution of water, the surrounding villages have been declared as no source villages. Coloured water comes from hand pumps. Solid waste is brought and thrown near houses during night hours. Some scattered public agitations were going on but ineffective.

Another report of water pollution is also published on 29-12-2000. it states that water in 22 talukas of Gujarat has become heavy because of Sodium, Iron and Calcium ions. Less Dissolved Oxygen (DO) and high COD, Cadmium, TDS, Mercury, Fluoride, Manganese, Chromium and heavy metals have been found in water in these talukas. About 10% area of the State has been polluted and has created threats to the **public health**. The Golden Corridor has become the Black Iron Corridor.

Alang shipyard has heavily polluted the coast of Bhavnagar district in Gujarat. During last two decades, thousand of tons of oil and chemicals have been thrown into the sea while breaking the ships. One drop of oil kills all aquatic lives from 25 liters of water. Marine tortoise, mangroves and aquatic animals are being died day by day due to this coastal pollution (News 4-1-2007).

Out of 19111 villages of Gujarat State, inland water of 1408 villages has become salty and therefore not drinkable. 2826 villages have fluoride mixed water. Such salts dissolved in drinking water cause damage to kidney, bones, teeth and blood constitution. Salty water becomes heavy and not useful for washing clothes and for agricultural purpose (News 5-7-2001).

Air Pollution :

"Throughout the day the chimney spews coal dust. We can feel it in the air" said a rickshaw driver and the worst affected people living within a kilometer of one Rayon factory at Veraval, Saurashtra. A BMS union leader also complained of continuous air pollution. The company authorities deny and put forward the industrial safety and pollution control awards won by the factory ! Residents of 30 housing colonies on the 80 feet road are badly affected (News 4-10-97). The similar problem of coal dust in surrounding area was also continued in the vicinity of a textile mill at Navsari. Our intention is not to criticise anybody but to highlight the struggle of health v/s wealth and to draw attention to protect the health.

A survey carried out by the Central Pollution Control Board has reported some figures of air pollution in tons/ day in five major cities; Delhi 1046.30, Mumbai 659.57, Bangalore 304.47, Calcutta 293.70 and Ahmedabad 292.73. Police personnel working on roads have 10 to 25% more diseases of lungs. Lead fumes from vehicle – exhausts directly enter into lungs and cause TB, asthma and other lung-diseases. Unleaded petrol is recommended but benzene content in it can cause cancer and skin disease ! To reduce its effects catalytic converter is suggested.

Despite of enforcement of all pollution control rules, the developed countries emit every year 150 lakhs ton Carbon monoxide, 10 lakhs ton Nitrogen oxide, 15 lakhs ton Hydrocarbons and millions of tons of Carbon Dioxide in air. Some 70% of air pollution in the world is in the developed countries. Some 80% of the cancer – patients in the world are due to the polluted atmosphere ! (News 5-11-97).

In China, 3 lakhs people died during 1994 to 1996 and in India, 52000 people died in 1998-99 due to air pollution. In blood samples of 100% children in Shanghai and 64% children in Delhi, Lead content was found excessive. During 1950 to 1999, 200 thousand million tonnes Carbon has been added on the earth. During last century the global temperature is increased 14.57^{o}F (News 9-9-99).

Because of the financial loss due to injuries, deaths and degradation of resources caused by pollution, India loses every year some 80000 million dollars, says the World Bank. Because of increasing industrial and urban pollution, excessive land use in villages, destruction of forests and tremendous use of water resources, this situation increases. In South Asia main environmental problems are deteriorating quality and scarcity of water, air pollution and poor water management (News 9-10-98).

Gold and Silver refinery furnaces in Ahmedabad were reported causing heavy air pollution. Welding metal Cadmium causes kidney damage and high blood pressure. NIOH is given a job to conduct survey for health effects (News 29-10-98).

The dangerous health effect of air pollution is again reported. American Lung Association reports 5000 deaths every year due to asthma. During last 15 years, 61% increases is noticed in asthma-patients. Out of 150 lakhs asthma-patients in USA, 50 lakhs are children. They have to carry an inhaler pump daily in their schoolbag to use it by mouth when asthma attacks. American Lung Association published a ‘Family Guide to Asthma and Allergies’ and highlighted this increasing disease of the modern world. IN near future the asthma may overtake the spread of cancer and AIDS if the dust and air pollution are not controlled. (News article 5-11-97).

The Social Infrastructure Development Board of Gujarat has published that the GPCB has been failed to control the industrial pollution, most of the cities in the State ore covered by the excessive emission of SO_2 and its 100 to 500 µg detected level (against 60 µg permissible level) makes the cities ‘gas chambers’ and invites many diseases of eyes, throat, skin, fingers, hearth, breathing, blood circulation and cancer (News 6-1-2001).

Daily we inhale some 14 kg air, which contains some 6 kg toxic gases like CO2, SO2, Ammonia, Lead, hydrocarbons etc. In Gujarat complaints of allergic cough have been increased 20 to 25%. Health effect of polluted air is equivalent to smoking of average 20 cigarettes per day. One of the reasons of decreasing sleep in industrial cities is also the polluted air. In Delhi a trader has started a business of providing clean air at the rate of Rs. 180 per hour ! (News 17-3-99).

23 cities of India are exceeding air pollution levels and every year some 40000 people die due to environmental pollution. Every year Rs. 4550 crores are wasted in medical treatment of pollution sickness. Thus says the WHO report. Suspended particulate matters (spm) are 3 times more than the WHO limit. Vehicular air pollution in Delhi, Calcutta and Mumbai are 65%, 52% and 30% respectively. Vehicles emit NO_x, SO_2, hydrocarbons, lead etc. Due to inhalation of these poisonous gases people die earlier. Diesel exhaust is most dangerous. It harms 10 times more than the leaded petrol. It can cause

direct blood cancer. Unleaded petrol in India contains benzene, which can cause lung and blood cancer. Lead in petrol causes brain damage in children. Therefore use of leaded petrol is prohibited in America, Japan, Canda, Austria, Sweden, Brazil, Columbia and South Korea. Process of removing lead from petrol is cheap. Still 90% vehicles in India run by leaded petrol. In Gujarat, solvent and kerosene are mixed with petrol. Are these petrol pumps not the killing centres ? (News 18-12-97).

Because of many complaints of kerosene mixing in auto-rickshaw, the ADC and also DSO raided at night and found sale of kerosene to rickshaw- drivers in Surat. Some 4400 litres of free sale kerosene was seized. At four petrol pumps, samples of petrol and diesel were found adulterated. Such is the condition of vehicular pollution in many cities in our country (News 23-11-98).

During 1980 to 1990, loss due to pollution was Rs. 131298 crores, as calculated by the National Environmental Engineering Research Institute, Nagpur. Losses due to cutting of forests and air and water pollutions are day-to-day increasing (News 21-05-98).

Dr. Rashmi Mayur, an advisor of United Nations Environment Programme warned at Ahmedabad on 5-6-98 (World Environment Day) about the damage being done to the forests and forest products; wildlife; rivers; seas, land and all natural products.

He told that 50% land and 70% water in Gujarat have been polluted. Most of the land in Kheda District has become salty. Ahmedabad has been declared the most polluted city by the Sulphur dioxide. About 2500 Km^2 forest area was lost just in last one year in India ! If environmental balance will not be maintained, skin cancer may increase at the annual rate of 5%. Instead of depending on the Government, people should make the movement. Manpower and awareness should be created (News 6-6-98).

During last 10 years, vehicles have been 3 times increased in India. In 1986, there were 1.1 crore vehicles registered. This figure rose to 3 crore in 1995. Out of this, 35% vehicles are in 23 mega cities. Maharashtra and Gujarat are at the top with 36 lakhs and 30.2 lakhs vehicles. Planning and Programme Implementing Ministry has warned that the tremendously increasing use of vehicles is polluting the environment by toxic gases like CO, CO_2, SO_2, and hydrocarbons (News 31-1-98).

As per report there was an addition of @ 6 lakhs vehicles during 1990 to 1999 in Ahmedabad city only reaching a toll of @ total 11 lakhs registered vehicles in the city. Out of @ 50000 auto-rickshaws, 70% auto-rickshaws add 3 to 4 litre kerosene daily. PUC machines for checking fuels do not check Benzene, Sulphur and Lead contents, which are the main pollutants ! These three contents must be decreased from petrol and diesel (News 28-11-1999).

Coal bed methane (CBM) can be used as a new fuel in the next century to reduce vehicular pollution. It is successfully used as a commercial fuel in USA, Germany, France, Poland and Czech Republic (News 4-12-1999).

Two persons died in a bathroom at Ahmedabad due to the use of gas-geyser. Oxygen deficiency due to LPG burning and CO generation by incomplete combustion due to less availability of oxygen in a confined room can be proved fatal in this way. Other 3 persons were also died in the similar situation during last one year (News 19-12-1999).

Tobacca Poisoning :

WHO Report says 3.83 lakhs people died in India and 9.13 lakhs people died in China during 1998 due to tobacco eating and smoking. By the year 2030, some 1 crore people in the world would die due to the use of tobacco ! Female proportion is day-by-day increasing in this regard (News 31-5-99).

Another report of WHO says that by the year 2030, death toll due to tobacco may reach up to 10 lakhs per year in the world.

India produces 4.40 crore kg tobaccos every year, of which 80% is consumed in the country. In other words, about 3 crores people smoke/ chew tobacco in one or the other form in our country. In India about 1.90 lakhs tobacco cancer patients are added every year ! Rate of heart attack is also more in tobacco users. Indirect smoking is also dangerous. Many poisonous gases are evolved while smoking of tobacco. Exposure to tobacco smoke causes asthma and lung cancer. 31st May is celebrated as Tobacco Opposition Day in the world. Awareness against tobacco poisoning is most necessary. (News 31-5-2001).

A Washington Report warns about another danger of tobacco smoking. A study report of 60 smokers is published by American Scientist. It reveals that if a person having high blood pressure smokes, chances of his being impotent increase 27 times ! Not only that, but possibility of being impotent is 11 times more in those who have left smoking comparing them with those who do not smoke.

One crore Americans and one lakh British of age group of 30 to 40 have become impotent due to the adverse health effect of tobacco smoking. (News 31-05-2001).

Radiation and Other Hazards :

An Environmental Assessment Division of **Bhabha Atomic Research Centre**, Mumbai conducted study of 81 employees who died due to cancer and who served from 1971 to 1992 with their age-range of 20 to 59 years. Dr. K.S.V. Nambi and Y.S. Maria in 'Indian Journal of Cancer' published this study report with the conclusion that an incidence of cancer was certainly higher in employees working in **atomic radiation** zone than those working in non-radiation zone. The effect of radiation was responsible for higher incidence rate of cancer. (News 25-12-97).

Fifty percent of the X-ray machines of our country are unsafe and may cause cancer. Higher doses of X-rays can cause death or cancer as a delayed effect. Thus said the Atomic Energy Regulatory Board and the Council of Scientific & Industrial Research based on their survey started in 1994 (News 17-12-99).

Warnings have been issued to continue very old atomic power stations. Out of some 400 atomic power stations in the world, 170 are 25 years old and 60 are 30 years old. Radioactive wastes thrown by Tokyo Electric Corporation killed lakhs of aquatic lives in the sea. Message of Chernabil accident in 1986 in Russia is eye opening. Stringent safety rules, safe disposal of atomic wastes and emergency planning must be strictly followed.

Mr. V.R. Singh, the Head of Instrumentation and Biomedical Ultrasonic Department, National Physical Laboratory, New Delhi, warned about the Hazards of Ultrasound Devices being used in hospitals and nursing homes. He told that such machines would injure the health of both, the operator and the patients. Sound waves above the permissible frequency cause damage (News 26-02-98).

Forest are being cut heavily and at the fastest rate. Some 6 billion hectares forests and jungles have been reduced to 3.2 billion in the last century. This is the removal of environmental protection and invitation to new hazards. But the greatest hazard of hazards is the P**opulation Explosion** ! Every minute 54 babies are added in India (like addition of Australia population at every eight months). No facilities will be sufficient to serve this ever-increasing population. This will certainly create many problems of health and safety also (News 19-4-98). India will become the highest populous country in the world by 2050 (News 23-03-99).

A report of a scientists' committee of European countries has warned about toxic effects of plastic toys for children. Most of the toys are made from plastic waste or poor quality colours and chemicals.

Chemicals used to make toys soft and attractive to put into mouth are dangerous. In USA, Foods and Drugs Department has made rules for safe manufacture of plastic toys (News 5-10-98).

A common solid waste – polythene bags – has caused fear on animal lives. Cows and other animals eat these plastic bags (waste) thrown here and there. They also cause problems when choked in pipelines. Therefore the Rotary Club of Gandhidham raised a move to motivate people to use paper bags instead of polythene bags (News 28-10-98). Use of thin plastic bags (<20 microns) has been prohibited under Recycled Plastic Manufacture and Usage Rules 1999.

'**Lead poisoning** is increasing in the blood of our children' alarming news came from a survey carried out of some 22000 samples by the George Foundation. Children below 12 years are badly affected in our major cities because of the petrol pollution from thousands of vehicles. In 34% children lead level in blood has crossed the international level. It reduces the child IQ by 6%. Environmental protection is highly needed for Indian Children (News 16-03-99).

A study report of NIOH (National Institute of Occupational Health), Ahmedabad was reaffirmed this fact and stated that due to high lead content in blood, children's IQ can be decreased and due to adverse effects on pregnant women, intelligence of future babies would also decrease (News 11-1-2000).

Hazard of Modern Living :

Sick building syndrome due to internal pollution generated by noise from water on air cooler, air-conditioner, generator, printer etc. in homes or offices causes breathing trouble, deafness, sleeplessness, tiredness, headache, eye burning etc. Chemical rays from paint, varnish, nail polish, boot polish, mosquito liquid / gas pesticide and Carbon monoxide from fuel burning cause lung diseases. Long working on computer causes breathing trouble, deafness, sleeplessness, tiredness, headache, eye burning etc. Chemical rays from paint, varnish, nail polish, boot polish, mosquito liquid / gas pesticide and Carbon monoxide from fuel burning cause lung diseases. Long working on computer causes eyestrain, which needs antiglare screen. Rooms having gas-stove, kerosene stove, furnace, electric heater must have exhaust fan or sufficient windows otherwise fuel gas causes cough etc. Air fresher, deodorant, hairspray, varnish, polish, wood-binder (resin) etc. spread irritant gases in air.

Use of cosmetics is day by day increasing with an increase of beauty – parlours and otherwise. Chemical cosmetics contain many harmful substances like silicon jell begs to increase breast, hydrocarbons, solvents, para-phenylenediamine (hair-dye), ammonium perceulate or thioglucose etc. No toxicity or standard (e.g. IS) is mentioned o such products. Therefore use of such chemical soap, cream, powder, foundation, nail polish, lipstick, bleach, wax, hair-dye, hairspray, hair-remover, aftershave lotion and cream, perfume spray etc. should be avoided or minimized. Their health effects are adverse. Non-chemical, herbal or Ayurvedic cosmetics may be used. Before their use, body test is necessary.

Warning to drop use of cosmetics must be heard by the women of the world. National Institute of Occupational Safety and Health of London said that 900 chemicals used in cosmetics are toxic. Botox i.e. Botulinum toxin is highly toxic. If 1 gram is sprayed in the air, it can kill many people. Benzene, Formaldehyde, toluene, collagen, acuten and laser rays can cause cancer also. They disturb body hormones; remove sex desire and damage lungs and mucus membrane (News 27-11-02).

Simple one hour walking and deep breathing or Yogasana can preserve health and beauty.

Most of the cosmetics contain toxic and flammable substances like benzene, formaldehyde, coal tar, lanolin (wool grease), phenylenediamine, phenoxyethanol, paralence etc. which may look non-hazardous in test tubes but they become hazardous when entered in skin or become old.

They are used in eye shadows, shampoo, skin-cream, blushers, lipsticks, mascara, hair spray, perfumes, moisturizer, toothpaste, soap etc.

Nail polish contains very hazardous chemicals like Acetone, Sprit, Methyl benzene. Phenol, Formaldehyde. These chemicals destruct natural shining of the nails and if ingested through fingers and mouth, they damage stomach and liver and may cause cancer if taken excessively or repeatedly.

Individual level of such chemical may be less than the 'permissible limit' as claimed by the manufacturers but their synergistic or total effect due to prolonged use can cause allergic reactions and serious damage to body hormones and make us ugly or sick or weak after some time. Daily use of lipstick amounts to @ 60 kg during lifetime'

Not only eye or skin sensation but they also cause cancer, disruption, neurological damage, miscarriage and harm to child in mother's womb.

Book like 'Protect yourself from the Hidden Dangers of Cosmetics' and many warnings are published for our safety. Do we want to awake and forgo such mad use of the cosmetics or not? (News 285-03)

Consumer Guidance Society of India, Mumbai has warned the women regarding their *Sindur* and **Bindiya** that they are now poisonous! **Sindur** contains Lead oxide and kumkum Mercury sulphide! Sticker type bindiyas (forehead points) can also impair the skin. Indian Standards should be prescribed for non-toxic chemicals to be used in such cosmetics (News 18-4-98).

Exceeding use of hair-dye also increases lead level in blood; it is so reported by Dr. T. Venkatesh, the Chairman of St.- John National Academy of Bangalore. It reduces memory, adversely affects CNS and brings unconsciousness sometimes (News 17-399).

Flavours and Fragrance has also been poisoned by chemicals! Artificial flavours and fragrance of strawberry, raspberry, mango, apple, guava, banana, sandalwood, soaps, shampoos and even of milk are manufactured from various chemicals like Amy I acetate, Amyl butyrate, Amyl valorate, Ethanol, Anicyl formate. Benzyl acetate. Benzyl isobutyrate. Butyric acid etc. Some artificial tastes are generated as under:

Taste of	**Generated by**
Popcorn	Methyl-2-dylecton
Apple Milkshake	Ethyl-2-methyl-butirate
Almond	Benzaldehyde

Milkshake contains alcohol. French-fries (potato wafers) are fried in cow tallow and freeze by compressed Ammonia gas. Six months stale items are also sold after refrying.

Health effect of such junk food or fast. food is to spoil our stomach, CNS, liver and kidney. They cause acidity, hypertension and food poisoning. They increase fat and weight, which in turn invite other diseases. 'World Watch Institute' says that some '12 crores people of the world are 'overweight' due to eating of such fast food and French-fries. It is also reported that some 2 lakhs Americans get food poisoning everyday and some 14 people die daily due to food poisoning (News 18-6-03).

The use of ultramodern equipment has also posed danger. High frequency electromagnetic waves from kitchen micro-oven, cellular phone, pager, hair drier, washing machine, electric blanket, room heater, personal computer, TV, video display terminal etc. can cause serious health hazards like leukaemia (blood cancer), brain damage, liver damage, bone marrow injury, miscarriage and adverse effect on body cells and DNA (News 8-12-97).

Similar warning was again issued at the **International Seminar** at New Delhi. 'Excessive use of such electronic equipment (mobile phone, pager. Fax m/c,, micro ovens, hair direr, TV, toys etc.) may cause cancer, skin disease, brain or heart trouble etc. due to electro magnetic field' it was so declared (News 23-12000).

Report published in 'Epidermilogy' journal, by Dr. Andris Stener of Emin University of Germany, states that incidence of eye cancer was found much more in mobile phone users when a group of 118 such users was compared with a controlled group of 475 people not having cancer. Fluid in eye cavity detects phone wave radiation very fast (News 17-1-2001).

As per Dutch report, headache and nausea due to mobile signals from base stations (third generation network) have been reported from public living in vicinity. (News 02-10-2003)

Dry cleaning chemicals (e.g. Perchloro-ethylene) increase 25% more chances of cancer and adversely affect tongue, lungs, neck and blood pressure; it is so reported by the National Centre of Occupational Health and Safety at Cincinnati, USA. (News 3-4-2001)

Dry-cleaned cloths emit Trichloroethylene, which causes nausea, headache and giddiness. Therefore they should be kept in open air for some time.

Warnings about increasing use of **non-stick utensils** are also published. Teflon or M-8C coated utensils are used in kitchen to fry or roast *dhosa, pudla, thepla* etc., as they need less oil, the food does not stick to the vessel and therefore less labour to clean them. Reports have been published that this coated chemical (black or brown) is very toxic and its poisonous effect is found in the blood samples of 90% of the users! It adversely affects unborn child, newly born child and others.

Glaze (lustre) of **ceramic vessels** (e.g. cup-saucer) contains lead: Food and Drug Administration of USA has warned people to know this lead level before using such vessels. It is advised not to store hot and sour eatables for long time in .it otherwise excess lead decreases haemoglobin in the blood (News 28-6-99).

Tin (Kalai) coated or copper vessels are good for health, it is also reported (News 3-6-03)

Colourful festival of Holi has also become unsafe because of the use of toxic colours! Black (Lead oxide), Green (Copper sulphate). Blue (Prussian blue). Red (Mercury sulphate) etc. contain heavy metals which cause skin diseases, kidney failure, eye damage and even cancer. Red powder Gulal contains lead, chromium, mercury, nickel, cadmium, zinc and iron which adversely affect kidney, liver, CNS, intestine etc. All India Institute of Medical Science and Poison Centre of the Central Govt. have also warned about use of these hazardous colours. Natural colours from plants and vegetables should be used. *Kesudo, Haldar, Limdo* etc. are of this group. (News 17-3-03)

CFC (Chlorofluoro carbon) generated from refrigerator and air-conditioner decreases oxygen level in air and in our body. Its result is hypertension, allergy, asthma and lung diseases. Detergent powder on clothes or utensils causes skin disease and more damage if ingested unknowingly. Xerox and laser printers liberate ozone gas. Anything which our nose or eye detects and dislikes, is primarily dangerous. Undetectable dangerous chemicals are also to be studied and avoided from our working atmosphere.

Scrap of outdated computers and mobile phones pose environmental risk. Monitors have heavy metals like Lead, Cadmium and Mercury and a poisonous gas Arsine. These metals release toxins. Therefore their landfills pose environmental hazard (News 10-7-2001).

Australian scientists, after studying two Australian and one British car shops for two years, invented that the smell of the new cars contain 83 mg/ m^3 Benzene (permissible limit 16 mg/m^3). A scientist Steve Brown told that long exposure to such poisonous substance causes headache, nausea, cancer and damage to the child in the mother's womb (News 29-12-2001).

As published in **Current Science**, 1 out of every 20 women in Mumbai has breast cancer! Doctors say that this figure could be still higher and may soon match that in the US, where I out of every 9 women has breast cancer. The magazine explains that this has direct relation with changes in life styles. It occurs as a result of uncontrolled cell divisions that invade healthy tissues and occur via blood stream or body cavities (News 6-1-98).

The world's worst terrorist attack on twin towers of the World Trade Centre, New York, USA, on 11-09-2001, has raised many questions of structural safety of such latest buildings, emergency preparedness to protect people inside such buildings, early detection and avoiding collision of aeroplanes to such high rise buildings, safety of pilots and air travellers, tight security checks for such highjack, isolated and fully protected pilots cabins, revised radar system to detect and avoid such sabotage etc.

Hazards of Allopathic Medicines are also disclosed. Made in and approved by PDA department of USA, a medicine known as REZULIN (drug for diabetes) killed many people in USA and Britain till it was withdrawn in May 2000! It was damaging liver and kidney both. Similar drug FENFORMIN was also required to be withdrawn. Another drug known as PROPULSID and used to control acidity has killed 103 people during the first 3 months of the year 2000. Still FDA gave licence to sell it till 14-7-2000. British Medical Journal has warned that every year 30,000 people die in Britain due to wrong prescription by doctors! (News 28-6-2000)

20 persons died at one occasion of *'Satyanarayan Katha'* on 10-9-2000 in a small house in Shyam Complex, at Surat due to fire and burn injuries. The causes published are (1) Solvent vapour from newly painted walls (2) Fire catching by synthetic sadies and (3) Alcoholic drink brought inside the room. Delayed treatment is also reported due to doctors on strike at Civil Hospital (News II, 12 & 16-9-2000). This incident stresses need of *safety in home* also (See Chapter 31).

Homes and buildings have been ruined to pieces 'in many earthquakes but the great earthquake of 26-1-2001 at Bhuj and other places of Gujarat have again shaken the whole world. The Govt. Reports published in February 2001 give the picture of this mishap: Death 18602, Injuries 1,66,385, animal died 20712, people affected 3.5 crores, estimated loss Rs.21262 crores, loss to industries Rs.5000 crores, fully broken buildings 2,28,906, partially broken buildings 3,97,538, talukas affected 49, villages affected 949, helping countries 38 and so on. *Has it not created many questions for the safety of buildings and safety, of people? Should we not rethink about our present pattern of high-rise buildings, flats, layout and planning? Is it not a sufficient lesson to realize a struggle of health v/ s wealth?* For safety measures in this regard see Part 2.3.4 of Chapter 31.

Report of the **'Soft drinks'** has also not come soft. The Earth Island Journal published from the birth place of 'Coca Cola' i.e. America, notes that in one bottle of such soft drink there are some 40 to 72 mg of intoxicating substances like alcohol, yeast gum, citric acid, glycerine and glycerol obtained from animal bodies. Citric acid content badly affects the bones and teeth, liver and intestine. Modern fast foods also invite bone diseases like 'osteoporosis' (News 30-6-2001).

Centre for Science and Environment, New Delhi, took 17 samples from Delhi, 13 samples from Mumbai and analysed in laboratory. Its Director Smt. Sunita Narayan told that level of pesticides found in these mineral water bottles was 36.4% more than its permissible limit of 0.0001 mg/l. More proportion of pesticides was found in more selling brands like Aquaplus, McDowell, Bislery, Volga, Kingfisher, Hellow, Baily, Finley, Purelife, Prime, Aquafina, Himalayan etc. DDT, linden, Melethion, Chloropirophose etc. were the pesticides. These can cause cancer and damage kidney, liver etc. When branded driving water is poisoned, what to say about safety of other materials? (News article, 13-02-03) Who worries for public safety? Based on inquiry following above report, the Govt. of India banned eight companies including Bislery and Pepsi and suspended their ISI quality mark on their water bottles (News 20-02-03).

A report of the same Centre for Science and Environment (CSE) published the presence of pesticides in Pepsi and Coca Cola brand soft drink bottles collected from and surrounding: Delhi. Four types of pesticides were found containing excessive proportion as under -

DDT	-	15% more
Lindane	-	21% more
Chloropyrifos	-	42% more
Malathion	-	87% more

Laboratory In-charge Dr. N.B. Mathur told that these pesticides can cause cancer and dissolve bones. Some pesticides are capable of decreasing sperm counts in males. The samples showed level of toxins as 0.0180 mg/l against the permissible level 0.0005 mg/l/ specified by the European Economic Commission. Mirinda lemon was found containing 70% more pesticides. *The Members of Parliament raised severe cry and insisted to prohibit such products in India. (News 0708-03)*

The companies have also published then replies in news papers (09-08-03) and denied such findings. Their defence is obvious because they don't wish to lose sales and profits. *One thing is certain that such drinks are neither energy foods nor essential for life. A one rupee product is sold at ten rupees. It drains our money to foreign countries. This is another hazard.*

Pollution Control Board of Kerala, took the samples of wastes thrown out by Coca Cola plant and after laboratory analysis it was found containing Cadmium 201.8 mg/l against the permissible limit of 50 mg/l. Thus even the waste of this plant was containing carcinogenic heavy metal. (News 08-08-03)

Coca Cola Co. has its plants all over the world including India. In Europe and USA, children and youths have made these drinks as part of their diet. In our country also, we see sale of thousands of bottles of Pepsi and Coca Cola at all -places. People should learn lesson from such eye opening news and give up such drinks hazardous to health

Health effects of Cold Drinks have been published. Ethylene glycol is used as antifreeze and anti-drying agent in such branded and non-branded bottles of commonly used cold drinks. It is a solvent and can dissolve our teeth and bone. In addition, it adversely affects our kidney, liver, lungs and CNS. Only 100 ml of Ethylene glycol is said to be a fatal dose.

Another major content of cold drink is Phosphoric acid, which is anti-rusting and analytical agent. Its TLV is only 1 mg / m^3 (STEL 3 mg /m^3) and damage stomach.

Carbolic acid or phenol is also used whose TLV is only 5 ppm and its absorption through skin is very fast. It affects CNS (brain), kidney, liver, pancreas spleen and lung. Its reported fatal dose is 1.5 g (oral It can cause cancer also.

Benzoic acid is used. as preservative whose lowest published toxic dose for skin (human) is 6 mg kg and causes gastrointestinal troubles..

Water used for soft drinks is from unknown sources and not hygienic. It contains heavy metals like lead, cadmium, zinc, sodium, potassium etc. and also reported to contain benzene and methylbenzene.

Therefore total avoidance or prohibition of soft drinks like Coca Cola, Pepsi, Thumps up. Sprint and so on is the only remedy for good health.

Soft drinks made from milk, fruits and vegetables viz. Lassi, Jaljira, Amla, Sugar-cane juice, Gulab, Khus, Ananas etc. should be promoted and used. (News 16-5-03)

After mineral water and cold drinks 'tin packed foods' are also declared poisonous. Inside metal, colours and chemicals are found toxic. Tin-food generates small bacteria known as 'C. botulinam'. This bacteria produces poison. Its fatal dose of only 0.12 micro gram can kill a person. In the name of permitted additive, emulsifier, stabilizer, colour and flavour, chemicals like vinegar, sulphur dioxide, nitrate, nitrite, anti-oxidant (eg. Buchilated hydroxi toluene), saccharine, monosodium glucomat are added. Therefore it is in the interest of safety to avoid such processed and tin-packed or plastic packed fruit juice, jam, bread, butter, cheese, ghee, tomato ketchup or sauce, vegetables, pickles, milk, soup, meat, fish, bear etc. (New 10-8-03).

A report published in 'Experimental Biology' states that **blood stored in PVC bags** becomes contaminated by a chemical known as DEHP contained in PVC. This harmful content adversely affects CNS, liver, kidney and red cells as it was detected from studies on rats. (News 07-08-03)

In the race of acquiring wealth and facilities, are we not doing a suicidal act?.

How many examples to cite? In short, our activities of acquiring wealth are constantly challenging our health. Therefore the concept of safety has become most essential.

3. INDUSTRIALIZATION Vs ACCIDENTS

Industrialization has been defined as 'the process of change in the mode of production to utilise more capital per unit of output, higher levels of technology and management, widening markets with cost economics scale and specialised location of plant, type of plant and labour skills'.

Side effects of such industrialization are to increase accidents, occupational diseases, polluted environment, unsafe working conditions and rapid urbanisation resulting in road accidents and vehicular pollution.

Accidents Facts, 1997, National Safety Council, USA, writes about increasing trend of accidents and injuries in USA as under:

"The un-intentional-injury deaths continued to increase for the fourth consecutive year in 1996 (86777 in 1992 to 98400 in 1996)... The toll of nonfatal injuries is also enormous. About 10207 million Americans need medical treatment every year due to work injuries. The economic impact of these fatal and nonfatal injuries amounted to $444.1 billion in 1996. This is about $1700 per capita or about $4500 per household".

"The five leading causes of such injury and death, which account for 80% of such deaths were unchanged in 1996. *Motor-vehicles, falls, poisoning by solids and liquids, fire & burns and drowning have been the top five causes since 1970"*.

The President of Indian Institute of Chemical Engineers, Ashok Panjwani, told at 49th Annual Session on 18-12-96 at Bharuch - "Industrialisation is the key for the growth of economy. However, growth at the cost of environment is proving to be *detrimental to the society*. There has been a tendency to forget the environment in the process of rapid growth of chemical industries".

"Safety has to be built into the culture. The safety standards of several organisations are equivalent to international standards but in many other industries *safety is still a slogan"*.

The industries increased after the first and second world war and with rapid scientific inventions and applications during the 20th century. The 20th century (1901 to 2000) historically earmarked for the constant rise of scientific inventions, researches, applications, industrialisation and mobility in every walk of life. It cannot be described in short. Here we are concerned with the impacts and ill effects of all such rising and roaring industrialisation as *unwanted evil* for the mankind.

Japan received complaints of environmental pollution and occupational diseases during 1957 to 1960 and it left such chemical industries soon after 1960 and turned toward electronics industry to keep its environment clean. Japan, USA and Canada were compelled to enact strict environment protection laws during this time, which we did during 1986 and thereafter. Our National Forest Policy of 1988 has failed to control environmental pollution. For healthy environment 33% land should be kept reserved for forests, which is reduced to 12% resulting in continuous decrease of birds, animals, vegetation, greenery and clean atmosphere for healthy life.

As per information up to 31-3-1998, total industrial investment in Gujarat was of Rs. 108777 crores. Out of that 54% was for production sector 'and 22.08% for power. 57000 crores was to be invested in petrochemical and chemical industries. Bharuch, Surat, Vadodara and Jamnagar would become the highly industrialised areas. An industrial park at the cost of Rs. 1000 crores was to be sanctioned by the Govt. of Gujarat, to establish chemical and petrochemical industries at Motiberu, near Dholica, Dist. Ahmedabad (News 6-11-97).

In Gujarat 2435 new projects involving Rs. 1250 crores were under various stages of implementation during 1997-98. SSI units increased up to 194000 till the end of 1996. Present installed power capacity of 7721 MW will be raised to 15000 MW at the end of 9th Five Year Plan. Gujarat may secure leading position as industrial state among the Asian countries in the 21st century (News 25-12-97).

Gujarat Infrastructure Agenda: Vision 2010 occupied a full-page advertisement on 27-6-4999. It states 383 world-class infrastructure projects of Rs. 116993 crores! Till 2010 it is planned to have 17477 MW electricity at the cost of Rs. 55167 crores, transportation of 289 million ton cargo at ports, 24 new industrial estates (including 10 port based industrial estates) at the cost of Rs. 7161 crores, 105 new roads with Rs. 19951 crores, 38 new railway projects with Rs. 6533 crores, 49 new water and gutter schemes, II new townships, 51 new systems of urban transportation, 1507 km long gas-grid, new air ports and information technology facilities of Rs. 400 crores. This blueprint of Gujarat, if implemented, will certainly increase rapid industrialisation and in turn safety problems too! It indicates high need of safety technology and accident prevention work.

With such rapid industrialisation, roads and. traffic will also increase. A scheme of Rs. 1400 crores -to develop highways in Gujarat has been sanctioned by the Government (News 1-11-97). Expansions of KRIBHCO plants to produce 1350 MT ammonia and 2200 MT urea both at Hazira and Gorakhpur, at the total cost of Rs. 2314 crores was announced on 6-1197 (News 7-11-97). Such continuous industrial expansion and increasing hazards also increase the need of safety.

It is also reported that only because of the high hazard potential, Vadodara will become the country's headquarters for disaster management. A central control room - the only one in the country - for managing disasters will be set up (under UDMP) there (News 7-10-97).

During last ten years, industries, workers, raw materials, products, pollution, transportation of men and material and their hazards have been increased tremendously. The Central Statistical Organisation (CSO) has reported that industrial production during first four months of 1997-98 was increased by 6.4% comparing with the same period of 1996-97.

The courts are constantly issuing orders to close down the polluting factories. It has also directed to use some less polluting fuel like pentane to decrease vehicular pollution. Looking to the increasing trend of road accidents and falling of school buses in river, the court's directives regarding traffic rules have been shown on TV.

The road accidents are .also increasing as a result of side effects of growing industrialisation and urbanisation. Some figures are as under:

As per report published in 2002, 'India is at No.1 in the world in the matter of road accidents. Sixty thousand people died due to road accidents last year.' (Editorial 18-12-02).

As per report published on 7-2-97, every year some 3 lakhs road accidents take place in India in which more than 60000 people die and @ Rs. 35 crores economic loss results. 20 Lakhs two-wheelers were reported only in Delhi on 1-11-97. From this very day, the helmet was made compulsory in Delhi for all back-riders on two-wheelers. Why? for the purpose of safety only.

The year 1997 was celebrated as Road Safety Year in Gujarat and it is reported that during this year the figure of average daily accidents raised to 95 from the similar figure of 83 in 1996. Figure of daily average fatal accident was also increased to 15, which was 13, in 1996. During first 9 months of 1997 the total road accidents were 25247 out of which 4062 were fatal. Around 50% fatal accidents occurred on highways (News 6-2-98).

In the year 2002, in Gujarat, 4178 people died and 22000 injured due to road accidents (News 13-01-03)

Some figures of road accidents are as under

Road Accidents in Gujarat

Year	Total Accidents	Fatalities	Serious Accidents
1991	27457	3760	5540
1992	26745	4010	6093
1993	27115	4219	6833
1994	26132	4051	6020
1995	30111	4871	7386

Road & Factory Accidents in India (LP News)

Cause	1990	1991	1992	1993	1994	1995
Road accidents	43005	44930	49156	45769	51855	68351
Factory accidents	658	539	549	550	606	616
Others						
Fire	20522	22306	22010	22395	23323	22922
Poisoning	13164	13697	12773	13134	13752	20135
Electrocution	2957	2933	3062	3488	3502	3861

Accidents on National Highway

Years	Total Accidents	Deaths
2000	110000	>30000
2001	100000	>29000

In addition to road accidents/another hazard from vehicles is lead poisoning from their *fuel exhausts*. To avoid this, unleaded petrol, LPG and CNG are introduced.

For more figures of road accidents, see Chapter-31.

In rail-accidents also India is not behind. Two out of five world-worst rail accidents have occurred in India. More than 800 people were died in June 1981 in Bihar when a train fell down from a bridge into the river. A head-on collision, a rare occurrence on a double-line section happened at 1.55 a.m. on 2"d August 1999, between two express trains Brahmaputra Mail and Avadh-Assam Express - at Gaisal (North Bengal) railway station. 278 passengers were killed including drivers and assistant drivers of both the trains. Over 500 were badly injured. A statutory inquiry into the cause of the accident by Chief Commissioner of Railway Safety, Mr. M Mani, was announced.

Some notable rail accidents are as under :

Date	Place	Fatality
25-06-90	Mogta, Bihar	60
05-09-92	Raigadh, MP	41
16-07-93	Darbhanga, Bihar	60
21-09-93	Chhabra, Raj.	71
14-05-95	Salem, TN	52
20-08-95	Firozabad, UP	302
18-04-96	Gorakhpur, UP	60
14-09-97	Madhya Pradesh	81
26-11-98	Ludihana	108
16-07-99	Matura	17
22-06-2001	Kozikode, Kerala	40
09-09-2002	Bihar, Rafiganj,	120
03-01-2003	Ghatamnagar, M'rashtra	21
15-05-2003	Punjab, Fire	38

All such accidents denote safety problems and call for preventive measures. The Federation of Railway Officers stated that the political leaders are extending railway services without worrying for safety. (News 27-9-97)

471 rail accidents during one year, 1998-1999, (1.5 accidents per day!) and 2000 rail accidents during 1993 to 1998 tell us the story of railway safety! Internationally accepted latest computerised Auxiliary Warning System (AWS) cannot be applied to a large network of 62000 km rail track in our country, said the Railway Board. This technology costs Rs. 1 crore per kilometre (News 9-8-99). More attention on human errors and good maintenance of prevailing safety system remains the only remedy. This is the abstract of some 2000 reports submitted to the Railway Ministry indicating 40% accidents due to human errors!

The retired SC Judge Shri H. R. Khanna, Chairman of Railway Safety Review Committee, submitted its report to the Railway .Board. This report outs stress on radio communication facilities, safety and warning systems, train actuated warning system, axle counters, flasher lights, emergency provisions in engines, modern track data recording system, reducing human element and increasing quality of training and education to all types of railway employees including drivers (News 30-8-99).

'Anti collusion device prepared by Konkan Railway will be fitted to all the trains', said the Railway Minister Shri Nitish Kumar (News 11-10-2001)

In an accident between a goods train and a passenger train at south Mozambique, 20(1 people died and 200 to 300 injured. Aeroplane bowing 747 burst into the sea near west seashore of Taiwan and all 225 passengers died: (News 26-5-02)

234 air-travellers died in a plane crash in Indonesia on 26-9-97. The great jungle fire in Indonesia caused a heavy loss of environment in hundreds of kilometres and for days together in September 1997.

Regarding urbanisation, Warner Foreno, the President of Population Institute at Washington, reported "the half of the world population lives in cities and towns" and it was also predicted that by the end of the year 2050, two-third of the world population would be found in cities. This will create urban problems. (News 31-12-2000)

Thus increasing industrialisation, urbanisation and transportation are causing accidents and dangers to human life. Fatal Road accidents' of 1995 occupy 34.02% of total fatal accidents of that year. Factory and machine accidents (fatal, 1995) were only 0.31%.

The Report of the **Indian National Commission of Labour** said in 1969:

"In a country as populous as ours, there can be danger of a tendency developing to discount the value of human life. Its loss in accidents or through the slow and agonising process of an occupational disease may not stir the community as much as it could be in countries with chronic labour shortages, though to the near ones it is a tragic occurrence. Relief gets organised after the event, but prevention gets side-tracked ".

This observation describes the accident problem and suggests the remedial measure that prevention should not be sidetracked. This emphasizes the concept of safety.

Effects of industrial sickness on safety:

The worldwide recession, globalisation and international quality competition may retard the industrialisation described so far. However, big chemical complexes may generate more and more opportunities for safety professionals. Small-scale units shall have limited scope. Due to globalisation, automation and computerization, the employment may not increase as per expectation.

The Labour Department of USA has declared that the unemployment rate has been increased to 6.4% in the last month. This is the highest unemployment rate of last 10 years. Many people are in search of jobs but they do not get employment. (News 11-07-2003)

Unemployment rate in Saudi Arabia is reached to 12% and therefore its Government decides to retrench 17800 foreign workers and has advised them to leave the country within one month. (News 18-07-03)

Planning Commission of India reports: 'Employment growth rate has been reduced from 2.00% to 0.98% during last six years'.

Observation of **National Sample Survey** says that 'When the GDP increased from 5.8% to 6.7% (industrial growth), the employment growth rate was decreased during 2001-02.

The employment growth rate of public sector was decreased from 0.10 to 0.03%.

At the end of the year 2002-03, in Gujarat, a figure of unemployed literate persons was about 9 lakhs (as per Employment Exchange Office) and this may become 40 lakhs in year 2010. (News 16-07-03)

Thus industrial and employment retardation, worldwide recession, financial hardship and effects of globalisation may retard the movement of safety in our country (News 22-5-2001).   .

Industrial production has been increased but employment opportunities have not been increased proportionately. Some 6 lakhs industries and factories have been closed down. As a result, lakhs of workers have become unemployed. The State of Kerala stands first in literacy rate but however the unemployment of literate people is also the highest in that state.

Comparing with the metro cities, unemployment in villages has been increased. Due to the ill effects of Government policy, condition of agriculture and small and cottage industry has been worsening. It has resulted in unemployment in villages too.

More and more workers from organised sector are being thrown in unorganized sector. Therefore, economic imbalance, people living below the poverty line and unemployment are continuously increasing. This is the sad scene. (News 11-6-03)

When industries become sick, manpower decreases, automation increases, the cost of everything goes on rising, trade union activity diminishes and Govt. policy not boosting the industry, how an employer will think of safety, a non-productive factor for him? When question of survival comes, many factors like employment, safety training, HRD, welfare and other facilities may go away and scenario will be of retarding from our important commitments toward safety. ILO conventions and recommendations, statutory provisions and legally awarded health and safety measures may remain on paper only.

Let us try to change this hazardous situation, reverse the retardation and try to prosper industry, employment, safety awareness and healthy atmosphere everywhere.

Let us hope, new industries will come, employment will increase and work of safety professionals will also increase.

4. DERIVATION OF THE CONCEPT OF SAFETY

Thus from the above discussion of struggles of –

1. Dead Vs. Live resources,
2. Health Vs. Wealth and
3. Industrialisation Vs. Accidents,

- and from the reply of following questions:

1. What are more important? Dead or Jive resources? A machine or its creator? A material or its user? Money or its beneficiary?
2. Should people die or meet with accidents in a race for wealth?
3. Should hazards and risks be ever increased with the growth of industries?

- What ultimately derived is the need, importance and fundamental understanding of the ***'Concept of Safety'*** only.

People want both-dead and live resources, health and wealth and industrialisation and employment - but nobody wants accidents. This becomes possible if and only if the concept of safety is understood and followed.

To maintain safety of people and to follow safe work practices in safe working conditions is the only way to prevent and control the hazards of environment (including industry). Therefore it is most important to realise, study and apply the concept of safety in every walk of life, particularly in industries.

Following this basic concept of safety, the concepts of total loss control, total loss prevention and hazard control technology have been developed. .Risk assessment, safety audit, various engineering, medical and administrative safety measures are developed and followed to implement this concept of safety.

Technology Advantages to be utilised:

It is this concept of safety only, which is worldwide controlling and trying to decrease accidents and injuries. Though the increasing trend of industrialisation to increase living standard of people, may increase risks, accidents and losses, yet the progress of the same science, technology, industrial hygiene, and engineering may, on the other hand, help to eliminate or control those hazards and therefore this second aspect of the Safety Technology should be fully utilized.

The science of safety engineering, control technology and techniques of modern management have been advanced as under.

Antidotes have been developed for protection against health hazards. Microwaves and laser technology have eliminated high frequency hazards.

Linear motor train running at 451 km/h by electro-dynamic levitating force, thrust SSC car running at 1223.28 km/h, generation of bio-gas (fuel) from rotten vegetable waste and use of its residual waste as a cattle-food, fuel-cell to convert petrol into hydrogen to reduce vehicular pollution, French technique to get a desired baby, human cloning by a somatic cell and genetic engineering (first clone female baby borne on 26-12-2002, 11:55 a.m. at Florida, USA), fully automatic eye function controlled camera (camcorder), digital mobile cell-phone, motorised electric toothbrush and a ship-cum-plane (wing-ship) which can swim on the sea and fly in the sky have been invented.

Tele-presence technology has been developed to remotely carry out surgical operation on a person flying in a plane or sailing in a ship. Early detection of breast cancer from the hair sampling (change in molecular structure) has now become possible. Telecomputing, telemedicine and tele-shopping systems have also been developed. Not only e-mail, inter-net or website but v-mail will also become older in course of time. Robotic controlled systems of atomic plants will now be controlled by a newly developed tele-manipulator system (News 24-8-99).

New inventions of 3D Sonography and Bio-diesel are also reported.

The landing of a robotic spacecraft from earth, Pathfinder, on 4-7-97, on the red planet Mars, the launching of IRS-ID (Indian Remote Sensing Satellite) into an 817-km polar sun-synchronous orbit by our fully indigenous rocket PSLV (Polar Satellite Launch Vehicle) on 29-9-97 from Shriharikota island, successfully test-firing of the anti-tank Nag missile, another indigenous development, on the same day,. from Chandipur in Orissa, launching of another Satellite INSET-2E by ISRO on 3-4-1999 and remote robotic surgery on human body have proved the success of science and miracle of safety engineering in overcoming hazards, their correct assessment and control.

News of replacement of highly toxic chemical pesticides by non-toxic bio-pesticides is a good march towards safety. Gujarat Krushi University has made, for the first time, large-scale recommendations in this direction. An abstract of nimb leaves, tobacco dust, biolep, spinosed, cow-urine etc. have been specified and submitted as a report to the State Assembly (News 13-3-03).

Smoke of cow dung and ghee remove air pollution. Three insects - Dhaliu, Bhamari and Papati - known by our farmers, are non-chemical bio-insects to kill harmful worms and eggs in the farms. (News 1-7-03)

By non-chemical farming, a farmer got 7 ton more crop of sugarcane per hectare with less expenditure (News 18-3-03).

The same ultra modern technology is to be utilised for safety also.

Safety efforts of improvement in safe design, safe operation, safe preventive and corrective maintenance, safer technology, safe equipment and instruments and safe disposal of wastes are giving positive results. Thus the implementation of concept of safety has been proved fruitful.

5. NATURE OF THE CONCEPT OF SAFETY

History of the Concept of Safety is very old. Though the word Industrial Safety can be said to begin with the 19th century as textile mills and other industries started in England after the year 1800 and establishment of Factory Inspectorate in 1833.

The Concept of Safety has the oldest history in our country and subsequent development in foreign countries. It is explained below.

5.1 Age-old Concept: Indian Origin:

We are proud of our old heritage as it supplies almost all origins in all walks of life. It requires efforts to search it. Our Vedas, Kamayan, Mahabharat, Shukraniti, Kautilya's Arthshastra (Rajniti), provide valuable advices on industrial matters, c`gLifr] ;kKoDy;] ukjn] euq] 'kqØ] dksfVY;] fo'odekZ] Hkh"efirkeg] nzks.k] etc. are the great Indian seers who had explained the Labour Code from time to time. Their advice was according to their prevailing time and putting more stress on duties rather than on rights.

The basic concept of safety for human protection is explained in Rugved (6-75-14) by the following sentence-

iqeku~ iqekal% ifjikrq fo'or% !

Let man protects man every where in the world.

It is also said: /keksZ j{kfr jf{kr % which means Dharma, a divine force to govern all people by self-discipline, will protect them who protect themselves. Thus it is the primary duty of all of us to protect ourselves. This is the foundation of safety philosophy. The same theme of protecting one another on the strength of Dhrama (righteous behaviour) is also explained by:

u jkT;a uSo jktk·lhr]
u n.M;ks u p nkf.Md % A
/kesZ.kSo iztk los
j{kfUr Le ijLije~ AA

What were the hazards of ancient time from which men were seeking protection from God is well stated by:

j{kkafl ;=ksxzfo"kk'o ukxk%
;=kj;ksnL;q cykfu ;= A

nkokuyks ;= rFkkfC/k e/;s
r=fLFkrka Roa ifjikfl fo'oe~ AA

O Mother Goddess, thou protect us from serpents having lethal poison on their tongues, powerful enemies and robbers, great fire, and depth of the sea by being there and surrounding the world.

People were advised to exert cgqtufgrk;] cgqtu lq[kk; and they were in fact loZHkwrfgrsjrk% A

u Roga dke;s jkT;a u LoxZ u iquHkZoe~ A
dke;s nq%[krlrkuka izkf.kukekfrZuk'kue~ AA

It is neither political power, nor heaven, nor even rebirth that I aspire for. My only aspiration is to relieve all affected beings from their pain or suffering.

The well-known Upnishad advice runs as -

losZfi lqf[ku% lUrq losZ lUrq fujke;k% A
losZ Hknzkf.k i';Urq ek df'pr~ nq[kekIuq;kr~ AA

Let all be happy and healthy. Let all achieve welfare and no one gets any unhappiness.

Happiness cannot be achieved without safety and good health. Therefore above stanza speaks of safety, health and welfare of all, which is also the modern concept of all the safety laws.

lgukSvor~] lgukS HkquDrq and lgoh;a djoko gS
also tell that let us come together, suffer together and work together. This prayer is always useful to keep us on the way of safety.

The definition of Hkjr by whose name this country named as Hkkjr (Bharat) is Hkj.kkr j{k.kkr p~ was called Hkjr because he was maintaining and protecting. Hkkjr means the country to maintain and protect her people. Thus very name of our country contains the concept of safely. The king was said father only because he was giving protection, provision, education and livelihood. This basic duty of modern State ensures the concept of safety and welfare.

One of the definitions of nation, as given by Yajurved (22-22), calls for ten components which also include warriors to protect the country, best and ample weapons, enough load carrying vehicles and healthy and prosperous life. This Vedic concept is nothing but the concept of safety, health and protection of lives.

The basic safety of 'prevention is better than cure' is well explained as follows:

fpUruh;k fg foinkeknkoso izfrfd;k A
u d`i[kuua ;qDra iznhIrs ofguk x`gs AA

The reaction (preparation) should be thought before an emergency arises. It is of no use to dig well when fire has already ignited the house.

How an accident can or cannot save human life, is interestingly explained by:

vjf{kra fr"Bfr nSojf{kre~
lqjf{kra nSogra fou';fr A
thoR;kukFkks·fi ous folftZr%
driz;Ruks·fi x`gs u thofr A

An unprotected is protected by fate. A well protected but hurt by fate may be ruined. A person lost in jungle and without any help may survive. A person making all efforts in his home and surrounding with doctors (having all helps) may die.

Kautilya's Arthshashtra :

¼dksVyh;e~ vFkZ'kkL=e~½ The age-old Kautilya (Vishnugupta Chanakya)'s Arthshashtra (economics) is a big volume of old Indian rules on economics, politics and sociology which covers many 'subjects on trade, business, industry, commerce, administration, law and order, justice, architecture, design, construction and winning t)f forts, town planning, army etc. in those days. It has 180 chapters and 6000 stanzas. It has been translated in many languages.

This volume talks of atom's size, weights and measure, metallurgy, mines, metal processes, wood, lather, and other processes, agriculture, weapons, cotton, wool and dyeing processes, medicine and surgery, protection from fire, water, diseases, animals, natural calamities and so many things in a systematic way. A few references are given below:

nSokU;"VkS egkHk;kfu A
vfXu:nda O;kf/knqZfHk{ka ewf"kd% A
O;kyk% likZ% j{kkalhfr A
rsH;ks tuina j{ksr~ A

'Fire, water, diseases, scarcity, rats, wild animals, serpents and demon are eight great dangers. To protect people from these is a duty of the king.' Kautilya has explained problems as well as solutions.

A king (ruler) is advised to protect the people from enemies, bad workers, traders, act of God, antisocial elements, thieves and robbers, poisons, and many other things.

He had described many fixed and movable machines ¼fLFkj;a=kf.k py;a=kf.k½ to be used 'in war. He had described the metallurgical processes on gold, silver, copper, alloy, stone, iron, diamond, jewel, salt, etc., with safety precautions.

General philosophy for protection is explained as follows:

vkRefu jf{krs loZ jf{kra Hkofr A

Protecting our self we can protect all.

n.MuhR;kek;RrekRej{k.ke~ A

Our self is protected by rules of punishment, i.e. n.Muhfr A

nSoa 'kkafrdeZ.kk izfr"ks)O;e~ A

Natural hazards should be prevented by good efforts.

ekuq"kh dk;Zfoifra dkS'kysu fofuokj;sr~ A

Manmade hazards should be removed byskill and intelligence.

'k=ksjfi fof'k";irs O;kf/k % A

A disease is worse than an enemy. Therefore it should be prevented at the earliest possible.

'kkL=iz;kstua rRon'kZue~ A
foKkunhisu lalkjHk;a fuorZrs AA

The purpose of any science or literature is to give real knowledge of the things. This indicates the purpose of safety science, 'which removes the apprehension of the world.

The basic intention of all such rRon'kZue~ (realisation of element) is for the benefit, subsistence and protection of the earth (i`fFkO;k ykHks ikyus p) and humanity.

Warning for working against environment or nature ¼izdfr½ f.k is also given by:

lzdfrdksi% loZdksis{;ks xfj;ku~ A

Anger or revolt by environment is the highest of all angers!

The best advice is given by following Words.

U Roga dke;s jkT;a] u LoxZa u iquHkZoe~ A
dke;s nq%[krIrkuke~] izkf.kukekfrZ uk'kue~ AA

I have no desire of any kingdom, haven or even salvation. I simply desire to remove affliction or suffering of people hurt by agony or pain.

This is the object of protecting others, the best of philosophy of safety.

5.2 Age-old Concept: Foreign Origin:

Safety being the human instinct and basic need of mankind, its origins are universal and found everywhere in the world, whether they are reported or not. In Chapter-33 of History of the Safety movement, chronological order of concept development is given. Only an excerpt is given below.

'Prevention is' better than cure', 'Health is wealth' and 'Sound mind in a sound body are old and universal safety concepts. 'An injury prevented is a beneficiation, an injury compensated-an apology' is also an old quotation.

Risks and life are inseparable. In order to survive, man has acquired through the ages, instinctive habits and reflexes to protect him from the more common hazards. A man picking up a hot stone instinctively drops it before serious injury occurs to his hand.

Safety and science -are also inseparable. History of safety begins with the history of science. A man of an ancient era accidentally invented 'fire' and its uses. Fire safety began since then. Protection of self and family from heat, cold, rain, wild animals and enemies is an age-old concept of safety. The homes of cliff dwellers, pyramids, ancient Chinese tapestries, Indian. swords, metallurgy, architecture, woodcraft, mathematics, chemistry and similar antiquities attest men's industry thousands years ago. Because of his desire 'for self-preservation and fear of injury, the concept of safety was existed in the earliest civilisation. But earlier efforts were personal and defensive. The modern concept of organised safety started with the machine age.

Plato (BC 427-347), Gutenbarg (Printing Press in 1456), James Watt (Steam Engine in 1765), Eli Whitney (Cotton Gin in 1793), Isaac Newton, Thomson, Robert Fulton (Steaul Ship, 1807), Stevenson (Railway Engine, 1814), Michael Faraday, Thomas Alva Edison (Electric Bulb, 1879) are some earlier notable scientists who laid foundation of the machine age.

The *Ebers Papyrus* and the *Edwin Smith Papyrus* dating from @ 3000 BC (found in 1862) are the first written document on health and safety. They discussed about injuries and treatments involving splints, dressings and ointments.

Babylonian code of Hammurabi @ 2000 BC describes, "If a man strikes another, he shall be responsible for the physician." It is a code of some 280 paragraphs and covers bodily injuries and workers' compensation laws.

In @ 1500 BC Ramses III hired physicians to care for **mine and quarry workers.**

In @ 400 BC, Hippocrates, known as the father of medicine, described tetanus; About 200 BC, the Greek poet and physician Nicander described the effects of **lead poisoning.**

About 200 BC (found in 1898) a wooden aircraft model (length 6" x wings 7") was made which is kept at the Museum of Antiquities, Cairo, Egypt. Right brothers made, a simple balloon in 1903 i.e. some 2100 years later. Bhagvan Ram's **'Pushpak Viman'** was an invention much earlier than that.

An electric **dry battery** made in Iraq some 200 BC is kept in a museum at Baghdad. An astronomical clock made in 65 BC was found in 1900. All this indicates age-old concept of science and safety.

From 100 BC to 2nd century, various Roman writers described the plague of Athens, the ill effects of their environment on mine workers and un-healthful effects of lead for water piping and wine containers.

In 7th century in Lombardy, King Rothari codified the existing laws in 388 chapters on principles of compensation for injury. This work continued in 11th century also. In 1473, Ulrich Ellenbag, an Austrian physician warned about hazards of metal burning. George Agricola's book, in 1561, described air venting in mines and use of gloves, leggings and masks. In 1567, Paracelsus, published an article 'On the Miners' Sickness and other Miners' Diseases' wherein he distinguished between acute and chronic poisoning. In the early part of the 18th century, Ramazzini published 'Discourse on the Diseases of Workers'. He added one more question to patients: "What is your occupation?" He is called the father of occupational medicine.

Spinning jenny, power loom and cotton gins were discovered in 1764, 1784 and 1792 respectively. Industrialisation (mass production, mills) started in Britain in 18th century and spread to the Continent and USA.

In 1804, President Thomas Jefferson delivered his safety message to Captain Merewether Lewis at the start of the expedition (1804-1806). He talked of danger, risk and safety of the people.

In England Government factory inspectorate was established in 1833, and 'Great Factory Act' was enacted in 1844 to provide fencing for mill gears and shafts.

In 1833, George Stephenson suggested use of a steam whistle on locomotives. In 1866, first National Board of Fire Underwriters organised. In 1881, first Indian Factories Act was introduced in India. In 1900, first safety periodical named Safety engineering (presently Safety Maintenance) was published.

In 1903 demands of industrial workers were considered in Russia. In 1913, National Safety Council was founded in USA. In 1914 first safety of life at sea convention held in London and in 1918 first Air Mail Service started. First World War (1914) and Second World War (1939) accelerated the industrialisation and the need of safety. In 1919 ILO was established at Geneva and in 1921 it set up a safety service.

US Census of 1900 showed 1750178 working children between 10 to 15 years. In 1867, Massachusetts had begun to use factory inspectors and 10 years later that passed a law regarding safeguarding of hazardous machinery.

The concept of safety was well explained by the President of USA before the National Conference on Industrial Safety as follows:

"The plain fact is that our Nation cannot afford the needless loss of skilled workers if we are to produce for prosperity in this country and for peace abroad."

5.3 The Concept Described:

The concept of safety has been developed as a basic need of human protection. It is obviously and essentially necessary to protect lives of human beings and all living creature from natural and manmade hazards and to prevent the property losses for an economic interest also.

For this purpose, the concept includes various methods of hazard detection, inspection, analysis, measurement, assessment and application of safety measures. It includes all aspects of accident prevention and control,, occupational health & hygiene and environmental protection (pollution control). In this context, it is a broader concept of international acceptance and most vital for our present life and the life of our future generation.

In spite of all efforts of prevention, accidents do happen and therefore the concept of safety includes all control measures to mitigate the aftereffects of any accident, injury, death or emergency. In this sense, the concept of safety is inclusive of all hazards and risk control techniques, research and application. It also includes safety information, education, training, supervision, public awareness and involvement programs and statutory measures necessary from time to time,

Therefore the concept of safety can be described as follows:

It is an age-old concept as well as always advancing. It is basic as well as specific. Basic concept means all basic, general, fundamental and primary safety rules, while specific concept includes specific safety knowledge to solve specific safety problems. The concept is technical, engineering, scientific, physiological, psychological, methodological, managerial, experimental, ergonomic, qualitative and quantitative. Its branches (area of work) are many. Industrial, space, road, rail, sea and home safety are the main branches. Mechanical, electrical, chemical, health and hygiene etc. are sub branches. Its coverage is very wide. It is not any single branch of science and technology but it includes branches of science, engineering, technology, health, hygiene, medicine, philosophy, psychology, management etc. It includes all statutory and non-statutory safety measures. It has, now, also developed as a separate specialised branch. Thus the concept is like a 'Diamond concept' having many facets. See figure 1.1

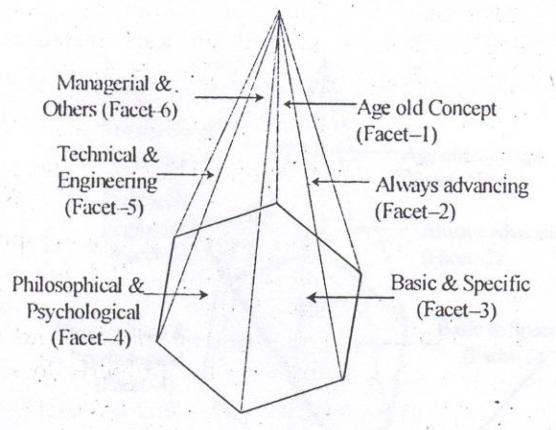

Fig. 1.1. Diamond Concept of Safety

The concept of safety is a broader concept and not limited to an accident prevention work only. In its true parlance, looking to the definition of environment the term Environment Safety includes occupational health and hygiene, pollution prevention and control, philosophy and psychology of safety, principles of management and all techniques of hazards detection, prevention and control technology, if hazards are prevented or controlled, risks will not arise, if risk is prevented, accident will not arise and if accident is, thus, prevented, accident is, thus, prevented; death, injury, damage and losses will not arise and that is the target of our concept of safety. If its engineering part is practiced from design to discharge level, less help will be required of its medical part. Production technology should be reinforced with the safety technology. If this much is understood, the concept is clear and to the point.

The concept of industrial safety began as *accident prevention*, widened as *Occupational health and hygiene* and gas reached up to the level of *Environmental protection*. But as the majority of the hazards are concentrated in industry, the term *industrial safety* is more prevalent. See figure 1.2

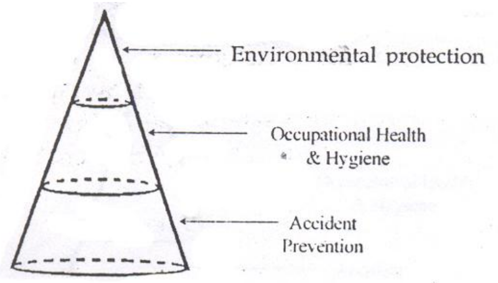

Fig 1.2. Three Stage Development of the Concept of Safety

Thus Industrial safety includes three things- accident prevention, Occupational health and Environment protection.

Industrial Safety can thus be defined to mean 'Protection of environment from hazards of an industrial activity.' Here 'environment' includes workers, public plant, property, land, air, water and their interrelationship. Industrial activity, includes storage, process, transport, transfer, use, handling or dealing with all materials (including raw materials, products and wastes), plants and machinery, land and building piping and equipment etc.

The concept of safety is philosophical because it is a way of thinking and searches for 'why' and how the root and the ultimate aim of safety. Philosophical of safety is explained in Chapter- 2

It is psychological, because it studies human behavior in much detail as a root cause of accident responsible resource for accident prevention and as a subject of safety. It keeps human as a centre for protecting from hazards. see figure 1.3 that is why the occupational safety is also termed as *Human engineering* psychology of safety is explained in chapter – 3

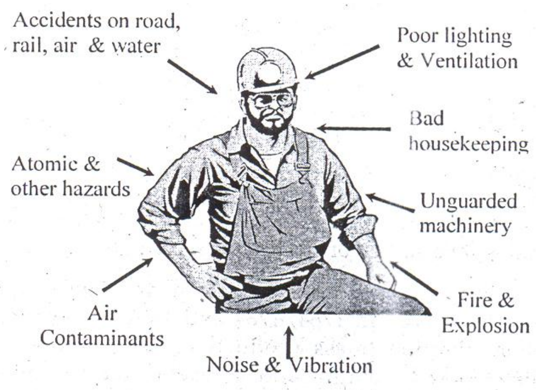

Fig. 1.3 : 'Man' is to be protected from Hazards

It is analytical, because it examines minutely the elements of accident occurrence and always tries to prevent its recurrence. The concept emphasizes on causation analysis and appropriate remedial measures based on that analysis. The accident causation and prevention is explained in Chapter- 4

It is quantitative, because, it insists for safety statistics costs of accident, budgeting, of safety, measurement of safety performance, safety limits, safety indices, values, marker, records and full data on all safety subjects. Statistics of Safety is explained in Chapter – 5

The concept of safety has also been developed as safety management systems. Many safety management programs have been developed. Safety department now occupies an important role in industry. Safety policy, safety committee, safety officer, safety training etc., are given due weight-age. The safety management is explained in Chapter – 6

The concept is universal i.e. equally important for all living creatures in the universe and includes all areas of activities everywhere. Therefore the concept of safety in a variety of subjects is subsequently explained in rest of the Chapter 7 to 33.

5.4 The Concept of SHE or HSE:

Above discussion of concept of safety in part 5.1 to 5.3 reveals that the word Safety has very old origin since centuries. The aspect of Health i.e. safety of health or safety from health hazards was added from 200 BC when the un-healthful effect of Lead poisoning was noticed. The last phase of **Environment** safety is added from the 20th century when the developed countries like UK & US first experienced the ill effect of environment pollution and the laws for the protection of environment were found necessary. In our country, the first law for water pollution control was enacted in 1974 and more laws were added since 1986 with the beginning of Environment (Protection) Act. 1986.

Thus the concept of safety does not remain limited to a narrow meaning of safety as accident prevention work from mechanical or machinery hazards only. As stated above, in course of time, it has included many aspects of safety from health hazards due to chemicals, other materials and their processes and safety from environmental hazards mainly due to pollution of land, water and air, thus the modern concept of safety has been developed as the concept of Safety, Heath and Environment i.e. SHE, HSE or EHS. Therefore in modern industries, the Safety Department is re-designated as 'SHE or HSE dept' and it carries our combined functions as under :

1. Main function of SHE Department is to plan. Execute and coordinate the specific function of Safety Manger, OHC Head or Factory Medical Officer and Environmental Manager

2. Function of Safety Manager and his office (subordinate safety officers and staff) are many but broadly they should include-
   a. Duties mentioned in Rule 6 and 7 of the Gujarat Safety Officer Duties, Qualifications and Conditions of Service Rules, 1983 (For details see Part 8.2 of Chapter – 6)
   b. Safety Managerial functions as explained in Part 6 to 12 of Chapter – 6 Such functions include plant visits and carrying out scheduled inspections and safety audits, meetings, including safety committee's meeting, accident-incident- near- miss investigation, HAZOP study, HAZAN, risk assessment, statutory compliance, development and updating of safety documents including SOPs, work permits, safety instructions for workers and public, training programmes, PPE and other safety equipment, rehearsal of emergency plan etc,

3. Function of Factory Medical Officer or OHC should include -
   a. Statutory medical examinations and reporting as mentioned in Gujarat Factories Rules, particularly in schedules u/r 102 and rule 68 R, T & U.
   b. First aid training for workers and
   c. Other training programs on industrial health and hygiene.

4. Functions of Environmental Manager and his office are day by day increasing due to enactment of more and more laws and guidelines issued from time to time from MoEF and GPCB/ CPCB. They include-
   a. Provision and maintenance of ETP and air pollution control devices to keep under control all pollution parameters prescribed by law and legal offices.
   b. Taking regular samples of water, air, stack and other emissions, noise level etc., to analyze them in laboratory, to record them in prescribed forms and to report to the authorities.
   c. Making arrangement of consultancy services if required.
   d. Arranging training programmes on environment safety.

Therefore now-a-days some companies require officers possessing combined qualification in safety and environment e.g. Post Diploma in Industrial Safety and also such diploma in environment to carry out above functions of SHE department.

6. NO EXCEPTION TO SAFETY

Thousand of examples and detailed discussion so far reveal that we have no exception to safety i.e. there is no substitute for safety, Results of undermining safety are very bad. One example can be cited as under:

Burning and breaking of space shuttle 'Colombia' of NASA and death of seven astronauts on 1-2-03 compelled accident inquiry. News report from New York disclosed that five members panel and two consultants were removed from the service who had earlier pointed out the safety problems in space shuttles and advised to increase the NASA budget for more safety measures. It was also reported that NASA had ignored the advices. Warnings and inspection remarks and long-term safety measures suggested by panel experts. The result was the death of seven young persons loss of 2000 crore dollars, space shuttle and other property loss of many million dollars! *Is it not a huge cost of undermining safety? Is it not eye opening and alarming for all of us to pay prompt and proper attention on all matters of safety? Let its do that.*

The present status of unsafe working conditions polluted environment and deteriorating health, explained earlier, make us unhappy and disappoint us for the future, if such status may continue.

Let us determine that we have to make our future safe and bright. We must remove or reduce all unsafe and unhealthy conditions from everywhere. If this should be the target. One thing is certain that there is no exception to safety. *The concept of safety and its strict adherence only will make our future bright and save the mankind.*

Let us determine to protect all people, working anywhere, by implementing the concept of safety through and by effective prevention and control measure.

SUMMARY:

Liver resources must be protected against the hazards of dead resources. The most important live resources is 'man' who is at the centre of all safety activities. His health is to be protected from the hazards of race for acquiring wealth and all ill effects of industrialization and accidents.

This basic need explains us the concept of safety and this concept is not new. It is age-old and universal accepted. It has many facets like diamond. It includes all branches of knowledge, which is useful to identify and prevent or control the hazards. In its wider meaning of 'environmental safety' it includes accident prevention, occupational health, hygiene and environmental protection. For this purpose, it includes all statutory and non-statutory safety measures.

It must be determined that there is no exception to safety.

E X E R C I S E

1. "Introduction to safety is incomplete without understanding the concept of safety". Explain this statement and discuss "The concept of safety as the basic philosophy of safety
2. Explain and derive the concept of safety.
3. Define 'Industrial Safety' and explain its meaning with examples.
4. **Explain the lessons of the following examples:**
    1. Glowing girls.
    2. Green-peace International Report.
    3. Dangers of pesticides.
    4. Spray-bottle in school bags.
    5. BARC repot.
    6. Down to Earth repot.
    7. Courts' orders on pollution control.
    8. Scandinavian Research report.
    9. WHO report on Air Pollution.
    10. The landing of *Pathfinder*.
    11. Atlanta Report.
    12. Ganga and Yamuna, both are polluted.
    13. Agenda Report of Central Labour Ministry.
    14. Falling of Colombia Space Shuttle.
    15. Hazards of Modern Leaving.
    16. Effects of Adulteration.
    17. Polluted Air and Water.
    18. Pesticides Poisoning.
    19. Dangers of Cold Drinks.
    20. Technology Advantages.

CHAPTER – 2

Philosophy of Safety

THEME

What is stated in Chapter -1 about the Concept of Safety falls within the scope of philosophy of safety which we will see, now, in further detail.

1 WHAT IS PHILOSOPHY?

Philosophy is originally an Indian branch of knowledge. It had existence in our country before the English work 'philosophy' came into the existence.

Thousand years ago our profound Rushies and great thinkers told about rRo (element) and search for its rRoKku (knowledge), and this rRoKku is our oldest and current synonym for the English word 'philosophy'. It has its origin in Vedas, Smruties, Upnishads, Ramayana, Shrimat Bhagwat and other Purans, Mahabharat, Gita and many old and modern Indian literatures. Gita explains it as follows:

rf}f} izf.kikrsu] ifjiz'usu lso;kA
mins{;fUr rs Kkua] KkfuuLrRonf'kZu% AA

know that knowledge by leaning down, interrogating and serving to the philosophers who will teach you that knowledge.

Our concept of philosophy is a branch of knowledge searching for basic elements, origin, source, causation, effect reality and means to achieve and apply them to various fields. It includes science, which is a specific branch of knowledge having some characteristics like verifiability by experiments, definiteness, objectivity, certainty, predictability etc.

The philosophy is older and wider than the wide science, as it is in existence since centuries and has wide coverage of knowledge of all branches including that of science also. To study the nature and origin of science, its branches, utility, applications etc. is philosophy. It also studies art, sculpture, /keZ (which has no synonym in English and which does not mean religion), psychology, history of universe and its cause and effect.

Our old concept of philosophy was more concerned with /keZ] v/;kRe] search of God, universe, its elements, realities, causes and effects. As the scientific rules were invented gradually, science ¼foKku½ was separated as a special branch of philosophy.

The western concepts of philosophy are defined by Plato, Aristotle, Hegal, Bredle, Comte, Bartrand Russell, Dr. Brod, Kent, Fichte, Democratic, Marx, Burgsan etc. They have also explained the philosophy of science and the difference between the philosophy and science Their concepts are criticized and counter argued by other philosophers. Their views in brief are as follows:

Philosophy is a study of true realities and of appearances. It is the super science. It analyses and examines original or fundamental concepts of science or assumptions. It coordinates the scientific results with religions and moral experience of man. It studies the language and meanings. It visualizes or assesses the knowledge, its root, measure and limitations.

Philosophy has three original branches:

1. **Ontology searching** the root cause or fundamental element(s) in the creation of world.
2. **Cosmology** searching how this visible world is developed from the final element.
3. **Epistemology** discussing the forms, types, tests and limitations of the knowledge.

There are three conceptions about philosophy of science.

1. Its purpose is to think about the line of thinking and logic of science, and
2. Its function is to coordinate various kinds of knowledge, and
3. Its specific work is to analyse the methodology and problems of science.

Major problems of philosophy of science are the problems of reductionism, technology explanation, causation and induction.

Difference between Science and Philosophy

The science has specific subjects and divisions, it rest upon experience, observation, experiment and examinations, its rules are universal, unaltered and unchangeable. It has no two opposite statements or opinions and it does not recognize religion.

The philosophy has no specific subject, it interprets facts and findings, it searcherfor common principles lying at the root of facts, it finds generality of totality, it does not need experience or experiment, though it recognizes them, its attitude is intellectual and logical, it includes theories of opposite opinions also viz. reality and ideology, spiritualism and materialism, }Sr & v}Sr] ukfLrd & vkfLrd theistic and atheistic, free behaviour and morality etc. it recognizes the religion and always looks for the final truth.

2 PHILOSOPHY OF SAFETY

After understanding the nature of philosophy in general, let us be precise over the philosophy of safety.

2.1 Need of Safety Philosophy :

The objectives of philosophy of safety are to –

1. Think about what is safety, what is its need, where it is required, what are its types and applications etc.

2. Protect and serve the mankind, to search, suggest and apply
   (a) the safe ways of behaviour (action)
   (b) the safe working conditions and
   (c) the safe environment for the safety, health and welfare of all people.

This shows the highest importance of the subject of safety, as it has started form the age-old need of need forever. This is the superme significance of the philosophy of safety.

2.2 Nature and Subjects of Safety Philosopy:

Safety is directly connected with science, technology, engineering, health, hygiene, toxicology, psychology, management and law specific rules or principles on specific safety subjects. The philosophy of safety tries to search and coordinate the common causes and remedial measures for general as well as specific safety problems. It begins with the basic need or requirement of safety, its fundamentals, causation analysis and consequence, methods of detection of unsafe condition, unsafe action and reason and sequence of accident occurrence. It searches for the principles and methods of accident prevention and speedy control after the happening, safety devices, fittings, techniques and measures, factors impeding and approving safety, safety responsibility and roles of various agencies: terminology, theories and mysteries of accident causation, prevention and control. It studies for physical, physiological, psychological and other factors affecting and strengthening safety. It studies costs and types of accidents and their significance, type of safety management necessary and ways and means of providing and maintaining safe working conditions and human actions affecting health and safety of people and the safety of environment. It touches the origin, development and amendment of safety law and its innovation and all safety needs in the areas of industrial and environmental safety including safety at home, road, rail, water and air. Thus the field of safety philosophy is unlimited, its scope is very wide to include the entire subjects of safety from origin to the research, the latest development and form causation and behavioural analysis to the modern concept of design, testing, reliability, hazard control techonolgy, risk analysis, assessment and audit, emergency planning, public awareness and involvement programmes and all future developments.

3 SAFETY TERMINOLOGY

Like other branches of science, many words and terms are now well defined in safety science. Some terms are defined by statutes from legal point of view. Some commonly used safety terminology is given below. It is most important to understand these words as they clarify many concepts of safety philosophy, safety science and safety law. Other terms are defined in respective chapters. For terminology of MSDS, see part 7.2 of Chapter – 18. For terminology of Risk Management see Part 4.3 of Chapter – 19.

3.1 Accident:

An accident is defined in different ways

Dictionary meaning of ‘accident’ is an unexpected event or mishap. It is defined as an event that is not expected, intended or imagined. It refers the event not the result or effect.

An accident is an unplanned event that interrupts the completion of an activity and that may (or may not) cause damage to person, property or environment.

Unintentional injury is the preferred term for accidental injury in the public health community. It refers to the result of an accident.

An accident is unintended, unplanned event or its sequence caused by unsafe condition(s) or/and unsafe act(s) and may result in immediate or delayed undesirable effects.

An accident is an unplanned and uncontrolled event in which the action or reaction of an object, substance, person, or radiation results in personal injury or the probability thereof.

It is also defined as an unexpected, unintended or unforeseen event that causes injury, loss or damage.

An accident is any unplanned, sudden event, which causes or is liable to cause or is liable to cause an injury to man materials (including plant) or environment.

An accident is any occurrence that interrupts or interferes with the orderly progress of the activity which causes or likely to cause injury with or without damage to property or environment.

An accident is the result of carelessness, casualness or any fault known or unknown.

An accident is an unwanted transfer of energy beyond the threshold limits. In case of accident to a person, physiological energy loss is an accident while in other cases it may be an energy loss from material.

It is an event, which is unexpected, unavoidable, unintentional act resulting from the interaction of host (accident victim), agent (injury deliverer) and environmental factors within situations, without involve risk taking and perception of danger – *Suchman.*

An accident is an unexpected, unplanned event which has a probability of causing personal injury or property damage or both. It may result in physical harm (injury or disease) to person(s), damage to property, loss to the company, a near miss or any combination of these effects including delayed effect.

An accident is an unexpected, unplanned event in a sequence of events, that occurs through a combination of causes, it results in physical harm (injury or disease) to an individual, damage to property, equipment, building etc., a near miss, loss to the company, or any combination of these effects.

An accident is an unplanned, not necessarily injurious or damaging event that interrupts the completion of an activity. It is invariably preceded by an unsafe act or an unsa fe condition or their combination.

An industrial (occupational) accident is also defined a san undesirable event that result in a certain length of disability and stoppage of work and time loss due to the effect of a production-related dangerous factor or a combination of such factors.

An occupational accident is presently regarded as an index or a symptom of dysfunction in a system formed by a production unit, such as a factory, a workshop, a shift or a workplace.

Occupational accident is also defined as "any organic or functional injury or damage to body, limbs or health or psychic disorder due to an external, sudden or violent cause occurring during work or due to work itself and resulting in death or total or partial, permanent or temporary incapac ity for work" Fata accident or death from accident is an accident that results in one or more deaths within one year from the date of accident.

Philosophy of accident: it should be noted from above definitions of 'accident' that-

1. In accident phenomenon, which includes event and its effect, 'event' is more important then its 'event' Event or consequence may or may not be there. For example, a person getting chemical splash (exposure), struck by falling body, falling by striking against object, falling from height, getting electric shock or meeting with road accident may not get any injury or his normal activity may not be interrupted. Here event has taken place but it has not a notable effect. Even then this is an accident for the purpose of finding the 'cause' of event and remedial measures to prevent its recurrence.

2. Event may be one or more. One thing falls or may things fall one by one, only fire takes place or explosion follows the fire, events of primary and secondary explosion, collision of many vehicles, one persons die or more persons die in a sequence or due to different injuries in one accident may constitute one accident.

3. Idea of 'accident by chance' is not acceptable in safety philosophy. Each accident has its 'cause' or 'cause' that need inquiry, investigation and efforts to remove them. Considering accident as chance or fate does not help to prevent the accident and may result in another accident. Event if it is considered as chance, the 'causes' of that chance occurrence are important.

4. There may not be immediacy between event and effect. For example, pain or symptom may appear after repeated actions or few hours or days after the accident, cancer may occur after years from the exposure of a toxic substance. This delay or latency period' hides the effect for some time. However such accident of delayed effect may prove most serious and needs thought investigation and effective control measures viz. pesticide poisoning and control.

5. Duration or span of event may be short or long Span of event should be considered from its beginning to the end of the effect or consequence. Therefore when effect occurs just after the event begins, duration of event is short and when effect occurs after a long time (i.e. delayed effect) form the beginning of the event duration of the event is long. Therefore in definition of accident, immediate or delayed, both the effects are included. Chronic disease (effect) requires events of long duration.

   Legal definition of 'non fatal injury accident' or 'dangerous occurrence' makes it reportable after the duration of 48 hours from the time of accident. Thus legal definition of accident has considered 48 hours duration of event to notice any harmful effect. Accident causing death or possibility of death is to be reported immediately (Sec. 88 & 88A, the Factories Act).

   See Chapter-4 for further details about 'accident' its causation and causation and prevention and Chapters-28 & 29 for legal definitions.

3.2 Accident Consequence Analysis:

Consequence means effect or result of a specific event.

Accident Consequence Analysis is an analysis of the expected effects of an accident, independent of frequency and probability.

Mostly this is carried out after the completion of Risk Assessment to predict the consequences i.e. severity of the effects due to the assumed worst or maximum credible accident scenarios. See part 3.100.

With accident consequence analysis, the Vulnerability Analysis may be carried out of the persons, property and environment adversely affected.

Computer software is useful in carrying out consequence analysis and vulnerability analysis.

In such type of analysis, determination of following things is important –

1. Type of substance being released e.g. gas, liquid or liquid with vapour etc.
2. Type of release i.e. instantaneous, continuous, intermittent etc.
3. Leak rate or outflow volume and rate of evaporation in case of liquid pool

4. Dispersion calculation of the released mass. Parameters of atmospheric conditions are considered e.g. wind speed, weather condition (stability class) cloudiness, terrain conditions and sinking mechanism and absorption (influence of tree, houses etc. as obstruction of toxic gases.)
5. Damage distances i.e. damaging concentration or effect of fire or explosion at different distances in the direction of wind or other showing these distances and effects.
6. Severity of the effect i.e. vulnerability in terms of possible deaths, injuries, destruction of building or damage to environment. Use of probit equation.
7. Plotting of 'risk counters' on the area map of place of release and vicinity. Counters should indicate low, medium and high risk areas.

3.3 Accident Prevention :

Accident prevention is both science and art. It represents, above all other things, control i.e. the control of human performance, machine or equipment performance and physical environment.

The word 'control' connotes prevention as well as correction of unsafe conditions and actions. Prevention is the first step of control.

To control unsafe human actions, knowledge of psychology, philosophy and management are necessary. To control unsafe conditions, knowledge of engineering, health effects, industrial hygiene, ergonomics etc. are necessary.

Accident prevention requires five steps organisation, fact-finding analysis if the facts found, selection of remedy and application of the remedy. Sixth step of monitoring should be considered. It includes measurement of result, assessment i.e. comparing with legal criteria or standard, feedback and further improvement if necessary. See Chapter-4 for details.

3.4 Air Pollution:

In short it means contamination of air by harmful substances like toxic gas, dust, vapour, acid fumes, flue gases fuel gases etc. when it exceeds legal permissible limit, it is considered legally harmful.

In its broad meaning it includes detection, monitoring and chemical analysis of air pollutants, air pollution control equipment and engineering measurements and standards of industrial and automotive emissions and common air quality parameters, odours, acid rains, thermal discharge, gas and particulate emission, climate change, greenhouse effect, ozone depletion, chemical and biological aspects of air pollution, radioactive fall out radiation levels and their effects of air pollutants on soil, plants and animals.

3.5 APELL:

It means 'Awareness and Preparedness for Emergencies at Local Level'. It is a co-operative programme of the United Nations Environment Programme (UNEP), Industry and Environment Office prepared in june 1987, and was started in late 1988.

APELL's main goals are to prevent technological accidents (disasters) and, failing this, to minimize their impacts. This is achieved by assisting decision-makers and technical personnel to increase community awareness of hazardous installations and to prepare coordinated response plans involving industry, government and the local community, in case unexpected events at these installations should endanger life, property or the environment.

Thus APELL consist two parts (1) Provision of information to the community, which is called 'Community Awareness' and (2) Formulation of a plan to protect the public, which is called 'Emergency Response'. (On-site and off-site Emergency plans are legally suggested).

3.6 Care and Types of Care:

Reasonable care is that degree of care exercised by prudent man observance of his legal duties toward others.

Every person has a legal duty to exercise *due care* for the safety of others and to avoid injury to others if possible. Common carriers must exercise *great care.*

Responsible care is the safety duty towards society. Now this has developed as a systematic approach.

Responsible care is a chemical industry initiative, which started in Canada in the late in the late 1970s and is slowly gaining worldwide momentum: it is voluntary and the willing company has to demonstrate its commitment to improve all aspects of performance relating to safety, health & environment. This helps, in turn, to develop and maintain public acceptability of that industry

In India, ICMA (Indian Chemical Manufacturers' Association) has adopted six codes of management practices fro responsible care as under:

1. The Process Safety Code.
2. The Employee Health & Safety Code.
3. The Pollution prevention Code.
4. The Community Awareness & Emergency Response Code.
5. The Distribution Code, and The Product Stewardship Code.

3.7 CASH:

This means Change Agents for Safety & Health. This is a term used for Occupational Health and Safety program where different agents like noise, dust, heat stress, injures, chemical exposures, PPE, light, ventilation etc are considered as targets (.agents) for necessary change to get desired improvement at the work place.

3.8 Chemical Accident:

As defined u/r 2(a) of the Chemical Accidents (Emergency Planning, Preparedness, and Response) Rules, 1996, it means an accident involving a fortuitous or sudden or unintended occurrence while handling any hazardous chemicals .[defined in rule 2(b)] resulting in continuous, intermittent or repeated exposure to death or injury to any person or damage to any property but does not include an accident by reason only of war or radioactivity.

3.9 Chemical Safety:

It means 'safety' from hazards of chemical. See definition of 'safety' at Sr. No. 3.80 following.

3.10 Code of Practice:

It is a document offering practical guidance on the policy, standard-setting and practice in occupational and general public safety and health for use by governments, employers and workers in order to promote safety and health at the national level and at the level of the installation. A code of practice is not necessarily a substitute for existing national legislation, regulations and safety standards.

3.11 Confined Space:

Confined space as defined in clause (o) of Part1, Schedule-19, Rule-102, Gujarat Factories Rules, means any space by reason of its construction as well &s in relation to the nature of the work carried therein and where hazards to the persons entering into working inside exist or are likely to develop during working.

Normally a confined space is enclosed from all sides except one for entering inside and coming out from the same e.g. manhole or open top. It is not a normal place for working. Inside risks include possibility of toxic gas or dust, oxygen deficiency, fire, explosion, high temperature, sudden flow or pressure, accidental starting of stirrer etc., burying (engulfment) under free flowing solid e.g. grain, cement, sugar, drowning in liquid at bottom and similar causes.

NIOSH, USA describes 'confined space' as a space which has any one of the following characteristics:

1. Limited opening for entry and exit.
2. Unfavourable natural ventilation, or
3. Not designated for continuous worker occupancy.

Confined space is also classified as that –

- has vertical or maze exit, or
- contains loose dust, fluidised materials or unstable solids.

Examples of confined spaces are - tank, pit, sump, vat, duct, gutter, tunnel, sewer, drain, trench, pipe, reaction vessel, boiler, chimney, flue, furnace, oven, ceiling voids, enclosed room/basement etc.

Proper safety work permit, work place monitoring, use of self breathing apparatus and safety belt, rescuer standing outside and holding life line are the important **safety measures.**

See Part 2.1 of Chapter 16 also.

3.12 COSHH:

It means 'Control Of Substances Hazardous to Health' Regulations 1994, published by the Health and Safety Executive (HSE), UK. It is a guideline, not compulsory but helpful. Its compliance requires -

1. Assessing the risks to health arising from the work.
2. Deciding what precautions are needed.
3. Preventing or controlling exposures.
4. Ensuring that control measures are used and maintained.
5. Monitoring exposures of workers to hazardous substances and carrying out appropriate health surveillance, and
6. Ensuring that employees are properly informed, trained and supervised.

3.13 Damage Control:

It is directly concerned with the protection of machinery, materials and manufactured goods assets from accidental loss within the factory. Indirectly it is concerned with money asset and manpower asset.

Damage can be defined as severity of injury or the physical, functional or monetary loss that could result if control of a hazard is lost.

3.14 Danger:

It expresses degree of exposure to a hazard. By taking suitable precautions, the danger is reduced. Machine guarding or safety device reduces the danger of a particular hazard.

3.15 Dangerous Occurrences:

Dangerous occurrences are mentioned u/s 88-A, of the Factories Act 1948 and u/r 103 of the Gujarat Factories Rules 1963. They' include:

1. Bursting of a steam plant under pressure.
2. Collapse or failure of lifting appliances or overturning of a crane.
3. Fire, explosion, escape of molten metal, hot liquor, gas etc.
4. Explosion of a pressure vessel.
5. Collapse or subsidence of a structure. For Dangerous Chemical Reaction see Part 3.39.

3.16 Disaster:

Disaster is a catastrophic situation in which the day-to-day patterns of life are, in many instances, suddenly disrupted and people are plunged into helplessness and suffering and as a result need protection, clothing, shelter, medical and social care and other necessities of life, such as-

1. Disasters resulting from natural phenomena like earthquakes, volcanic eruptions, storm, surges, cyclones, tropical storms, floods, landslides, forest fires .and massive insect infestation. Also in this group, violent draught, which will cause a creeping disaster leading to famine, disease and death must be included.

2. Second group includes disastrous events occasioned by man, or by man's impact upon the environment, such as armed conflict, industrial accidents, factory fires, explosions and escape of toxic gases or chemical substances, river pollution, mining or other structural collapses, air, sea, rail and road transport accidents, aircraft crashes, collisions of vehicles carrying inflammable liquids, oil spills at sea, and dam failures.

3.17 Disaster Management Plan (DMP):

This is the requirement of Government Dept. (MoEF, GPCB, Factory Inspectorate, Collectorate etc.) under various Acts and Rules.

It includes On-site emergency plan and Off-site emergency plan. Its key elements are

1. **Basis of the plan or risk assessment.** Hazards and emergency situations are determined with their possible effects. Typical scenarios and consequences are outlined for the purpose of offsite emergency plan (see part 3.2).

2. **Accident prevention procedures and control measures.** Organisational set-up and division of responsibility. It includes listing of control measures provided in the factory and to be managed from outside if not available in the factory. Help from outside agencies.

3. **Emergency response procedures.** It includes emergency control centre, communication system and description of roles to be played by plant people and outside agencies.

4. **Recovery procedures.** It includes safe shutdown or flow restriction procedure, evacuation and restoring of normal condition.

See Part - 7 of Chapter - 19 for details.

3.18 Ecology:

It includes interaction between microbes, plants and animals and their environment, which are primarily affected by climate, water resources, soil and man, ecosystem studies, ecology of grasslands, woodlands and wetlands, arid zones and high altitude environments, coastal ecosystem, mangroves, aquatic ecosystem, fresh waiter, river basins, brackish water, marine, estuarine and soil ecology.

3.19 Emergency:

Emergency could be defined as any situation, which presents a threat to safety of person or/and property. It may require outside help also.

As defined in clause 2(j) of Schedule 19 of Chemical Works u/r 102 of the Gujarat Factories Rules (GFR), emergency means a situation leading to a circumstance or set of circumstances in which there is a danger to the life or health of persons or which could result in big fire or explosion or pollution to the work and outside environment, affecting the workers or neighbourhood in a serious manner, demanding immediate action.

It is also defined as, 'a dynamic incident in which there is continuing potential for major injury, ill health, damage to property, to the process or to the environment.'

3.20 Emergency Plan:

Emergency plan is a formal written plan, which on the basis of identified potential hazards at the installation together with their consequences, describes how such hazards and their consequences should be handled either on-site or off-site. See DMP at Sr. No. 3.17.

See Part 7 of Chapter - 19 for details.

3.21 Emergency Services:

Emergency services mean external bodies which are available to handle major accidents and their consequences both on-site and off-site, e.g. fire authorities, police, health services etc.

3.22 Environment:

As defined u/s 2(a) of the Environment (Protection) Act, 1986, it includes water, air, land and the inter relationship which exists among and between water, air and land, and human beings, other living creatures, plants, micro-organisms and property.

3.23 Environmental Management:

In its broad meaning it includes Government policies, planning, programmes, regulations and legislations, international agreements, environmental impact assessments(EIA), environmental education, environmental law and legal actions, sustainable development, siting of industries, clean technologies, eco-development and ecosystem management, managerial aspects of forestry, biosphere, conservation, waste and wildlife.

3.24 Environment Management Plan (EMP):

After identification and assessment of adverse impacts on environment due to proposed activity of a new plant or expansion of existing plant and after preparation of Environment Impact Assessment (EIA) document. Environment Management Plan (EMP) becomes necessary.

The EMP describes general good practice measures and site-specific measures to mitigate potential impacts due to the proposed industrial activities. The EMP provides mechanism to address potential adverse impacts, to instruct contractors and to introduce standards of good practice to be adopted for all project works.

For each stage of the programme, the EMP suggests effective mitigation of every potential biophysical and socio-economic impact identified in the EIA. It presents following information:

1. A list of mitigation measures.
2. Parameters to be monitored to ensure effective implementation of the action.
3. Time schedule to implement actions to ensure that the objectives are fully met.

3.25 Environmental Pollutant:

Defined u/s 2(b) of the Environment (Protection) Act 1986, it means any solid, liquid or gaseous substance present in such concentration as may be, or tend to be, injurious to environment.

Environmental Pollution means the presence of environmental pollutant in environment.

3.26 Error:

Errors are of different types, viz. human error, design error; planning, production, operation and maintenance error etc.

Human error can be defined as a human's action, which differs from or is inconsistent with prescribed or established behaviours or procedures. It may be of two types: predictable or random.

Predictable error occurs under similar conditions and can be foreseen because it has occurred more than once.

Random error is non-predictable and unique in nature. For example, all of a sudden a fly or insect enters in eye due to which a worker may throw away a tool or lose his balance and cause error. But if flies become common phenomena i.e. predictable, the error becomes predictable one and remedial measures are required.

Human error takes place due to omission (failure to perform a required function) or commission (performing a function not required), failure to recognise hazard, poor response, poor timing, wrong decision, sudden disturbance etc.

3.27 Evacuation:

It means to move all people from a threatened area to a safer area. It is required as a function of Onsite or Offsite Emergency Plan.

3.28 Fire Prevention and Control:

It is a special aspect of damage control. It protects machinery, materials, manufactured goods, money assets and manpower from damage due to fire.

See Chapter - 13 for details. -

3.29 Flash fire and Jet fire:

A flash fire is the non-explosive combustion of a vapour cloud resulting from a release of flammable material into the open and which after mixing with air, ignites. A flash fire results from the ignition of a released flammable cloud in which there is essentially no increase in combustion rate. The ignition source could be electric spark, a hot surface and friction between moving parts of a machine or an open fire.

Thus flash fire means a release of flammable gas under unconfined condition in the presence of air and ignition source. Dispersion process occurs between LEL and UEL with no increase in combustion rate.

A jet fire occurs when flammable gas releases from the pipeline (or hole) and the released gas ignites immediately. Damage distance depends on the operating pressure and the diameter of the hole or opening flow rate.

3.30 Foresee-ability:

A man may be held liable for actions that result in injury or damage only when he was able to foresee dangers and risks that could be reasonably anticipated.

3.31 Forestry:

It includes afforestation, including social forestry and energy plantation, deforestation, ecology and management of forests, influence of forest on the physical environment, protection of forests, soil conservation and erosion of forests, watershed / catchments management, endangered and threatened plant species.

3.32 Handling of a Substance:

As defined u/s 2(d) of the Environment (Protection) Act, it means the manufacture, processing, treatment, package, storage, transportation, use, collection, destruction, conversion, offering for sale, transfer or the like of such substance.

3.33 Harmful Element:

It means a substance, which in contact with the human body is likely to cause, during employment and long after, identifiable by modern methods, injuries and diseases or likely damage to the health of the present and future generations. Harmful elements may be injurious, toxic, corrosive or irritating.

3.34 Hazards:

Hazard means existing unsafe condition or action or situation or event or their combination which has potential to cause accident. Thus hazard can become a cause of accident or risk and it can exist without accident or risk. When due to hazard, accident happens, it is converted into accident. If hazard still exists, accident may happen again, viz. flammable atmosphere.

The causes of accidents generally remain latent for some time before anaccident occurs. These latent or potential causes are hazards. Hazards are sometimes referred to synonymously with accident causes, but there is a clear distinction that a. hazard can exist without an accident whereas an accident cause without an accident is an absurdity. Hazard recognition, diagnosis and elimination are essential to any successful safety programme.

Hazard is an inherent property of a substance, agent, a source of energy or situation having the potential of causing undesirable consequences.

Hazard means an intrinsic capacity associated with an agent or process capable of causing harm.

Hazard is defined as, 'any event with the potential to cause harm, ill health, injury, damage to property, plant, products or the environment, production losses or increased liabilities.'

Hazard is a condition with the potential of causing injury to personnel, damage to equipment or structures, loss of material, or lessening of the ability to perform a prescribed function. When hazard is present, the possibility exists of these adverse effects occurring.

Chemical Hazard is a hazard due to chemical (including its property, storage, process, handling, effect etc.) and it is realised by fire, explosion, toxicity, corrosion, radiation etc.

Major Hazard is a large-scale chemical hazard, especially one, which may be realised through an acute even.

For Major Accident Hazard (MAH) see part 3.55 following.

Occupational hazards are the hazards arising in course of and out of occupation or employment. They include physical, chemical, biological, mechanical, electrical, psychological and all occupational health hazards, diseases and poisoning.

Rapid ranking method is a means of classifying the hazards of separate elements of plant within an industrial complex, to enable areas for priority attention to be quickly established.

3.35 Hazards Analysis:

In simple term, hazard analysis means classification of hazards, eg. chemical hazards, mechanical hazards, electrical hazards, fall hazards, day and night wise hazards etc. in this way it is qualitative analysis.

Hazard Analysis is (i) Analysis of mechanism of hazard occurrence and (ii) Analysis of terminal consequences of hazards which may include number of injury, fatality, property damage and other loses. In this way it is quantitative analysis. Its study is known as HAZAN (Hazard Analysis). It means identification of undesired events, which lead to the materialization of a hazard, analysis of the mechanism by which such .undesired events could occur, and estimation of the extent, magnitude and likelihood of any harmful effects or consequences.

Preliminary Hazard Analysis (PHA) is a procedure for identifying hazards early in the design phase of project before the final design has been established. Its purpose is to identify opportunities for design modifications, which would reduce or eliminate hazards, mitigate the consequences of accidents or both.

HAZAN (Hazard analysis) is generally undertaken at the preliminary stage of determining the location, basic design principles and operational parameters to establish the adequacy of basic safety of design, operation and environmental control. It may be followed by an updated analysis to establish final risk levels. HAZAN exercise has to be undertaken by a professional team with expertise in failure mode and effect analysis, fault tree analysis, simulation and modelling, event tree and consequence analyses.

3.36 Hazard Assessment and Survey:

Hazard assessment is an evaluation of the results of a hazard analysis including judgments as to their acceptability and, as a guide, comparison with relevant codes, standards, laws and policies.

Hazard survey means the total efforts involved in an assessment of the hazards from installations and their means of control.

3.37 Hazard Identification:

It is an identification of sources of hazards and their causes. It is qualitative. Its study is known as HAZOP study.

Many methods and techniques are available to identify hazards. See Chapter -19.

In simple term, it means listing of unsafe conditions, actions, situation etc.

Hazard identification is the first and important step. If hazards are identified and removed, risks are prevented. If risks are prevented, accidents are prevented. If accidents are prevented, injuries and losses are prevented and that is the object of safety.

3.38 Hazardous chemical:

Hazardous chemical is defined u/s 2(e) of the Manufacture, Storage and Import of Hazardous Chemicals Rules, 1989 as a listed chemical in Schedule 1, 2 and 3 therein. The same term is also similarly defined u/r 2(b) of the Chemical Accidents (Emergency Planning Preparedness and Response) Rules 1996 and u/r 68J(1)(a) of the Gujarat Factories Rules, 1963.

When threshold quantity of hazardous chemical listed in Sch. 2 or 3 exceeds in a plant it is identified or classified as a Major Accident Hazard (MAH) installation. See Part 3.55 also.

3.39 Hazardous Substance, Process and Reaction:

Hazardous substance is defined u/s 2(e) of the Environment (Protection) Act 1986, as a substance or preparation which, by reason of its chemical or physico-chemical properties or handling, is liable to cause harm to human beings, other living creatures, plants, micro-organism, property or the environment.

It is an element, compound, mixture or preparation, which by virtue of chemical, physical or (eco) toxicological properties constitutes a hazard.

Toxic Substances as defined in clause (i), Schedule 19 on Chemical Works u/r 102 of the Gujarat Factories Rules, mean those substances which cause fatality or serious health effect and which exceed their TLV specified in the 2nd Schedule of the Factories Act (See Table 15 in Chapter-32).

Hazardous Process as defined u/s 2(cb) of the Factories Act, means any process or activity in relation to an industry specified in the First Schedule, where, unless special care is taken, raw materials used therein or the intermediate or finished products, bye-products, wastes or effluents thereof would -

1. Cause material impairment to the health of the persons engaged in or connected therewith, or
2. Result in the pollution of the general environment.

Dangerous Chemical Reactions as defined in clause (k) of Schedule 19 on Chemical Works u/r 102 of the Gujarat Factories Rules, mean high speed reactions, run-away reactions, delayed reactions etc. and are characterised by evolution of large quantities of heat, intense release of toxic or flammable gases or vapours, sudden pressure build-up etc.

Unit processes and operations mentioned in Sch. 4 u/r 68J of the Gujarat Factories Rules, when involve or likely to involve 'hazardous chemical' as defined in Part 3.38 above, activity in that installation or isolated storage is called **hazardous industrial activity**.

3.40 HAZOP:

Hazop (Hazard & operability) study is carried out by application of guidewords to identify all possible deviations from design intent having undesirable effects on safety or operability, with the aim of identifying potential hazards.

Hazop study is normally undertaken at an advanced stage of project implementation when the design criteria are well established. The study can be used for both new and working plants. They have to be carried out by multidisciplinary teams of experienced technical personnel having detailed knowledge of both the design ,and operation of a plant.

A preliminary Hazop study is intended to review the general parameters of materials processed, unit operations and layout of individual units and plant sub-units. A detailed Hazop study is required after the finalization of the designs to identify the potentially hazardous situations and to arrive at agreeable options to rectify design deviations and anomalies.

See Part 4.6 of Chapter -19 for details.

3.41 Health and Toxicology:

In its broad meaning, it includes toxicology of pesticides, heavy metals, industrial and agricultural chemicals and other environmental contaminants, effects of toxic materials, fertilizers, pesticides etc. on human, animals, plants and soil, contaminants, measurement and methodology, occupational and public health, use .and transportation of hazardous materials, industrial accidents and safety.

3.42 HSMD:

The Hazardous Substances Management Division (HSMD) is the nodal point within the Ministry for Management of Chemical Emergencies and Hazardous substances. The main objective of the Division is to promote safe management and use of hazardous substances including hazardous chemicals and hazardous wastes, in order to avoid damage, to health and environment. The Division is also the nodal point for the following three International Conventions.

1. The Basel Convention on the Control of Transboundary Movement of Hazardous Waste and their Disposal.
2. The Rotterdam Convention on the Prior Informed Consent (PIC) procedure for certain hazardous chemicals and pesticides in International Trade.
3. The Stockholm Convention on Persistent Organic Pollutants (POPs).

The activities of the division are carried out under three main thrust areas, viz.. Chemical Safety, Hazardous Waste Management and Solid Waste Management.

3.43 Incident:

An incident is any observable human activity sufficiently complete in itself to permit references and predictions to be made about the persons performing the act viz. cleaning an unguarded machine, failing to wear PPE, using compressed air on body, raising pressure or temperature unnecessarily.

It may result in accident or a near miss.

Incident for accident is defined as, 'an unplanned event or series of events that has or could have, caused injury to people and / or damage to assets and / or damage to the environment and / or loss of reputation.

3.44 Industrial Health & Hygiene:

This is connected with the protection of the manpower asset from industrial illnesses, diseases and other long-term accidental effects caused by industrial environment on human bodies. Indirectly it protects money asset.

Specific areas for consideration include: noise, dusts, gases, vapours, corrosives, toxic materials, ventilation, heating, lighting, humidity, environmental monitoring, biological monitoring, health checks, general and personal hygiene, counselling, health education, employee screening and placement and medical antidotes.

Occupational Hygiene Practice includes:

(a) Anticipation or Identification and Recognition of the possible health hazards in the work environment.

(b)' Evaluation of hazards, i.e. the process of assessing exposure (comparing with standard) and reaching conclusion as to the level of risk to human health.

(c) Prevention and control of hazards, which is the process of developing and implementing strategies to eliminate/ reduce to acceptable levels, the occurrence of harmful agents and factors in the workplace. It will also account for environmental protection.

See Chapter -24 for details.

3.45 Industrial Hygiene Audit:

Its aim is to examine industrial hygiene practices with a view to establish their effectiveness in preventing occupational illness and their conformance with standards and regulations. Audit report should indicate whether key industrial hygiene programme elements (not necessarily degree of compliance) are present or absent. The presence of a particular element merely indicates that the organisation is capable of moving towards desirable preventing goals. Audit worksheets should include data gathering format and major agents (heat, light, noise, radiation, contaminants etc.) review sheets. Industrial hygiene policy, laboratory facility, trained manpower; communication, structure etc. should also be reviewed.

3.46 Injury:

Injury (occupational) means an injury that result in death, loss of consciousness and administration of medical treatment, temporary assignment to other duties and transfer to another job, or inability to perform all duties on any day after the injury.

Injury is considered to include occupational disease and work-connected disability. **Work injury** is defined as an injury suffered by a person, which arises out of and in the course of his employment. It is an external damage to human body; disturbance or dysfunction resulted from an accident. By cause it may be mechanical, thermal, chemical, radiated or combined.

Injury is physical harm or damage to the body resulting from an exchange of (usually acute, mechanical, chemical, thermal or other environmental) energy that exceeds the body's tolerance.

Disabling injury is an injury causing death, permanent disability, or any degree of temporary total disability beyond the day of the injury (Accident Facts, 1997, NSC, USA).

Source of injury is the principal object such as tool, machine, chemical vessel or equipment involved in the accident and is usually the object inflicting injury or property damage. Also called agency or agent.

Property damage accident is an accident, which results in property damage, but in which no person is injured.

Non-fatal injury accident is an accident in which at least one person is injured, and no injury results in death.

See Chapter -4 for further discussion.

3.47 In-place (plant) Protection:

It means to direct people to quickly go inside a building and remain inside until the danger passes. It is preferred when evacuation is not possible or more risky. It is not safe if the vapours are explosive. People inside should keep doors, windows and ventilating system closed to stop ingress of toxic gases.

3.48 Isolation:

It means to isolate hazard area and to deny entry to keep people away from the area if they have not to play any emergency response role. It is the first step for any protective action that follows.

Isolation valve means a stop valve.

3.49 ISRS:

It means International Safety Rating System. Safety rating certificate is awarded by DNV to the hazardous plants. The system includes 20 safety elements, which are audited and based on the audit, safety rating number is awarded. The system provides scope for further improvement in safety areas to get higher rating number in the next audit.

3.50 Labour Protection:

It is defined as a system of legal acts and relevant socio-economic, technological and organisational measures ensuring safety and health, accident prevention, industrial hygiene and fitness to work.

3.51 Liability:

It means an obligation to rectify or recompense any in)ury or damage for which the liable person has been held responsible.

3.52 Loss Control:

In safety philosophy the word 'loss' has many meanings.

Loss includes injury, illness, disease or death to a person.

Loss includes damage to property, equipment, material, cost of replacement or damage to environment.

Loss also occurs in terms of time, money, material, production, sales etc.

Loss of time occurs in filling of accident forms and their reporting, record keeping, investigation of causes, searching for controls, travelling for medical and legal help, hospitalisation, Govt. offices, rehabilitation and restoration of public image.

Accident may cause any type of loss. Such losses are considered in counting the costs of accident.

Loss control is defined as a management system designed to reduce or eliminate all aspects of accidental losses that lead to wastage of company assets. In this context the company assets involved are manpower, materials, machinery, methods, manufactured goods and money. Thus a system of loss control is designed to improve the overall profitability of a company by reducing both the economic and social costs associated with loss producing activities. Legal, humanitarian (social) and economic aspects are included herein. .

Total Loss Control involves reporting to control centres all property damage accidents and injury causing accidents, supplemented by spot checks and safety audits.

3.53 Loss Prevention:

It may be defined as the application of engineering techniques in order to prevent or reduce the probability of occurrence of accidents that result in personal injury, damage to property, production, equipment, building etc. and those accidents having no end result i.e. the near miss accident. Prevention is an earlier part of control. Therefore it is better than subsequent cure. When fire, security, health, hygiene, pollution control, product liability and business interruption control are added to loss preventio n', it is called loss control'.

3.54 Major Accident:

As defined by Rule 2(j) of the Manufacture, Storage and Import of Hazardous Chemicals Rules, 1989, it means an incident involving loss of life inside or outside the installation or ten or more injuries inside and/or one or more injuries outside or release of toxic chemicals or explosion or fire or spillage of hazardous chemicals resulting in on-site or off-site emergencies or damage to equipment leading to stoppage of process or adverse effects to the environment.

Major Chemical Accident is defined u/r 2(f) of the Chemical Accidents (Emergency Planning, Preparedness and Response) Rules, 1996 by the words stated in above para but also including transportation.

3.55 Major Accident Hazard (MAH) Installation:

As defined u/r 2(g) of the Chemical Accidents (EPPR) Rules, 1996, it means isolated storage and industrial activity [u/r 2(c)] at a site handling (including transport through carrier or pipeline) of hazardous chemicals [defined u/r 2(b)] *equal to or in excess of the threshold quantities* specified in Schedules 2 and 3.

It is also similarly defined u/r 2 (ja) of the Manufacture, Storage and Impact of Hazardous Chemicals Rules, 1989.

Different rules (Safety Provisions) are applicable to such factories, installations or sites depending on "Threshold quantity" of hazardous chemicals listed in Schedule 1, 2, and 3, or processes mentioned in Schedule 4.

See Part 6 of Chapter - 19 for details.

3.56 Major Emergency:

Major emergency occurring at a work is one that may affect several departments within it and/or may cause serious injuries, loss of life, extensive damage to property or serious disruption outside the works. It will require the use of outside resources (off-site emergency plan) to handle it effectively.

Usually it is the result of a malfunction of the normal operating procedures. It may also be precipitated by the intervention of an outside agency, such as a severe electrical storm, flooding, crushed aircraft or deliberate acts of arson or sabotage.

Emergency due to operating conditions (uncontrolled reaction, small fire, small gas leak, spill, failure 'of power, water, air, steam, cooling media, scrubbing media etc.) and which plant personnel alone can handle locally (without outside help) is not considered as major emergency. Operating instructions in the Safety Manual should cover this area, though the on-site emergency plan will also be helpful.

3.57 Mistake:

Mistake, in the sense of safety, can be defined as an act of wrong opinion, judgement about a thing or situation which results in hazard or harm to a person, property or environment. It means to have wrong, perception about danger or to understand it wrongly so that it may cause hazard.

Like error, as explained earlier, it is an act of omission or commission resulting in hazard or hazardous situation.

Mistakes may be committed by men or machines and can be classified as personal mistake, mechanical mistake, technical mistake, historical mistake etc. It may be small or big. A gross mistake is called blunder.

Examples of mistake are wrong judgement of the speed of a vehicle, falling body or a moving machine, to perceive blue as black, to press 'start' button instead of 'stop' button, to press clutch or accelerator instead of brake etc.

Difference between 'error' and 'mistake' is thin and may be understood interchangeably.

3.58 NHWIS:

National Hazardous Waste Information System (NHWIS) is online Web based hazardous waste information system which gives the status of hazardous waste management in India. The database will be regularly updated by all State Pollution Control Boards on web and this will ensure updated status at all times. The NHWIS project has been developed by Environment and Forest Informatics Division of NIC in 'close consultation with Hazardous Substance Management Division (HSMD) of the Ministry of Environment and Forests. It gives

1. Records of Management of Hazardous Waste by Generating Units.
2. Status of compliance to the environment regulation.
3. Data on available disposal option.
4. Queries / Reports on hazardous waste management for authority and general public.

3.59 Nature and Natural Resources Conservation:

In its broad meaning, it includes all aspects of conservation of the flora, fauna, genetic resources, water, soil and eco-system.

3.60 Near miss:

It means any unplanned, sudden event that could have caused injury to man, materials (plant) or environment or could have involved a loss of containment possibly giving rise to adverse effect but not resulted in such accident.

If near miss is detected and prevented, possible accident due to that near miss can be avoided or prevented. If causes of near miss are not removed, they can result in accident. Therefore importance to identify and control near miss is more than that of controlling accident.

3.61 Negligence:

It means failure to exercise a reasonable amount of care or to carry out a legal duty so that injury or property damage occurs.

3.62 Noise Pollution:

In its broad meaning, it includes noise levels and their effects from domestic, construction, urban, industrial, transportation and other sources, acoustic measuring and instruments, noise surveys and standards.

3.63 Occupational Disease:

Occupational disease is impairment to health, illness, poisoning or disease caused to a person by exposure to any substance or process of the occupation. It may arise out of or in course of his employment.

Occupational Disease is also defined as a disease caused by environmental factors, the exposure to which is peculiar to a particular process, trade or occupation, and to which an employee is not ordinarily subjected or exposed outside of or away from such employment.

Occupational diseases are many and listed by the Factories Act, W.C. Act and ESI Act.

See Part 4 of Chapter-24 and Part 5 & 7 of Chapter-29 for details.

3.64 Occupational Environment:

It is the sum of external conditions and influences which prevail in the place of work and which have a bearing on tile health of the working population. It includes three types of interaction - Man and physical, chemical and biological agents; Man and machine or equipment, and Man and man.

3.65 Occupational Health:

It includes all aspects of a worker's health and his/her relationship with the environment.

Basic objectives of a good occupational health programme are:

1. To protect workers against health hazards in their work environment.

2. To facilitate their placement and ensure their suitability according to their physical and mental capacities and emotional make-up in work that they can perform with acceptable norms and without endangering self or the fellow workers.

3. To assure adequate medical care (including madical examinations and health records) and rehabilitation of the occupationally injured.

4. To encourage personal health maintenance.

See Part 4 of Chapter - 24 for details.

3.66 Occupational hygiene:

Occupational hygiene is a modern specialisation concerned with assessing and controlling hazards from atmospheric contamination, skin or body absorption, radiation, noise etc.

Occupational or Industrial Hygienist - Serves as the analytical preventive engineering arm of occupational medicine by applying specialised knowledge to the recognition, evaluation and control of health hazards in the work environment.

See Part I of Chapter-24 for details.

3.67 Occupational Poisoning:

Occupational poisoning is a partial case of occupational disease. Continuous or long time exposure to relatively small amounts of noxious or poisonous substances is conductive to a **chronic poisoning,** e.g. lead or mercury poisoning, lung diseases etc. Occupational poisoning is called the acute **poisoning or intoxication** if caused by penetration into the body of a noxious substance, or immediate local effects e.g. acid burn, fire or hot burn, sun burn, cold burn, gas inhalation etc.

3.68 Off-site emergency plan:

It deals with measures to prevent and control emergencies affecting **public** and the environment outside the factory premises. The manufacturer should provide the necessary information on the nature, extent and likely effects of such incidents to the Government authorities that make and operate this plan.

Schedule-12 of the MSIHC Rules, 1996 specifies 13 items. See Part 7.4 of Chapter-19 for details.

3.69 On-site emergency plan:

It deals with measures to prevent and control emergencies affecting workers and others **within the factory** and not affecting outside public or environment. It is controlled mostly by the plant personnel, resources and equipment. Factory management makes and operates this plan.

Schedule-11 of the MSIHC Rules, 1996 specifies 13 items. See Part 7.3 of Chapter-19 for details.

3.70 Oversight:

Oversight means overlooking of something, error or supervision. When there are more switches side by side and looking identical, an operator may operate a wrong switch by oversight. While counting many things, by oversight, someone may make mistake. Thus oversight denotes a state of mind by which error or mistake is possible due to lack of concentration or attention. Result of oversight is mistake or error. Oversight leads to unsafe action and that may result in accident.

The words - error, mistake and oversight - have thin difference, all leading to the causation of hazard or accident and concern with the state of mind or human behaviour.

3.71 Pollution:

In all its aspects it is concerned not only with the environment within the factory but also the immediate environment outside the factory. Control of air, land and water pollution protects the manpower asset directly and the money asset indirectly. Special attention should also be paid to noise and vibration as pollutant.

See Part 10.5 of Chapter-28 for statutory definitions of pollution, pollutant, environment etc.

3.72 Practicable:

In legal terminology, following three terms are used:

"So far as is practicable"- This means if something is practicable it should be done. It is not practicable to take precautions against any hazard which is unknown. But once the hazard is known, it becomes practicable to take necessary precautions against it.

"So far as is reasonably practicable"- This can be a defence by an accused person that precautionary action was not reasonably practicable by him. However he has to prove this. Ultimately the Court will decide depending on facts, evidences and balance between the cost and risk in assessing it.

"Best practicable means" - This indicates a duty to comply with by taking the best measures available in the light of current knowledge and according to means and resources. This duty lies between **so far as is practicable and so far as is reasonably practicable.**

The standard of practicability depends on current knowledge and invention.

The burden of proof that something was not practicable or not reasonably practicable lies on the accused. Inconvenience and expense cannot be used as a defence.

3.73 Probability:

It means the likelihood, chance or frequency that a considered (predetermined) occurrence may take place.

Probability includes possible frequency of hazard occurrence or possible frequency of effects due to any particular hazard.

Probability and severity (effect or consequence) are two ingredients of a risk. $R = P \times S$

3.74 Product Liability:

It extends the protection to all consumers of the company's products and is primarily concerned with the protection of money asset. Attention should also be paid to a product safety strategy.

3.75 Risks:

Risk is the combination of a probability of occurrence and its severity of consequence. Thus $R = P \times S$.

Risk is the likelihood of a specific undesired event occurring within a specified period or under specified circumstances. It may be either a frequency i.e. number of events per unit time or a probability depending on circumstances.

As per example risk of death for a man aged 30 is 1×10^{-3} per annum (i.e. during a year, out of 1000 such men, one may die) and that for a man aged 60 is 1×10^{-2} per annum (i.e. during a year, out of 100 such men, one may die).

Risk is an expression of possible loss over a specific period or number of operational cycles. It may be indicated by the probability of an accident times, the damage in rupees, lives or operating units.

Risk is expressed for uncertain eventualities and it may be classed as speculative or pure. Pure risk can only result in a loss to company, whereas speculative risk may result in either gain or loss. Risk, uncertainty, probability and chance are the words, which frequently recur and most familiar to insurance people. Risk and uncertainty are ingredients of life and we are constantly talking risks merely to stay alive. '

Individual Risk is the frequency at which an individual may be expected to sustain a given level of harm from the realisation of specific hazards.

Societal Risk is the relationship between frequency of hazardous event and the number of people suffering a specific level of harm (level of concern like LOG, IDLH, LD_{50}, LC_{50}, etc.) in a given population from the realisation of that event (specific hazard). It is a measure of the chances of a number of people being affected by a single event or set of events and is often expressed by f/n curves (frequency vs. no. of people affected).

See Part 4.1 of Chpater 19.

3.76 Risk Analysis:

It means to find out probability of a hazard occurring and then an estimation of its consequence or effect and its severity. It is quantitative.

For example, estimation of probability or frequency of possible explosion and its effect on persons and property in terms of deaths, injuries, house breakages etc. is called risk analysis.

See Part 4.3 of Chapter-19.

3.77 Risk Assessment:

It is the quantitative evaluation of the likelihood of undesired events and their consequences being caused together and a value judgement concerning the significance of the results after comparing with set, legal or accepted values or standards.

It is a judgement of significance or acceptability of risk identified by risk analysis and comparing against social, political or legal criteria, e.g. comparison of measured or calculated risk with the permissible safe limits and judgement regarding safety (whether the risk level is within or exceeding the safety limit) gives risk assessment.

Though Hazard identification is a part of Risk Assessment, term HIRA ie Hazard Identification and Risk Assessment is also used by some companies.

Objective of risk assessment are :

1. Identification of vulnerable zones (losses of persons and property) of the premises.
2. Estimation of hazard distances for the maximum credible accident (MCA) scenarios.
3. Suggestions for risk mitigation measures an delineation of approach to disaster management plan (DMP).

See Part 4.3 of Chapter-19.

3.78 Risk Counter:

Risk counter is an iso-risk line on the map which a hypothetical individual staying there unprotected and for 24 hours per day would be subjected to a defined probability of fatal harm due to exposure to hazards induced by the industrial activity. This risk indicator is most frequently used to quantify the off-site risk to the public and is expressed on a per year basis.

Risk Counters are calculated by determining the consequences from a number of scenarios. By adapting certain criteria for death from toxic substances, radiation heat load from fire and explosion over pressure, effect and damage distances can be determined.

Risk transects are like risk counters, but are used for the risk from transportation by road, rail, pipeline etc.

Risk counters or 'foot prints' are plotted on the map of the premises and its vicinity (area) to see the effect of damage distances reaching to the public or surrounding environment. On each periphery of a counter, risk level should be mentioned. Counters may indicate risk zones like low, medium, high, highest etc.

3.79 Risk Management:

It may be defined as the organisational set-up for prevention or minimisation of the adverse elects of risks within a company, via the identification, evaluation and control of such risks by finding and applying remedial measures.

It is decision-making and establishing ownership of actions and monitoring to contain within limits of criteria.

Risk Management includes following Steps

1. Hazard Identification
2. Hazard Analysis
3. Hazard Assessment
4. Risk Analysis and
5. Risk Assessment.

It includes management for safety (injury prevention), damage control, loss prevention and loss control. .

See Part 4.3 of Chapter-19 for details.

3.80 Safety:

In general terms, safety means freedom or protection from harm, danger, hazard, risk, accident, injury or damage. In an .industrial context, it means the minimization of contact between human and hazard and is predominantly concerned with the prevention of physical harm (injury) to persons or/ and property. Its concept is explained in detail in Chapter-1.

Industrial safety is that condition of enterprise operations in which, by controlling hazards and risks, accident free production is achieved.

Safety is defined as a positive, organized activity or program based on knowledge of the reaction between man and his working environment, which aids business enterprise by minimizing death, losses caused by injuries, health impairment, fires, explosion and other occupational accidents.

Safety is opposite (antonym) of danger. Freedom from hazards represents absolute safety, but this is an ideal, which is seldom realised. Safety is rather a matter of protection from hazards.

Safety is a situation with acceptable risks. Thus safety mean's to bring or keep the hazard level, below permissible safe level. It includes safety, health and environment (SHE or HSE) protection including protection of property.

Operational safety concept is a strategy for process control, incorporating a hierarchy of monitoring and controlling process parameters and of protective action to be taken.

3.81 Safety Audit:

It is a critical examination of all or part, of a total operating system with relevance to safety and to suggest improvements and up gradation.

A safety audit is intended to measure the effectiveness of a company's safety programs in every respect. The objectives should be clearly defined such as-'

1. To carry out a systematic and critical appraisal of all potential hazards involving personnel, plant, services and methods of operation.

2. To ensure that the occupational health and safety standards fully satisfy the legal requirements and those of the company's written safety policies, objectives and programs.

The word 'safety audit' is also used for 'safety inspection' intended for

1. Identification of possible loss situations.
2. Measurement of the potential losses associated with these risks.
3. Selection of methods to minimize the losses.
4. Implementation of the selected methods within the company and
5. Monitoring of the result and suggesting further improvement based on review.

See Part 6.8 of Chapter-19 for details. See IS: 14489 also.

3.82 Safety Manager:

Generally connotes a person responsible for a safety organization and its activities. This person is concerned with the conduct of the safety programs at the plant(s) for which he is responsible. He may have under his immediate supervision, one or more safety engineers or officers, an industrial hygienist, industrial psychologist, risk manager and other employees knowledgeable in safety.

Risk Manager is responsible for the function of a safety manager and also for the insurance programs and other activities to minimize risks and accidental losses.

See Chapter -6 for details.

3.83 Safety Management System:

Safety Management System is defined as collectively those elements in the operator's management system which ,ensure that all loss exposures inherent in the operation have been systematically identified and risk assessed and that arrangements are in place to control the risks in these loss exposures to a level as low as reasonably practicable (ALARP) and to minimize the consequences of any failure of tile control system should, the need arise, and that the information, training, auditing and improvement processes are in place.

3.84 Safety Premises:

It is the duty of an owner or user of land to keep his premises in a condition that is reasonably safe for those lawfully there, e.g. duty of an owner of cinema or auditorium.

3.85 Safety Report:

It is the written presentation of the technical, management and operational information covering the hazards of a major accident hazard (MAH) installation and their control in support of a justification for the safety of the installation.

Schedule -8 u/r 68-J of the Gujarat Factories Rules or u/r 10(1) of the Manufacture, Storage and Import of Hazardous Chemicals Rules, 1989 prescribes such report with 10 items.

See Part 6.8 of Chapter-19 for details.

3.86 Safety Committee:

It is prescribed u/s 41-G of the Factories Act, 1948 and u/r 68 F & Y of the Gujarat Factories Rules. It is similar to the safety team.

See Part 11.3.1 of Chapter-6 for details.

3.87 Safety Team:

It is a group, which may be established by the works management for specific safety purposes, - e.g. inspections or emergency planning. The team should include workers or their representatives where appropriate, and other persons with expertise relevant to the tasks.

3.88 Security:

It protects the material, methods, manufactured goods and money assets by security personnel and Insurance. Generally it includes security staff (guards) in 3 shifts ie 24 hours for the protection of company assets.

Security should be distinguished from safety which is mostly concerned with protection from hazards by engineering and other control methods and as explained in part 3.80.

3.89 Site:

As defined u/r 2(m) of the MSIHC Rules, u/r 2(k) of the Chemical Accidents (EPPR) Rules and u/r 68J(1)(g) of the GFR, it means any location where hazardous chemicals are manufactured or processed, stored, handled, used, disposed of and includes the whole of an area under the control of an occupier and includes pier, jetty or similar structure whether floating or not.

Schedule-7 for notification of site should be referred under MSIHC Rules.

3.90 System Safety:

It is the concept 'to have an accident, there must be a hazardous or unsafe condition'. If that unsafe condition can be eliminated or suitably controlled, there will be no accident even if there is an error on the part of any personnel involved. Example is an interlocked guard, which prevents accident due to human error. To minimize accidents, it is necessary to eliminate or control any of the hazards involved at each stage of design, manufacture, test, operation and maintenance.

System safety requires auto controls to make the system so safe that human error may not result into accident.

3.91 Transport of Hazardous Chemicals:

It means movement of hazardous chemicals by any means over land, water or air.

See Part 14.2 of Chapter-18 and Part 6.2 of Chapter 28 for details.

3.92 Ultra-hazardous Operations:

Any person who conducts an operation that involves abnormal risk to others is strictly liable for injury or damage that results, even if these operations were conducted with care.

3.93 Uncertainty:

It exists only in our minds and has much the same meaning as doubt. Its opposite is often regarded as faith or firm determination.

3.94 Unsafe Act: -

It means either a positive act i.e. commission of an act or a negative act i.e. omission or failure to perform an act which a prudent man should not have done and which results in hazard, accident or injury. The unsafe act might be deliberate (mischief, sabotage etc.) or committed due to absence knowledge, ignorance or through forgetfulness (human error, mistake etc.). The unsafe act may be the sole accident cause or one of several causes. Examples are standing under suspended load, design mistake, starting machine without authority or warning, removal of safeguard, chance taking, wrong interpretation of safety rule, not following the safety precaution, poor vision or judgement etc.

Unsafe act is concerned with the human being and can be corrected by the action of the human being only. Training plays an important role. Even if the condition is fully safe, an accident may happen because of the unsafe act. At the root of creation of unsafe condition, many times the underlying cause is unsafe act i.e. human failure somewhere, which can be detected and corrected. According to H.W. Heinrich, @ 88% accidents are due to unsafe acts. He considered unsafe acts responsible for most of the unsafe conditions.

See Part 8.2.2 of Chapter-4 for details.

3.95 Unsafe Condition:

It means existence of a mechanical, physical, chemical or environmental condition, situation or state of affairs, which may cause hazard or accident. The unsafe condition might be the result of any unsafe act (human failure) or accidental failure or alteration of the safe condition. The unsafe condition may be the sole accident cause or one of several causes. Examples are, wrong design, no guard on dangerous part, no control of chemical process, no provisions of safety devices, poor light, poor ventilation, confined space, high noise etc.

Unsafe condition is concerned with the position, situation, existence or accidental alteration of the safe condition into such position, situation, existence or state of affairs leading to the causation of any hazard or accident. Such condition may be because of any unsafe act or not. Acts of God are unsafe condition. Unsafe condition can be rectified, repaired or made safe mostly by engineering controls.

3.96 Unsafe Production Factor:

It means an industrial agency or agency part, which under certain conditions may invite an injury or disease.

3.97 Vulnerability Models:

Vulnerability models are used to determine how people may be injured by exposure to heat load due to fire, blast wave due to explosion or toxic load of the released material. Such models are designed on the basis of animal experiments or on the basis of the analysis of injuries resulting form accidents, which have already occurred. Such models make use of a probit equation to forecast fatalities.

3.98 Wastes:

In its broad meaning, it includes collection, treatment, disposal, reuse and recycling of agricultural, animal, industrial, municipal and domestic wastes; procedures, engineering, plant operation and quality control methods applied in such processes and other aspects of waste management.

3.99 Water Pollution:

In its broad meaning, it includes all aspects of fresh water pollution (including ground water), pollution of water bodies, chemical and biological contaminants, marine pollution, detection, chemical analysis and monitoring of water pollutant.

3.100 Worst Case and Maximum Credible Scenarios,

The worst-case scenario (rarely possible) is defined as the release of the largest quantity of a regulated substance from a single vessel or process line failure that results in the greatest distance to an end point, eg catastrophic failure. It considers the failure of all control systems and release of the whole mass resulting in maximum damage.

Maximum Credible Accident (MCA) Scenario indicates most believable, reasonable, trust worthy, convincing, likely or possible accident scenario and damage distance based on it. MCA scenario takes into account the effect of existing control measures also. It considers the malfunctioning of the control system, opening of safety valve, flange joint, pipe line etc. and failing of some safety devise.

Alternative release scenarios are scenarios that are more (lively to occur than the worst-case scenario and that will reach an endpoint off-site, unless no such scenario exists.

The distance to the end point is the distance a toxic vapour cloud, heat from a fire, or blast waves from an explosion will travel before dissipating to the point that serious injuries from short-term exposures will no longer occur.

Computer models are more useful to determine such credible scenarios and to get the damage distances. Some latest computer models are CIRRUS, ARCHIE, PHAST, SAFETI and ALOHA etc. CIRRUS includes four important models in one package. These models are Source Term Model, Dispersion Model, Fire Model and Explosion Model.

4 MESSAGE OF THE WORD 'SAFETY'

The word 'safety' is defined in foregoing section. Now its message is philosophically explained below by each letter of its spelling.

S - Science for Safety of Self and Society.
A - Art and Action for Accident Avoidance.

F - Foolproof safety with Fail-safe devices including system safety. Factories Act is the safety backbone for industry.

E - Engineering controls are most important and must first be provided 'and maintained for safety.

T - Teaching and Training for safety to all concerned including workers and public.

Y - Young Person & Young Mind to work for safety. Yawl to save the humanity.

Five 'E's are stated as fundamentals for safety. They are Education, Engineering, Enforcement, Enthusiasm and Example setting. See part 8.4 of chapter-4 also.

Five 'L's are important-Learning, Leadership, Loyalty, Labour protection and Lawfulness.

Five'M' s are important - Man, Material, Machine, Money and Management.

Five T's are important - People, Protection, Productivity, Prosperity and Proficiency.

Philosophy of each of these words can be discussed with plenty of examples. They all need utmost attention.

5 PHILOSOPHY OF ACCIDENT CAUSATION

We are at the junction of old and new theories of safety philosophy which needs some clarification to avoid confusion and to make the safety approach more correct, more perfect and more powerful.

The concept of 'unsafe act as the main causative factor of more than 88% of accidents' has, now, become an old theory though it has not lost its full significance. This was more strongly propounded by H.W. Heinrich, the great philosopher of safety and accident prevention work. He estimated that 88% of 75000 accident cases reviewed were due to the unsafe acts of persons (Chapter-4). R.W. King and John Magid in their book of 1982 (see reference no. 10) also presumed human failing or unsafe act as an underlying cause of unsafe condition. This philosophy emphasizes the unsafe act as predominant factor, and continuous need to train our workers for their safe work practices.

The psychologists explained the theory of accident-proneness (Chapter-3) and held responsible these accident-prone people for majority of accidents. This has also led to the same old theory to find out the cause of accident in human behaviour (unsafe act) only.

This old theory is 'obviously picked up by majority of employers and they do not pay proper attention or invest sufficient money for safety because they follow this theory and say, 'Safely is mostly (88%) concerned with employee's behaviour and it is their duty to correct themselves, why should we invest much for only 12% of accident causes?' .This philosophy causes great harm to the progress of safety movement, and it needs to be discarded as early as possible.

But the research work was continued on the real causation of accidents and it is now inferred that the real cause of accident is an unsafe condition, which must be detected properly and removed in such a way that even human error or mistake may not cause any accident. Interlock or automatic guards, trips and alarms, checks and counter checks, level cut off, auto-stop, auto control and auto-correction etc. are ways and means to protect against unsafe conditions due to human error. This, theory is developed as a new engineering discipline and system safety. It is well explained by Willie Hammer and Blake (Chapter-4).

Willie Hammer states, "Observation over the years has shown that this premise (accident-proneness) is incorrect. There are persons who have more accidents than other persons in similar situations." Explaining the new concept of system safety he says "system safety conceived that accidents could be caused by personnel error, malfunctions and failures of equipment, dangerous characteristic of equipment or adverse environmental conditions. Personnel error could have been by designers, test and maintenance men, workers or anyone connected with the process or product. To minimize accidents, it is necessary to eliminate or control any of the hazards involved at each stage of design, manufacture, test, maintenance and operation. If Heinrich's data were re-examined in accordance with these newer ideas, it might be found that 88% of the accidents were probably due to causes other than error by the person immediately involved."

Blake has also criticized the ratio theory of Heinrich as fallacious as it rests on a false assumption that work connected injuries are the result of either unsafe conditions or unsafe acts. The real reason in most of the cases is a combination of correctable unsafe condition and faulty behaviour and frequently there are multiple factors of both. To classify accidents as either unsafe act or unsafe condition is over simplification and many times data is not available to find out any single cause and the causation has a sequence of events creating hazard or accident as a result of combination of unsafe condition and action. Thus accident classification requires high skill and observation and must be proper.

The real Philosophy of Accident Causation:

It can be concluded as under:

1. It is true that unsafe condition and unsafe action, both, exist and play their role in accident ' causation.

2. There mayor may not be any single cause as 'unsafe condition only' or 'unsafe action only'. Proper fact data must be searched to find out the real cause of accident. In want of sufficient or correct data, no conclusion should be drawn about the real or sole cause of accident.

3. 'Why did the man make mistake?' should be thoroughly examined in depth and working or environmental condition must be detected as a root or real cause of his human failure. The poor vision and poor illumination, both, are unsafe conditions, and can be rectified by necessary spectacles and increase of light.

4. If the causes are combined, classify them and try to remove them priority wise.

5. Unsafe condition has more accident potential and can lead to a serious accident. Therefore it must be detected first by various safety inspection methods or safety audits and must be removed by proper engineering controls. Unsafe conditions have caused major accidents in past.

6. Unsafe action requires behavioural or psychological study of workers, which should be carried out and unsafe action should be rectified before it may cause any unsafe condition, hazard or accident. The purpose of this causation analysis is to train the workers properly and to minimize man-made hazards or unsafe conditions timely.

7. All causes of accident should be considered together, instead of analysing and separating as unsafe action or unsafe condition and blaming one or the other. It is not cheaper to prolong hazard than to remove it.

8. New study of accident causes reveals that 3% were due wholly to mechanical cause, 2% due wholly to unsafe acts "and 95% to a combination of both the causes. The percentage may vary. to

some extent in different case studies, but it is the best approach to safety that mostly the causes are combined or complex and they all should-be removed wholly.

9. The concept of accident proneness is not the real cause of majority of accidents. This concept has historical value (as it was originally derived from psychological studies), but it requires proper understanding and its causes (including faulty working conditions) should be removed. This concept is explained at length in the next Chapter.
10. Employer's mentality based on old theory of "unsafe act as predominant accident factor" must be removed and they should follow the new concept that percentage of unsafe act or unsafe condition are not important, the causes are mostly combined, are equally important and require self motivated sincere efforts and full money investment in removing all of them and making the man, machine, material, manufacturing process and all environment fully safe and healthy. Good working conditions contribute less error and less hazards. Information and training to detect and remove hazards at any level are utmost necessary.

11. It should be accepted that majority of accidents happen with contract workers as they are illiterate, untrained, unskilled, less equipped and poorly supervised. Therefore more attention must be paid for their safety.

6. PHILOSOPHY OF TOTAL SAFETY CONCEPT:

Based on above discussion, phylosophy of **total safety concept** should be as under:

1. Safe and clean work place and working conditions.
2. Safe and Ergonomic design and application to reduce health hazards.
3. Safe work method, job performance and the job itself.
4. Detection and assessment of risk, deciding what precautions are needed and application of eco-friendly process technology and hazard control technology.
5. Prevention and control of situation and environment including exposure to hazards and well maintenance of all control measures.
6. Improved methods of selection, training, placement and supervision of workers.
7. Periodical medical health check up and follow-up of medical advice for workers.
8. Periodical psychological study of human behaviour for safety.
9. Public awareness and preparedness programs i.e. community involvement for public health & safety.
10. Periodical review of all safety programmes and necessary change and improvement where required.

This new philosophy of safety is the f oundation of safety structure and safety culture.

E X E R C I S E

1. Explain the Objectives of Philosophy of safety OR Explain the Nature and Subjects of safety philosophy.

2. Is the term 'accident' defined under the Factories Act? Give any two definitions of 'accident' and explain them with illustration.

3. Discuss the term with example:

1.	Accident.	2.	APELL.
3.	CASH	4.	Dangerous Occurrence.

5 Environment.
6. Error.
7. MAH installation
8. Injury.
9. HSMD
10. Mistake
11. Near miss
12. Occupational health
13. Oversight
14. Product liability
15. Safety Management System.
16. In-place protection.
17. Safety premises
18. NHWIS
19. Safety audit.
20. Major accident.
21. System safety
22. Risk Assessment
23. EMP
24. Ecology
25. Noise pollution
26. ISRS
27. Vulnerability Models

4. Distinguish with example:

1 Accident & Major accident.
2 Emergency & Disaster.
3 Hazard & Risk.
4 Error .& Mistake.
5 Analysis & Assessment.
6 Near miss & Accident.
7 Loss control & Loss prevention.
8 Occupational Health & Hygiene.
9 Onsite & Offsite emergency plan.
10 Safety & Security.
11 Safety Manager & Risk Manager.
12 Unsafe act & Unsafe condition.
13 Risk Counter & Damage distance
14 Consequence & Vulnerability Analysis
15 The Worst Case scenario and MCA scenario.

5. Explain the real philosophy of safety emerging from old and new theories.

6. Explain the philosophy of 'total safety concept'

CHAPTER – 3

Safety Psychology

THEME

1. NEED OF SAFETY PSYCHOLOGY

Safety is mostly concerned with control of accidents (control includes prevention). The accidents are due to unsafe conditions or unsafe actions or their combination. As per H.W. Heinrich's theory, majority (88%) of the accidents are due to unsafe actions of the workers. In modern plants, where the working conditions are good and well maintained, some accidents take place due to unsafe action i.e. human behaviour of the workers. Therefore it is an important task to study this unsafe action or human behaviour, to find out its causes, effects and remedial measures and to remove them. *It is important to study first the human machine and its behaviour before studying any machine made by him*. **Psychology** and **psychologist** do this task. This shows the need of psychological study in the field of safety also.

At present knowingly or unknowingly psychological principles are applied in accident control theories, but, well study of psychology or human mind brings perfection in them. All safety officers, engineers, supervisors and inspectors should have good knowledge of psychology to understand and rectify the human behaviour, which is one of the causes of hazard occurrence and accidents. Need of applied psychology for safety in industry should be properly recognised.

Psychological safety measures put stress on information, instruction, training and supervision for safe performance, which is also a statutory need (Sec. 7A) under our Factories Act, 1948.

Human Resource (Psychology) Department of industry should organise safety-training programmes for all types of workers.

2. PSYCHOLOGY AND ITS BRANCHES

Psychology is a study of human behaviour and includes all behavioural aspects viz. mind, body intelligence, attitude, aptitude, morale, performance, proficiency, skill, learning, training, motivation, aspiration, inspiration, satisfaction, liking-disliking, action-inaction, fatigue, boredom, absent mindedness, accident-proneness, effect of working environment, labour policy, management, age and sex, individual differences, conflicts, personality and interest, human error and accidents, worry, unrest, synchronisation of mental and muscular faculties, mental and physical reactions, sense of duty or responsibility, motive or lack of motive, humanitarian impulses, disposition etc.

Psychology is defined as study of human (also animal) behaviour with the aid of scientific methodology. It is an art and science of mind. It collects facts of human behaviour by using scientific methods ' viz. experiment, observation, time-motion study, field study, case study etc.

Psychology is a branch of philosophy and is established as an independent branch. Like other sciences, it also aims to reduce all phenomena (mostly human) to cause and effect. It accepts causation in behaviour as a fact. It demands analysis of events, situation and past experiences to correct the behaviour

It has two aspects, scientific and applied. In its scientific aspect it considers research and discovery of information related to human behaviour. When such information is applied to practical problems of human life, it is said an applied or professional aspect of psychology.

Branches of psychology are given in Table 3.1.

Table 3.1 : Branches of Psychology

	Branch Known As	Area of Study
1	Engineering psychology or Human factor psychology or Human Engineering	Human behaviour as a function of self or personal factors like physical traits, mental traits, ability of work, attitude, aptitude, morale, frustration etc. Human behaviour as a function of work situation or environmental factors like temperature, ventilation, light, noise, vibration, ergonomics, job situation, fencing, guarding, house-keeping, training etc.
2	Clinical or counseling psychology	Abnormal aspects of behaviour
3.	Educational Psychology	Process of learning and education
4.	Development psychology	Development in behaviour with growing age
5.	Social psychology	Influences of society (other people or groups) on an individual's behaviour.
6.	Experimental psychology	Experimental method to study behaviors and to discover principles that govern behaviour
7.	Personality Psychology	Human personality
8.	Industrial psychology Or Applied psychology	Application of principles of psychology in trade, business and industry.

3. INDUSTRIAL PSYCHOLOGY

Industrial psychology is concerned with the study of human behaviour in those aspects of life that are related to the production, distribution and use of the goods and services of our civilization.

Application of the psychology to trade, business or industrial field is called industrial psychology, and generally covers the following areas given in Table 3.2.

Table 3.2 : Sub - branches and Areas of Industrial Psychology

	Sub-Branch	Area of Application
1	Personal psychology	Selection, training and supervision of people in industrial / business setting. It also studies communication.
2	Managerial psychology	Problems of management in industry.
3	Engineering psychology Or Human Engineering Or Human factor Engineering or Ergonomics	Effect of working condition, situation or environment and includes factors like over crowding, light, ventilation, temperature, sitting arrangement, design of machine, tools, controls, gauges, switches, equipment, work method, job situation so as to be safe and convenient to the workers.
4	Consumer psychology	Relationship between manufacturer and consumers of their products or services.
5	Organizational psychology	Total (overall) functioning of an organization, factory, office, management etc. including topics like motivation, leadership, communication patterns, work group by dynamics, organizational structure, process etc.

Subjects of Industrial Psychology:

Ordway Teed says, "Every major management problem is in part psychological."

Herbert Moore -describes in his book six industrial problems for psychologists to solve:

1. Employing the worker.
2. Educating and training the worker.
3. Caring for the health and safety of the worker.
4. Helping to provide for the economic security of the worker.
5. Establishing workable employer-employee relationship and
6. Cooperating with the advertising and sales forces.

For proper selection of a right man for the right job, various tests are suggested such as service commission's tests, intelligence tests, general ability tests, special ability tests (mechanical and electrical), personality tests, aptitude and attitude tests, achievement tests etc. Various incentives are also suggested to motivate workers.

Main Subjects of Industrial Psychology:

Appraising and training the worker, accident-proneness, causes and prevention of accidents, employee fatigue and boredom, the problem employee, motivation the psychological factors in labour turnover, consumer contracts and selling -are the main subjects of industrial psychology.

4. SAFETY PSYCHOLOGY

Safety psychology is a part of industrial psychology and can be explained as under:

4.1 Meaning and Aim:

Safety psychology is a study of human factors and behaviour contributing to the causation of hazard, accident or unsafe environment or situation and the application of remedial measures to prevent and control them by improving human behaviour for safe job performance and relations with others to maintain the safety.

Thus safety psychology studies a **person** why he commits accidents, under what circumstances and what are other contributing factors affecting his behaviour or making him accident prone and how such behaviour can be corrected to rectify his unsafe actions to achieve the goal of overall safety which includes the techniques of accident prevention.

Fig. 3.1 Safety of human being at the centre

Tile human being is at the centre of such study and therefore it is called the human engineering. See fig. 3.1. The concept of safety as human engineering is its psychological part. It aims at the rectification of human errors, human factors and unsafe actions as the causes of accidents or unsafe environment. H.W. Heinrich says in his old book on Industrial Accident Prevention that psychology lies at the root of sequence of accident causes. For details see next chapter.

4.2 Present Psychological Safety Problems:

Field of safety psychology is applicable to employer and employee both. Accidents are the results of faults of employer or employee. The main responsibility to provide and maintain safe working conditions, safe environment and protective equipment lies upon the employer, however, the practical field of effort for prevention through psychology and use of .protective equipment, is applied largely to the employees. The employees being more in number render more chances of human faults. Therefore it is their great, individual and group or collective responsibility to minimise their human faults to prevent accidents and to maintain safety.

Present psychological safety problems can be divided in two parts: Employer's problems and Employee's problems. Ultimately they create problems for society and nation also.

4.2.1 Employer's Problems:

Employers' expectation or fear from the employees not only in the form of production targets, but, in the form of attitudes, loyalties and cooperative efforts, is as important to the psychologist as the employers want to know about the resources, desires,. motivation and capacities of their employees.

Workers' disobedience, indiscipline, sabotage, mischief, non-using of safety equipment or appliances or damaging them, not following the safe close down of the plant for the purpose of safety, and not even allowing others to carry out such safety duty and practising strike or go slow to the extent of endangering safety of self, others and surrounding public are the present psychological problems creating worries for employers. They expect help from the Government which ought to be given, but, it must be noted that the only effective key to correct or improve human behaviour lies in die self discipline or self-efforts and outsiders can contribute little if the wrong doer is firmly determined not to improve himself. The Government may help in die field of law and order but it can hardly improve the human behaviour, which needs special efforts.

There are some statutory provisions in the Factories Act 1948 to punish workers for their offences regarding safety, but the Governments are reluctant to operate them against the workers. Even if they are operated, no worker will give evidence against a worker and other witness if come forward, they may be attacked by the mob-mentality. Thus in the atmosphere of deliberate indiscipline or mischief in the field of safety, really, it is a challenging problem for psychologists to solve in the interest of safety. Trade unions should also contribute to solve this problem.

The workers must understand that safety of them and others lie in their hands. Safety is a subject of co-operation and construction and not destruction. If safety is not maintained, nobody will be happy and they themselves may lose their limbs or lives. Compensation cannot bring the life back. Safety of anybody's life is of prime importance. No human behaviour is morally or legally permitted to endanger or take away anybody's life or to cause damage to plant, machinery, production or environment, as they all ultimately result in the national loss. Let us always maintain safety and solve our problems in safe atmosphere only. Let us perform this safety-duty first, enjoy the right and let others also should enjoy their rights. This is the only good motivating force to mould the human behaviour to maintain safety. Employers' regular efforts to give such type of HRD training to their employees can be useful.

Apart from employer's duty towards workers, new legislation during last ten years has imposed duty towards the public also. Under the Factories Act, Environment (Protection) Act, Public Liability insurance Act and Chemical Accidents (EPPR) Rules, die general public is to be informed about the hazards; controls and their role in emergency. Any citizen or member of a Crisis Group can demand such information from employers. This situation has created worries for the employers and they seem to be reluctant in providing such information to public. In case of a major accident affecting public, the Police and other authorities may prosecute them. A solution to this problem is the willing compliance of law only.

4.2.2 Employee's Problems:

Employees' expectation from the employer not only in the form of pay, but in the form of security, opportunity for advancement and protection, is as important to the psychologist as what they want for themselves in the form of self-expression, recognition and acceptable working conditions and environment.

It is the fact with many small and medium-scale factories that workers' expectation, as stated above, is rarely .fulfilled. The exploitation of poor, uneducated, unorganised and mostly contract workers are still continued and they have to work long working hours under bad and unsafe working conditions and environment. Most of the educated workers do not get satisfactory wages and are de-motivated. Trade unionism may change their attitudes. Even statutory requirements for health, safety and welfare are not provided for. They have no recognition, self-expression, protection, security or opportunity. They work only because of their livelihood, economic need or helplessness.

The need, and work of a Safety Officer are still not recognised wholeheartedly by the majority of the employers. This situation discourages and de-motivates the Safety Officers. Due importance must be given to all safety employees and their work.

In spite of factory and safety legislation and inspectorate, the working conditions for workers are found generally not good. With few exceptions in some good factories, most of the places need improvement for safe environment. The machines are not guarded, floor openings not covered, safe means of access not provided, safety devices neither provided nor working, occupational diseases go undetected and unreported, dusting, fuming, gassing and pollution constantly pollute the atmosphere, pressure vessels, lifting machines and other dangerous machines and processes are not fully safe and they cause many accidents. The same is the case with many chemical vessels, their fitting and maintenance. Workers also do not complain much, as they see such situations since long, as regular affairs, routine matters or have less hope for improvement.

Who is to blame for this? After all human beings are involved and they blame each other. Employers say they provided the safety arrangements but the workers do not maintain them. Some say they have no money to invest for costly safety equipment and the Government should give subsidy to them. Workers say opposite, that the safety devices are not provided or not working since long and nobody hears their complaints. Factory inspectors prosecute for many violations but mostly for other than safety. Only in case of accidents or special cases they prosecute for safety. Their finding is such that many employers do not .provide or maintain safety devices for many reasons, and strict and repeated follow-up is not possible due to shortage of staff, time and manifold work. People blame the inspectors also. This is the real picture -posing psychological problems at many fronts. The nature or extent of problems may vary with the place and person, but the general picture remains the same.

Blaming each other will not solve the problem. All are right or wrong to some extent. It is doubtlessly, the primary duty of all employers to provide and maintain the safety requirements. There should be no defence for this. Safety expenditure must be planned from the beginning and should be provided every year. Safety committees should be formed with the inclusion of workers representatives to review safety conditions. The unsafe conditions and actions must be removed by joint efforts. The workers, supervisors and all workpeople should strive for safety. Preventive-and corrective maintenance should be carried out regularly. Such should be the attitudes. The Factory Inspectorate should be strict for safety compliance and should give all guidance for safety knowledge. Trade unions should also contribute much including safety wareness and training. The human behaviour for safety must be motivated and improved.

5. ACCIDENT CAUSATIVE FACTORS

Main Division of Factors affecting Work:

Main factors affecting work performance or influencing actions of people are broadly divided as (1) Environmental factors and (2) Human factors.

The **environmental factors** are due to (1) Physical work and (2) Physical, chemical, biological and ergonomic environment. The physical environmental factors are heat load due to heat, humidity, thermal radiation, air changes, velocity, ventilation, illumination, noise, vibration, etc. The chemical factors are corrosive, toxic, flammable, or explosive substances, dust, fumes, gas etc. The biological factors are bacteria, virus and microorganisms. The ergonomic factors are layout and design of machinery, equipment, tools, controls, workplaces and housekeeping.

The **human factors** are due to two aspects (1) Physiological and (2) Psychological.

The **physiological factors** are physiological. fitness of an individual worker estimated from his Maximum oxygen uptake capacity. Sex, Body build, Age, Muscular work. Posture, Clothing, Nutrition, Training, skill, and Occupational workload.

The **Psychological factors** are Attitude, Aptitude, Frustration, Morale, Motivation, Individual differences etc.

Industrial accidents are either due to **unsafe conditions** (situation or environmental factors) which include mechanical causes (unguarded machinery, defective equipment, dangerous situation etc.), chemical causes (toxic exposure, dust, fume, fire, explosion and variety of ill-effects due to hazardous nature of chemicals, their storage, processes and equipment), and physical causes (physical workload, working hours, heat, light, noise, vibration and working conditions) physiological causes (Age, sex, body-build, posture, physical fitness, health, physical fatigue, nervous strain, sickness etc.) or due to unsafe actions which include psychological causes (motivation, skill, training, carelessness, recklessness, habit, worry, emotional upsets, irresponsibility, poor attitudes etc.).

Generally engineers, industrial hygienist and safety officer try to remove unsafe conditions and a physiologist and psychologist deal with unsafe actions. The details of physiological factors are discussed in Part 2 of Chapter-24.

The psychological factors being the main subject of this chapter are discussed below:

6. GENERAL PSYCHOLOGICAL FACTORS

The psychological factors (a part of human factors), affecting human behaviour or influencing actions of people for work performance are many. The human attitudes and aptitudes, frustration and conflict, morale, individual differences, acclimatization, skill and training, need and job satisfaction, motivation and aspiration, participation, incentives and job evaluation, fatigue, boredom and monotony, accident proneness, group dynamics, labour policy and turnover, personal selection and classification, problem worker etc. are the main psychological or personal factors affecting human behaviour. Some psychological tests are also carried out to measure some of these factors.

H.W. Heinrich's study of accident analysis emphasised that 88% of the accidents were due to unsafe act of the people,, and above factors were the main sub-causes or reasons for such unsafe acts, and therefore the study and application of remedial measures from this psychological point of view can prevent 88% of the accidents which is the great service of psychology to the industrial safety. No officer working for safety should ignore this fact. He should pay proper attention to correct the human behaviour of self and the workers due to these factors by giving constant training to them. These factors are explained below:

6.1 Attitudes:

Norman Maier states that an attitude is a kind of mental set, posture or bent. It represents a predisposition toward opinions. Suppose a worker is asked what he thinks about a guard on his machine or temperature, or lighting in his workroom, his reply is noticing but his opinion. The attitude is more general and influences his opinion. Knowledge of attitudes of workers helps the management to predict their opinions.

An attitude is a frame of reference, which affects our opinion of the objective fact. A change in attitudes may radically change opinions. Attitudes determine opinions and prejudices. Conservation and radicalism are two extreme kinds of attitudes. People with these differing attitudes have divergent opinions about the same facts. Disagreements about facts are also possible. Our various prejudices offer many illustrations of attitudes that determine the meanings, which facts may assume.

Attitudes reconcile contradictions. With the proper attitude as a background, intelligent people can reconcile others' contradiction. A clever and experienced Safety Officer or supervisor will reconcile contradictory opinions of workers and management about the efficacy of a particular safety device or a protective equipment, if he has knowledge of their attitudes. Such knowledge of attitudes helps him to find out the real cause of an accident.

Our loyalties and our prejudices are frequently in-group and out-group attitudes, respectively, and they provide sources of error in arriving at objectively sound conclusion. An attitude 'we are right and others wrong' has caused many accidents, and pose hindrances in solving problems.

Attitudes are usually associated with likes and dislikes and consequently have an emotional content. Our moods are temporary predisposition toward having certain emotional reactions. Our moods influence our attitudes. In one mood, a supervisor will fly into a rage at a worker's mistake, while in a different mood he may pass it off a something that could happen to anyone. Mood and attitude are difficult to differentiate. A mood is temporary and depends upon one's physiological condition such as poor health, loss of sleep, hunger etc. Emotional or psychological upsets influence one's physiological condition and produce moods, which predispose him to make unpleasant reactions.

The reason and argument may or may not influence attitude. Generally, a man defends his opinion and shows no readiness to change it even though his all points are answered. People prefer their wishes and desires and are not ready to be convinced by logic.

Personality differences determine the type of attitude. Some people are inclined toward radicalism, others toward conservatism, and still others avoid extremes. Likewise, differences in social dependability, decisiveness, emotionality, sex, intelligence and experience etc. influence attitudes on specific topics.

Various methods are used for measuring attitudes, and experimental findings are recorded.

Industry cannot afford to make radical changes, which will backfire. Use of attitude scales (devised by Thurston), opinion polls, suggestion boxes, interview method, safety committee etc. are industrial practices to know employee attitudes, grievances, suggestions, personnel counsellors etc. and thus to make it possible to prevent open violence or mass work stoppages.

6.2 Aptitudes:

Aptitude means inclination or fitness. Aptitudes are human characteristics or abilities related to the capacity to develop proficiency on specific jobs. These aptitudes can be grouped into five classes:

1. Mental abilities.
2. Mechanical and related abilities.
3. Psychomotor abilities.
4. Visual skills and
5. Other specialized aptitudes.

Various aptitudes tests are used in personnel selection and placement.

Mental ability means intelligence. The field of mental ability tests has been explored like other areas of testing. Some mental abilities are verbal comprehension, word fluency, memory, inductive reasoning, number facility, spatial visualisation and speed of perception. Thurston's studies suggest that primary mental ability can be measured by a test specifically designed for that ability.

Mechanical ability includes certain mechanical aspects, such as mechanical comprehension and the understanding of mechanical principles and these are motor or physical skills such as muscular co-ordination and dexterity. Thurston said it a complex of intellectual abilities.' Mechanical ability tests are used to select employees for jobs that require a mechanical 'knack' such as in the maintenance or setting up production machinery or in the repair of household appliances.

Psychomotor tests are used to measure muscular abilities or combinations of sensory and muscular abilities. The term 'psychomotor' includes dexterity, manipulative ability, motor ability and eye-hand coordination and other aspects of muscular performance. Various psychomotor ability factors have been identified such as control precision, multi-limb coordination, response orientation, reaction time, speed of arm movement, rate control, manual dexterity, finger dexterity, arm-hand steadiness, wrist-finger speed, aiming etc.

Every industrial job requires some degree of vision and many jobs require a high degree of skill in some particular visual function. Colour discrimination is also an important factor. Various vision tests are available. Mechanical and psychomoter abilities, visual skills and special aptitutes are essential for safety work.

Specialised aptitudes or attributes include the tests of clerical aptitude, reading speed, comprehension, vocabulary, perceptual speed etc.

6.3 Frustration:

Frustration means defeat or disappointment toward success. Any interference with the achievement of goal causes frustration. Characteristics of frustrated behaviour are suggestion, regression, fixation or resignation and it depends upon individual's tolerance, work pressure, situation etc. If a worker meets with an accident on a power press machine, he becomes nervous to operate it and this may result in repeating the accident. By providing the effective guard and explaining him about its proper use, his frustration can be gradually removed.

Frustration brings morale degradation, which in turn, increases accident rate.

A frustrated person responds in two ways:

1. Adaptive response i.e. acception of situation and substituted goal.
2. Maladaptive response i.e. the person may continue trying to reach the unattainable goal or he may give up trying to reach any goal whatsoever. He may show withdrawal response, attack response, limitation response or substitution response.' As propounded by Scott (1966) in his activation theory, human organism needs stimulation and variety in work. Environment without this motivation will suffer and frustration may result. Change or variety in job and stimulation may reduce frustration.

In industry there are many instances creating frustration. Not providing proper working conditions, tools, equipment and PPE despite of demand, not providing necessary guards and safety devices on machines and not giving promotion, increment, recognition and status as per requirement can cause frustration. All such dissatisfying factor should be detected in time and appropriate remedial measures including management functions should be adopted. Some situations leading to frustration and techniques of identification and management ar given in Table 3.3.

Table 3.3: Frustrating Situations and Remedial Measures

	Situation		Identification		Management
1	Increasing accidents to an individual	1	Check job or m/c condition.	1	Remove the defect.
		2	Check surrounding space, light etc.	2	Improve them.
		3	Study type of tool, equipment etc.	3	Use ergonomic design, standard tool, equipment etc.

		4 5	Study work method. Study his behaviour.	4 4	Correct it Employ psychologist and take his advice.
2	Work quantity (goal) excessive.	1 2	Study results, spoilage, effects of workload on body etc. Carry out time motion study.	1 2	Reduce the work reasonably (make the goal attainable). From the result, adjust the work, machine, tool etc.
3	Work quality is not obtained in spite of good efforts.	1 2	Check the material. Observe work method, machine, tool etc.	1 2	Have good quality material. Give training as required.
4	Worker becomes irregular, inattentive or reluctant etc.	1 2	Discuss with him or others to know the reasons Try to know family problems	1 2	Try to remove the reasons by giving more pay, promotion, making permanent etc. Try to solve such problems to the extent possible.
5	Monotony, fatigue etc. due to same type of work for a longer time and frustration due to that.	1 2	See the work speed or results. Ask the worker about his opinion.	1. 2.	Give change in job, place, department etc. to find new atmosphere. Give stimulation necessary.

6.4 Conflict:

Conflict means violent collision, a struggle or contest, a mental struggle etc. In industries conflicts of both the types - physical and mental - occur.

Conflict reduces productivity. Conflict may arise due to attitude, jealousy, bad behaviour, working condition / environment, power mongering, labour relation, favouritism etc.

To reduce conflicts, provide all necessary and better tools, equipment, guards, safety devices, safety clothing, protective equipment and welfare facilities for safe, healthy and satisfactory environment.

Conflict may occur between employer and contract workers if the later are not considered at par with the company employees in respect of providing safety equipment, training and other facilities. Therefore facilities of safely, health, welfare and working hours should be equally given to them.

Similarly safety committee meeting should not become a platform for conflicts. Safely is not a matter of dispute or conflict. Difference of opinion on any matters of safety should be settled by consulting experienced safety manager or consultant.

Some situations leading to conflict and techniques of identification and management are given in Table 3.4.

Table 3.4 : Situations of Conflict & Remedial Measures.

	Situation		Identification		Management
1	Supervisor (boss) favouring one group and disfavouring another group.	1 2	Try to find out labour unrest. Find difference in output of two groups.	1 2 3	Remove the reasons. Change supevisor if necessary. Explain Supervisor's a behaviour if he is justified.
2	Wage difference for same & similar type of work.	1 2 3	Labour unrest. Complaint. Litigation	1 2 3	Resolve by group discussion and dialogue. Give justification Attend properly.
3	Settlement with workers delayed.	1 2	Observe go slow, strike etc. Labour unrest.	1 2	Try to make settlement. Justify delay
4	Union rivalry.	1 2 3	Entry of new union and new demands. Workers' struggle. Effect on work.	1. 2. 3.	Justify right union. Take legal action. Settle the issues if possible.
5	Disciplinary action against worker (s)	1 2	The worker's reaction Support of other workers to him.	1. 2.	Justify before taking action and justify after action. Convince others.
6	Go slow, strike, Non-cooperation, Labour unrest.	1. 2.	Find reasons of dissatisfaction. Effect on work of efficiency.	1. 2.	Remove reasons. Provide safe / better tools, equipment, facility, condition etc.

6.5 Morale:

Morale is a mental condition in which both personal and group features are involved. Requirement of high morale, according to NRF Maier are (1) Individual's firm convictions and values which make life worth while and give energy and confidence to face the future (2) He must be aware of a job to be done to defend or extend his values and (3) His values must be in essential agreement with those of his group and there must be a co-ordination of effort in attaining objectives.

Guion has defined morale as 'the extent to which an individual's needs are satisfied and the extent to which the individual perceives that satisfaction as stemming from his total job situation.' This definition covers the personal aspect only, it does not cover the 'group' reaction aspect, which is also essential. G.W. Allport has defined national morale as an individual attitude in a group endeavour.

Thus the term morale signifies high values of life and a team spirit of a group, society or nation. The Indian concept stresses upon ethical values and loyalty, which gives high respect towards others.

Good morale is a resistance to frustration or defeat and poor morale is apathy or resignation.

Good working conditions are more conductive to good morale in industry. Type of supervisor and safety officer, ventilation and temperature, lighting and colour, guarded machinery, safe environment, sanitary and welfare facilities and attractiveness of the shop create an atmosphere which influences the morale of the workers.

Psychological factors influencing morale are mutual sacrifice, participation in-group activity, experience of progress toward a goal, tolerance and freedom within the group and confidence in leaders. These factors explain that morale is largely a social phenomenon and is subject to social influences. Morale in respect of an isolated individual requires high motivation, persistence and self-confidence.

In industry the morale of workers is influenced by –

1. Working conditions as mentioned above.
2. Behaviour of foreman, supervisor, safety officer and other leaders, with the workers.
3. Training programs (including motivation) for workers.

6.6 Fatigue, Boredom and Monotony:

These are another psychological factors affecting human behaviour.

Fatigue is defined in different ways:

It is a reduction in the ability to do work because of previous work - NRF Maier.

Decrease in the capacity to do work - a loss of efficiency.

Decrease in interest or willingness to work- a feeling of ennui or weariness - Starch.

More or less or complete loss of irritability and responsiveness of a tissue - Freeman.

Condition of mind resulting from prolonged mental activity - Wilson.

It is a failure to maintain physiological or organic equilibrium - Dill.

Thus fatigue is a physiological as well as psychological phenomenon. The evidence of physiological fatigue is found in muscle, nerve, blood and brain. It is measured by ergo-graph studies, which explain the nature of fatigue. Hourly accidents' and hourly production are used as a measure of industrial fatigue. Rest pauses, working hours and work shift have effect on fatigue.

Psychological fatigue denotes factors difficult to achieve, which cause work decrement. It includes the falling-off efficiency of work, which is commonly called as mental fatigue as well as boredom and monotony. Motivation can decrease fatigue. Improvement in environmental conditions such as workplace, workday, position, vibrations, training, job-change, water supply, clothing, food, sleep, rest pauses etc. can also decrease fatigue.

Boredom is another similar term with minute distinction as shown in Table 3.5:

Table 3.5 : Distinction between Fatigue & Boredom

	Fatigue	Boredom
1.	Physiological depletion	Mental dullness
2.	Decreases capacity for work.	Decreased interest in work.
3.	Conscious inability	Feeling of incapacity
4.	Result of too much work challenges	Result of absence of work challenges.
5.	Spirit is willing but the flesh in	Flesh is willing but the spirit is

	weak.	weak.
6.	Desire for rest	Desire for change.
7.	Somewhat measurable	Difficult to measure.

Repetition and monotony contribute to boredom.

Monotony is also a mental phenomenon affecting work. Monotony effects are more during the middle of the work period and disappear in anticipation of the end of the period. The extent of monotony depends upon repetitive nature of the task and degree of attention required.

Methods to eliminate boredom and monotony from industry are -

1. Exchanging jobs.
2. Relating the job to the larger picture.
3. The use of sub-goals.
4. The use of pacing methods and automatic work habits.
5. Rhythmical habit pattern. Piece-rate procedure.
6. Creation of favourable attitudes.
7. Improvement in working conditions and housekeeping.

6.7 The Problem Employee:

Some people think that 'Every human being is problematic. As every child in a home is a problem child, every employee is a problem employee.' Every addition of personality to an industry means increase in number of problems. Emotional and rational forces of workers create tense situations. This problem needs psychological study and solution.

Why an employee becomes a problem employee? The contributing factors are dissatisfaction of any type; foreman, supervisor and bosses of undesirable types, environmental factors and the employee himself.

Dissatisfaction may be due to many reasons lack of job security, irregular payment, less pay, breach of seniority rules, wrong works of superior, wrong favour, inactive shop committee, many promises without fulfilment, unwanted work changes, social unbalance etc. These should be removed.

Defects in foreman, supervisor and bosses are Incapable to manage others and to get co-operation from them, self-centred person, egoistic person, emotionally immature person, fault finding and bad tempered person improper regard for authority etc.

The environmental factors are partly due to the nature and attitude of co-workers and partly due to the physical conditions.

Maladjusted employees are - Unequal or superior to their task, persons with pronounced self-assertive tendencies, emotionally distinguished or immature persons, lacking in skill, ability and knowledge and lacking in job wisdom viz., insubordination, unreliability, absenteeism, laziness, trouble making, intoxicating, violation of rules, carelessness, fighting, misconduct, dishonesty, loafing or sleeping, dissatisfied, habitual loiterer, shopper, slow, agitator etc.

Fisher and Hanna have divided problem people in three groups:

1. The insane.
2. Disturbed by psychoneuroses such as paranoid personalities, inadequate personalities and emotionally unstable.

3. Milder forms of emotional turmoil. This group includes mostly the problem employees such as dissatisfied with their jobs, restless, absentminded, pessimistic, distractible, worrying unduly over minor details and unable to form decisions.

To discover problem employee, various equipment, tests, questionnaires and controlled interviews are suggested. It is advisable (particularly in the interest of safety) to discover such employees before their recruitment. Subsequent finding will create problem, as it may be difficult to remove them because of legal, union and other reasons. Subsequent remedy is to care and train them.

7. INDIVIDUAL DIFFERENCES

It is a matter of common experience that people differ from one another. Their physical appearance and traits such as height, strength, intelligence, ability of work, memory, speed of reacting a signal, honesty or emotional stability and mental traits, personality traits, sensory capacities, muscular co-ordination etc. are some of the factors of individual differences.

7.1 Classification of Differences:

Joseph Tiffin and Ernest McCormick have classified individual differences in work performance due to following variables:

1. **Individual Variables** (Human Factors): Aptitudes, personality characteristics, physical characteristics, interest and motivation, age and other personal variables.

2. **Situational Variables** (Environmental Factors) : subdivided as
   (A) Workplace variables: Physical environment, workspace and arrangement, design and condition of work equipment and methods of work.
   (B) Organisational and social variables: Character of the organisation, type of training and supervision, type of incentives and social environment.

Psychologists have tried to determine the ultimate cause of individual differences among people. They have shown two general categories of. heredity and environment. Generally the people are influenced by the combined effect. Heredity has more effect on height, weight, strength and appearance. Environmental factors have dominant effect on personality traits and interests.

7.2 Perception of Danger & Risk:

Different persons have different degree of perception of danger and risk. Due to individual differences capacity of understanding and identifying the hazard differs. While crossing highway, one person may have correct judgment of chances of accident looking to the distance and speed of the vehicles coming from sides. Different workers have difference of opinion or judgment regarding-hazard arising out of moving machinery or risk from chemicals.

Danger and risk are defined in pera3.14 and 3.75 respectively of Chapter 2. Important is the response time required for quick action to protect our self or others from the danger or risk. Slow response time indicates more chances of accidents and vice-versa. Safety training can help to improve ability of good perception of danger and risk and help to minimize accidents. Some examples of perception of risk is given in the following table:

Examples of perception of Risk.

Sr.	Hazard	Risk	
		Chance, Frequency or Probability	Severity or Consequence
1	Banana skin lying on the road	2 persons falling on the road out of 100 persons passing per hour. Risk = 2 x 10^{-2} per hour.	1 person gets head injury. 1 person gets leg injury.
2	Broken ladder	4 persons falling from the ladder out of 100 person using it per week. Risk = 4 x 10^{-3} per week.	1 person gets head injury. 1 person gets hand injury. 1 person gets leg injury. 1 person gets waist injury.
3	Running pulley belt without guard	2 workers fingers being trapped out of 30 workers per month. Risk = 2/3 x 10^{-1} = 0.666 x 10^{-1} per week.	1 worker gets crush injury. 1 workers suffers amputation of finger.
4	Platform without railing at height	1 person falling from height out of 1000 persons going there per year. Risk = 1 x 10^{-3} per year.	He dies.
5	Open or loose electric wiring.	1 person getting electric shock out of 10 persons per month. Risk = 1 x 10^{-1} per month.	Heart failure

7.3 Differences affecting Safety performance:

Human factors contributing to accidents are stated in Part 5. They affect safety performance as follows:

(1) Physiological Factors: Physiological human factors are physiological fitness (safe capacity) of an individual estimated from his maximum oxygen uptake capacity, sex, body-build, age, muscular work, posture, clothing, nutrition, training and skill, sickness or disease, environmental heat load (strain), occupational work load and physiological fatigue measured by 'step test'. See Part 2 of Chapter 24 also.

A worker who is physically fit performs well and less susceptible to accidents. Tough task requires more physical (muscular) work, which in turn, demands more oxygen uptake capacity. Test of physical fitness 'is necessary to select a person for accident prevention.

A man can lift more weight than a woman due to sex difference. An adult can lift more weight than a child due to age difference. A man with powerful muscles does more work than that of poor muscular power. A tall man walks faster than a short man. A fat man runs slower than a thin man. Height, body, hands, arms, feet, vision (eyes), hearing (ears) and other postures and traits create individual differences in men and in their performance for safety.

Good nutrition, training and skill increase work capacity and power of performance for safety. Sick man or man with disease has more susceptibility to accidents. High room or process temperature, higher quantity of work and physical fatigue certainly contribute to accidents.

(2) Psychological Factors: Psychological human factors are attitude, aptitude, frustration, conflict, morale, motivation, boredom, monotony, accident proneness, mental capacity and skill, senses, memory, mental fatigue, mental blocks, perception of danger, acceptance of risk, knowledge and responsibility for safety, judgement of mind, impulsiveness, ability to pay attention on machines, tools or hazards, nervousness, fear, carelessness, emotional stability, intelligence, previous experience, vocational interest etc. Difference of these factors in person causes individual differences and affects their work and safety performance. Explanation to some of these factors is already given in foregoing paragraphs. Some more examples of psychological factors are given below:

Sensory motor ability i.e. clumsiness, slowness of motor impulses, defective sense organs, inadequate skill etc. are causative factors for accident. A study of over 600 employees for their sensory motor test, showed that poor test scorers had 48% more accidents than those of high scorers.

Perceptual good ability i.e. to perceive many details of a visual field or to see and understand quickly from a far distance is useful to prevent a person from danger or risk. Harano's research work on drivers proved this fact. If a man cannot see danger or risk while working with chemicals or dangerous machines, he may attract accident. If he understands and accepts the situation as a risk, he will be conscious and more careful, may check safety device or use safety equipment and may avoid accident.

Knowledge (which has no substitute) of unsafe conditions, actions and safe practices makes a man less susceptible to accidents. Information, education and training of safety subjects increase safety knowledge, which helps for safer performance. That is why safety information and training to workers (i.e. their knowledge building) are made statutory under the Factories Act, 1948.

Responsibility creates awareness and sense of duty to perform task given to us. Supervisors, Safety Officers and other responsible persons feel their safety duty to increase their safety performance. There fore policy of promotion to increase responsibility is necessary for better efficiency of work

Emotional instability or maladjustment or more than normal ups and downs in moods may cause more accidents. Such state of mind may result in frustration, conflict, carelessness or negligence ultimately resulting in accident.

Frustration i.e. aggression, regression, unfraindly, withdrawal, imagination, intoxication may make a person accident susceptible. Therefore his level of frustration should be kept under control.

Work experience helps in avoidance of accidents. Vernon and Van Zeits's studies shown that the accident rate was declined due to increase in work experience. New employees are more susceptible to accidents than old (experienced) ones. Higher age adds more experience, wisdom, maturity and stability. Therefore aged employees cause less accident than young ones.

(3) Physical Situational Factors: They are physical workload and stress, working hours, work design, tool and equipment design, hazardous nature and pollution of chemicals i.e. splashes, spillage, gases, dusts, fumes, vapours etc. directly connected with the work, nature of job and ergonomic factors.

If above situations are inconvenient or injurious to health or polluting atmosphere, they may lead to accidents, dangers or risks.

Daily effects of chemicals on workers' health, though it is not termed as an reportable accident (because not resulting in absenteeism), is worse than an accident and certainly needs safety measures.

Awkward position or situation of seat, operating valves, gauges, platforms, tools, equipment etc. cause unnecessary strain on worker's body and may cause accidents. Therefore they should be redesigned to suit the workers (ergonomics) to avoid such accidents.

Long working hours, work without rest intervals, excessive weight, glare or excessive light from welding, dust generating process etc. result in accident. They should be regulated as per the Factories Act.

(4) Environmental Factor's: They are temperature, ventilation, light, noise, vibration, humidity, thermal or nuclear radiation, poor housekeeping etc. and acts 'of God.

It is also experienced that too hot or too cold temperature, high wind velocity, high noise, vibration, darkness, humidity, radiation etc., cause accidents, and good light, colour/music, temperature/ventilation and good housekeeping tend to reduce them.

Psychological Tests: Various psychological tests have been developed and applied to detect above mentioned factors and their correction.

Mental ability test, mechanical ability and related test, psychomotor test, vision test, special aptitude test, personality and interest test, achievement test, merit rating, measurement of training, attitude scales, intelligence or IQ test, skill and manipulative test, trade mill test and computer based assessment methods etc., are described in many books of industrial psychology. Old book of Joseph Tiffin & Ernest McCormick and new book of Lewis Aiken are worth mentioning for such psychological testing and assessment.

To control effects of individual differences, some control techniques are as under:

7.4 Accident Proneness:

This debatable belief is discussed below. 7.4.1 Concept of Accident-proneness

Accident proneness can be defined as a higher than average susceptibility to accident, which arises from psychological factors-and tends to be permanent, if not cured timely.

Old theory of accident proneness or accidents susceptibility is derived from many accident case studies and *Personal Factors* for its causation. Age, sex and experience, emotional instability, physical condition, use of alcohol and attitude toward organisation are main factors. Other factors such as height, weight, eye sight, marital status, number of dependants, distance and method of travel to work, medical history, demotivation, talkativeness, neurotics, smoking, loneliness, less interest, domestic stress, temperament etc., may also provide ground for accident proneness.

Greenwood and Woods presented this premise in 1919 in their paper on Industrial fatigue. It was also supported by some old psychological studies, but their "so called statistical proofs' are criticised as deceptive based on inadequate samples or the result of highly subjective diagnosis. The later studies do not accept this concept of 'accident proneness or accident repeater' and suggest throwing of it.

According to this old concept, some people are so constituted that their very nature (above mentioned personal factors) causes them to bring about accidents and so to injure themselves and others. Such individuals are known as accident-prone or accident susceptible persons. People differ in degree to which they are accident-prone in the same way that they differ with respect to their traits. Accident-prone persons are not necessarily accident repeaters. They may or may not repeat the accident depending upon their learning, experience, training and improvement in health, habits, environment and other personal factors. Accident-prone people do not mean a fixed group responsible for all accidents every .time. Accident proneness is a variable qualitative factor and any man can be accident-prone at any time depending upon personal factor developed in him.

7.4.2 Is it Myth (false belief) or Reality?

C.A. Drake's study in 1940 on accident proneness concluded that the person who reacts quicker than he can perceive is more likely to have accidents than is the person who can perceive quicker than he can react. Farmers & Chambers and Speroff and Kerr also conducted tests but for different jobs.

It should be emphasised that the personal variables that contribute to accident proneness on one job may be unique to that job only. Factor(s) for work situation may differ and it can be identified by specific statistical analysis for that situation.

Many people do not cause any accident for years together. It is a small percentage of accident-prone workers who are responsible for personally caused accidents. This does not mean others do not cause accidents. Proof of this fact is given in a number of studies by Slocomb, Greenwood and Woods, Karl Marbem, Bristol, Snow, Bingham and t)e Silva.

Various tests and clinical approaches are suggested for accident proneness. Such studies have recorded many contributing factors to accident proneness. In addition to personal factors mentioned above, other factors are- inability to concentrate, incapacity to distribute attention, slow reaction time, absentminded-ness, fatigue, reduced energy, inadequate control of reflexes, poor judgement, poor sensory-motor co-ordination, unacceptable behaviour, oscillation of attention, hurry, worry, fear, nervousness, impulsiveness, excitement, eager & enthusiastic, thoughtlessness, overconfidence or any combination of these traits.

Based on above facts and findings, it can be said that accident-proneness is a reality to some extent and not a mere myth. If we call it a myth then what should we call the reality of all above actual human causes and accidents actually happened (and happening) due to them? And accid ent causing by the same persons under the same working conditions where others do not cause any accident? Accident proneness is a name given to a psychological and scientific-study of human behaviour in accident causation.

Viteles mentioned 'circumstances' responsible for more accidents to some persons. Such circumstances could be worry, anger, fear, guilt feeling or other emotional disturbances.

Hale and Hale pointed out that there cannot be any stable personality trait like 'accident proneness'. Some studies revealed that 'members of a study group who sustained a large number of accidents in one period, were not necessarily same who sustained many accidents in a subsequent period.

But it is also a fact that there are persons who have more accidents than other persons in similar situations. However the repeaters are involved in only 15-20 percent of all accidents. Therefore another view prevails telling it a myth. Believers of this view tell that there is nothing like accident-proneness and all accidents are due to working conditions or impersonal factors only and if we can remove all such unsafe conditions there shall be no accident. System safety approach is important in this regard. A man is compelled by conditions to cause mistake or accident and therefore, instead of blaming the human faults or fate; we should concentrate upon to remove the real unsafe condition, situation or environment only. It is true that we must first remove the unsafe conditions, but, what are the reasons that under the same working condition some people make accidents and others not? Can these 'some people making accidents in the same working-conditions' be called accident-prone or not? This replies the question whether accident proneness is a myth or reality.

Dr. Schulzinger and Professor Edwin E Chiselli ruled out the concept of accident-proneness and stress that the proportion of accident-prone people in any group is so negligible as to be quite unimportant in safety work. Professor Edwin says, "The term accident proneness should never be used in safety work or in studies of the causes of accidents and injuries, as it is dangerous, misleading and contributes nothing of practical value to our understanding of industrial accidents and injuries." M.S. Schulzinger's study of 35000 injury cases indicates that the 'injury repeated is not a significant factor in the safety programme.

A leading industrial psychologist Maier says that it is doubtful that a single set of such bio-psychological traits (accident proneness) alone can cause accidents.

Mintz and Blum found that the frequency of repeater injury approximated a pure chance distribution.

7.4.3 A Complex Phenomenon:

Main reason of accident proneness is the individual differences. Nobody wishes accidents, but personal factors do contribute to accidents. Ill health, tension, worry, hurry, lack of concentration and lack of training do cause many accidents. Therefore accident proneness may be regarded as a combination of personal factors, which make a person highly proficient in bringing about accidents. It may be dependent on a rather complex set of traits and these traits need not be the same for all accident-prone individuals. However, if accident-proneness is to have any application to industry, it is necessary to determine the traits, which are associated with accident susceptibility and to develop tests for detecting their presence. Obviously, accidents can be reduced if accident-prone individuals are kept out of hazardous work. In this way the safety of others, as well as that of themselves, will be increased.

Some measures to reduce accident proneness are-

1 Proper selection and placement of employees.
2 Safe-guarding, training and supervision of inexperienced employees.
3 Use of safety and personal protective equipment and
4 Immediate attention to injury and care.

The harm caused by the concept of accident proneness, the new tests overruling this old concept and the real philosophy, are already explained in Part 5 of Chapter-2.

In modern age and modern plants, the concept of accident proneness is hardly accepted. It seems outdated. Modern accident analysis does not accept it and report it Modern safety philosophy puts more stress on detection and removal of unsafe conditions and training for safe actions. However psychologists while studying human failure as an accident cause may refer to such concept.

8. MOTIVATION FOR SAFETY

8.1 Need (Purpose) of Motivation:

Motivation includes inspiration, aspiration, communication, education, participation and training. All these factors are most essential to mould a man to achieve a desired goal in a desired manner. It is a fuel or driving force for all human activities, which should be refined, channelled, rectified, shaped or directed as per requirement. To minimise the human errors or unsafe acts or omissions, motivation helps much and it promotes safety.

If people are not motivated for safety, other efforts will not help much. Even if other measures are taken, motivation is necessary to mould the. people to achieve our goals more speedily and yet safely. Various theories are available for motivating people for work. Periodical feedback to maintain motivation is also necessary.

Our present problem is not of lack of knowledge of safety. The real problem is of implementation of that knowledge, at the shop floor level. This is because of the lack of self-motivation, lack of communication and motivation. People should be made participative by inviting them to say their opinion, reaction or views and guided to act for implementing the safety. Direct communication is more useful than indirect communication. Thus communication and motivation helps in implementing the safety laws.

Formula of Performance = Ability X Motivation, explains basic need of motivation to increase or improve the work performance of individual or group.

Total loss control can be achieved by motivation of employers, employees, trade unions and the Government. Losses of time, money, property and production because of accidents, conflicts etc., must be reduced and that is possible by motivation at all fronts.

8.2 Nature of Motivation:

Motivation is one of the factors that stimulates or influences job performance. A Latin word "mover' means to move. A motive is what moves a person or impels a person. Motivation is concerned with 'Why' and "How' of behaviour.

P,T. Young defined motivation as "the process of arousing action, sustaining the activity in progress and regularising the pattern of activity." .

Steers & Porter and Greenberg & Baron identified 3 major components of motivation:

1. Force or drive to lead to some behaviour.
2. Function to guide behaviour in desired direction and
3. Maintaining or sustaining behaviour once it has occurred.

Herbert Moore says 'To motivate is to cause a release of energy in relation to a desired goal. Effective motivation is determined by three factors: the goal that is to be realised, the energy that is to be released and the tools that are to be used to direct and control that energy. The Whole problem of motivation is the problem of the development of attitudes, loyalties and capacities for making sacrifices toward an entity that is of greater consequence to the individual worker than his job or •his personal welfare.'

Motivation runs top to bottom, therefore the top management and supervisors should be motivated first. Motivation should be self generated, otherwise it should be supplied or induced.

NRF Maier explains motivating as a way of bringing to expression an ability, which a person already possesses. He describes two aspects: subjective and objective. The subjective side is a condition in the individual, which is called a need, a drive or a desire. The objective side is an object outside the individual, which may be called the incentive or goal. When an incentive satisfies the need (as food satisfies hunger or money satisfies economic need), the situation is called motivating. The types of needs and incentives vary from time to time and from person to person. It is an industrial problem to find out needs and their appropriate incentives. This is explained below.

8.3 Theories of Motivation:

Some 'psychological theories are developed to motivate people to improve their performance. These theories are based on varieties of needs and, their satisfaction (incentives or rewards).

8.3.1 Hawthorne Studies (Behavioural Approach):

In an old study conducted at the Hawthorne works of the Western Electric Company, Chicago for 15 years, beginning in 1924, concluded that the attitudes of employees could be significantly changed by the development of a co-operative atmosphere between workers and supervisors.

Change in temperature, humidity, lighting, rest pauses and length of workday have little effect if the employees are well motivated with friendly, social and co-operative relations. Thus motivation has more effect than the improvement in working conditions. If a good confidence is generated in people, they can work hard for their company.

Success of Japanese management seems relied on this theory. Motivated soldiers have won many battles with inferior weapons and being less in number. See part 8.2.4 of Chapter-6.

On power-press machines, workers mostly injure their fingers and get demoralised if the frequency rate is not reduced. Here a supervisor can play an important role by standing near the worker, explaining and training him for pre-start safety •devices, guarding on machine and safe work method, thus giving special attention, co-operation and building confidence in the worker to work accident free.

If workers receive personal touch i.e. special attention for their safety, health and welfare by upper management, they get motivated to give more production even if working conditions like light, space, layout etc. are not fully favourable. This is the abstract of this oldest study.

8.3.2 Maslow's and McGregor's Hierarchy Theory of Human Needs; (Need Satisfaction for Safe Performance)

A.H. Maslow classified the human needs and determined priorities for them. These needs should be satisfied in the following order.

1. **Physiological needs:** Basic or survival needs of food, water, air and rest.

2. **Safety needs:** Protection against danger, threat and deprivation, body and position or status. Reduction of physical and psychological hazards.

3. **Social or Affiliation needs:** Love, affection, friendship, acceptance, association and belongingness.

4. **Ego or Esteem needs:** Two types - (a) Relating to one's self-esteem i.e. needs for self-confidence, achievement, competence and knowledge (b) Relating to one's reputation i.e. needs for status, recognition, appreciation and respect of one's fellows.

5. **Self-fulfilment needs:** Relating to one's own potentialities, for continual self-development or self-actualisation.

This theory helps management to detect needs of their people and to satisfy them priority wise for better or safe performance. Providing safety goggles to welder, grinder etc., giving mask/respirator/hand gloves/aprons etc., to chemical workers and to provide ear plugs to weavers working on high-noise looms, fulfil safety needs of the workers and motivate them for safety. Then after they need love and affection. The steps of this theory can be shown as under:

Human needs → Detection → Satisfaction → Incentive or Reward → Feedback for improved performance → Rethinking of type of satisfaction or incentive, if necessary.

Hierarchy of human needs in this theory can be shown as under:

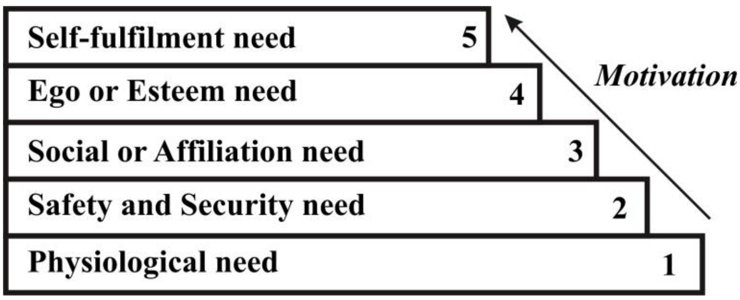

Fig 3.2. Hierarchy of Human Needs

First need should be satisfied first, then second, then third etc. If person is already satisfied with the first need of food, water, rest etc., beginning should be made with the second need and so on.

Maslow's theory was criticised by W. Bridewell, Luthans, Hall & Naligam (1968), Walba & Bridewell and surveys in Japan and European countries raising more questions against such needs and their satisfaction.

However it should be noted that Maslow's research work is some 50 years old and represents priority of needs of that time. Owing to improved standard of living and many changes during last 50 years, priorities have been changed and may continue to change. Effects of liberalization, privatization and globalisation (LPG), decrease in trade union activities and increase in unemployment can bring new challenges and new needs, nevertheless Maslow's needs still seem important and are useful for motivation.

Our Indian concept is to minimise the human needs for real happiness but how to implement it for industrial workers is a psychological problem. Self motivation and satisfaction seems to be the best remedy.

8.3.3 ERG Theory:

Clayton Alderson offered this theory in 1969 based on needs of Existence, Relatedness and Growth (ERG). His theory is an improvement over Maslow's theory.

Existence needs are basic needs of food, clothing, shelter etc., and management can satisfy them by pay, allowances, better working conditions, job security etc.
Relatedness needs are affiliation and esteem needs.

Growth needs are self-actualisation need stated by Maslow.

By knowing needs of the workers if management takes necessary action to feed those needs, the workers can be motivated for better performance.

Suppose some workers do not take part in Safety Committee because of their belief that they know little about industrial safety. If knowing this need of knowledge, they are given proper training for safety; they will be motivated to participate in Safety Committee.

8.3.4 Herzberg's and Myer's Theory

(Motivation - Hygiene Theory):

Frederick Herzberg and his followers - Schwartz, Jenusaitis, Stark and Myers, carried out various studies on motivating factors. Herzberg and his team interviewed 1500 workers for 12 types of investigation to know what were the satisfying factors and what were the dissatisfying factors with their reasons. From this extensive study, some more important factors are given below:

Occupational Group	Satisfiers	Dis-satisfiers
Scientists	Work itself	Responsibility
Engineers	Advancement Work itself	Responsibility, Company Policy and Administration
Supervisors	Advancement Responsibility	Pay

Technicians	Advancement Responsibility	Work itself, Pay
Female assemblers	Supervision	Recognition, Security

Another study points out motivation needs and maintenance needs as follows:

Motivation Needs (Intrinsic Factors) : These are the factors of growth, achievement, responsibility and recognition such as delegation, access to information, freedom to act, atmosphere of approval, merit increases, discretionary awards, profit sharing, company growth, promotions, transfers and rotations, education, memberships, involvement, goal-setting, planning, problem solving, work simplification, performance appraisal, utilised aptitudes, work itself, invention & publication.

An effective intrinsic motivation technique is job enrichment, which includes

1. Making employees responsible for the total function or completion of a task instead of breaking it into assembly line specialisation.
2. Allowing employees to both start and complete a project or task.
3. Diversification of duties so that no one has all of a boring task (there should be interesting parts in all jobs).
4. Delegation-decision making down the hierarchy as much as possible and
5. Conducting rotating job assignments.

Maintenance Needs (Hygiene or Extrinsic or Environmental Factors): These are the factors classified as below

1. **Physical:** Work layout, job demands, work rules, equipment, location, grounds, parking facilities, rest rooms, temperature, ventilation, lighting, noise.

2. **Social:** Work groups, coffee groups, lunch groups, social groups, office parties, ride pools, outings, sports, professional groups, interest groups.

3. **Economic:** Wages and salaries, automatic increases, profit sharing, social security, workmen's compensation, retirement benefit, paid leave, insurance, tuition, discounts.

4. **Security:** Fairness, consistency, reassurance, friendliness, seniority rights, grievance procedure.

5. **Orientation:** Job instruction, work rules, group meetings, shoptalk, newspaper, bulletins, handbooks, letters, bulletin boards.

6. **Status:** Job classification, title, furnishings, location, privileges, relationships, company status.

Neither intrinsic nor extrinsic rewards give a complete motivational package. The factors vary according to person and atmosphere. Therefore selection of proper reward is a tough job.

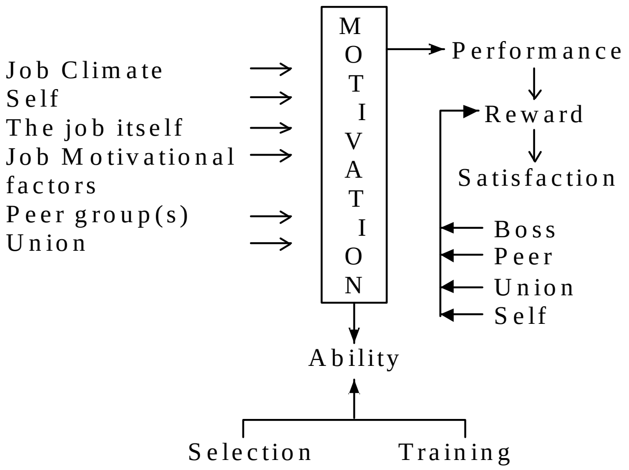
Complete elimination of dis-satisfiers does not give positive satisfaction or motivation. To inspire motivation, satisfiers are to be provided.

To explain and to give (display) in writing safe operating procedure to workers and to provide fixed guard on cutters, fulfil physical needs of the workers. Promoting a Safety Officer on higher post, considering his length of service and performance, fulfils his need of status. Such steps do motivate them.

All top management, supervisors and safety advisors must believe that better psychological working conditions (stated above) can help to improve the life and cooperation of the workers.

8.3.5 Peterson's Behaviour Model (Motivation-Reward-Satisfaction Model):

Peterson has developed a model, of motivation and performance as under-



Here safety performance is dependent upon level of motivation and his ability to perform. Motivation depends on job climate (by boss-style, staff-climate, management-relations), self (personality achievement), the job itself, job motivational factors, his peer group (norms established and performed) and by the union (norms and pressures). Ability depends upon selection (can he do it?) and training (does he know how?).

Following performance there are all kinds of rewards (positive and negative), which influence his level of satisfaction. The' rewards come from the boss, peer groups, union and self. Upon receiving these rewards he then compares the reward received to what he expected to receive and is either satisfied or dissatisfied to a degree, which influences (feed back loop) whether or not he shall be motivated enough to perform again.

8.3.6 Vroom's Valance or Expectancy Theory:

It is also known as 'instrumentality theory or process theory'. Historically it goes back to Tolman (1932), Lewin '(1938) and Peak (1955) but Vroom's version of this .theory introduced it to industrial psychology and that of Porter & Lawer (1968) emphasised on 'How' instead of 'What' of motivation.

Outcomes like salary, security, recognition etc. have different values (attractiveness) for different people. Motivation according to this theory is a product of valance (desire), expectancy and instrumentality.

Valance is the attractiveness of a goal or outcome. It has two propositions: (1) The desire (Valance) for any particular objective (outcome) on the part of an individual is directly related to the likelihood that the objective will in turn lead to other subsequent objectives of given desirability and (2) The greater the valance of any outcome, the more quick is a person to take action.

In Vroom's theory, money acquires valance due to its perceived instrumentality for obtaining other desired outcomes i.e. its power of exchange or purchase.

The abstract of the theory is that the linkage between behaviour and reward should be declared in advance, the linkage should be implemented and reward should be given every time when a desired behaviour is achieved. This looks like a conditional motivation.

For example, if promotion or pay-rise (valance or attractiveness of the goal, outcome or reward) is declared for certain target (desired performance) and if a worker feels it achievable (expectancy perception), he will be motivated to engage in performing to achieve that target. On performance, declared reward should be given to him.

By providing better comfort by ergonomic design of machines, tools, equipment, controls etc., and reward for safety attitude and effort, management can generate desire in workers for safe performance.

8.3.7 Magregor's X & Y theory:

Magregor developed this theory, which has two parts - theory 'X' and theory 'Y'.

Theory 'Y' is more useful to develop safety culture by motivation.

Theory X Normal, conventional or old views regarding human behaviour-		**Theory Y** Modern or correct views regarding human behaviour -	
1.	An average worker has inherent dislike of work and will avoid it if he can.	1.	An average worker does not inherently dislike the work.
2.	An average worker prefers direction, wishes to avoid responsibility, has relatively little ambition and wants security above all.	2.	An average worker learns not only to accept, but also to sick responsibility under proper conditions.
3.	Workers must be corrected, controlled, directed, threatened or punished to achieve objectives.	3.	Self-control and self-directive are preferred by the workers to achieve objectives.

8.3.8 Goal-setting Theory:

Rayon (1970) put more stress on 'intention' to motivate behaviour. Locke & Latham (1990) supported this theory explaining to set goals to motivate people to show their ability (efficiency). Research studies by Miller (1978), Latham & Locke (1979) showed that performance could be improved by setting 'specific goals' and not the general goal like 'do your best'.

Reward for zero accident goal, accident free month, year or department, good housekeeping and a fixed target and guidelines motivate workers to attain them. Goals should not be too easy or too difficult. Moderately difficult goals pose a challenge to an individual and impose the commitment. Steady & Ka/s study (1964) showed that goals, which were perceived as difficult but attainable, led to increased performance than goals, which were easy or impossible to achieve.

Workers should be involved in goal setting process instead of assigning goals by others. Workers' understanding and appreciating of goals are necessary. Latham and Saari's study (1979) showed that it becomes easy to achieve difficult goals through supervisory support. Chhokar and Wallin's study (1984) to improve safety performance showed that 'feedback to workers how to reach the goal' found useful and percentage of workers working with safety precaution was raised from 65% to 95%.

Feedback improves individual as well as group performance. In Britchard, et al (1988) study, group performance showed 75% improvement by group goal setting and feedback. Northcraft, Lee and Lituсy (1990) pointed out two types of feedback - outcome feedback and process feedback. Outcome feedback provides information about consequences of one's actions and process feedback about ways to improve task performance.

Zero accidents goal by NASA (USA) is the best example of this theory. In some Tata Companies, incentives to all workers of a department where no accident occurs during a month, motivated the workers. Supervisors were giving guidance to their workers to achieve the goal for their department.

Summary: Psychological principles discussed in all above theories suggest-various means and ways for management (including supervisors and safety officers) to motivate people for safety and to identify situations leading to conflict, frustration, non-co-operation etc., and techniques to remove them. For further techniques see Chapter-6 on Safety Management.

8.4 Methods of Motivation (Incentives or Rewards) :

While discussing nature of motivation, we have seen that there are human needs, drives or desires (explained by various theories) which- should be satisfied by necessary incentives or rewards for the purpose of motivation. Various methods are available to apply these incentive schemes. Some are given below:

(A) Money as an incentive: Money, in itself has no incentive value. But it can be used to obtain the desired incentives, because of its exchange power or value. Money can satisfy (1) Basic necessities of life (food, shelter, clothes and the like) (2) Necessities for health and education (doctors, choice of foods and so on) (3) Luxuries (mostly acquired needs) (4) Social position and (5) Power. If first need is satisfied men want money for second and so on.

Various methods of pay are applied according to the need or nature of job. Pay in terms of production, time, seniority, need etc., are in practice. Pay in terms of production (work output) is the only method, which utilises pay for motivating all men to produce in accordance with their abilities. But only money cannot satisfy all needs and other methods of motivation are as follows.

(B) Work and Play: Men should learn to play while they are still young, so that this activity can replace work when the latter becomes too strenuous for their energies.

(C) Use of Praise as an incentive: Praise is a form of ego satisfaction, and adults and children can readily be motivated by it.

(D) Competition: It is a motivating factor and highly effective in sports and safety. It can be used in work and it transforms unpleasant work into a game. Competition between equals produces better motivating conditions then competition between unequal in ability.

To promote and maintain safety, various types of safety competitions should be arranged viz., good housekeeping, accident free man-hours worked, production quantity and quality with safe performance, better maintenance of machines, stores, plant and premises, safety slogans, posters, maxims, essays, awards of various kinds etc.

(E) Other Incentives: Among other incentives more important are job security, compensation, opportunities for promotion and advancement, employee financial benefits (insurance and so forth) and informing employees about their job status.

Various studies have been carried out to find out factors of job satisfaction in different occupational groups, by Chant, Wyatt, Berdie, Blum and Russ, Jurgensen and others and many factors (workers' wants) have been recorded. High pay was found to be only at sixth or seventh in importance. Rank positions of such factors that appeal to workers are : opportunity for advancement, steady work, opportunity to use your ideas, opportunity to learn a job, good boss, high pay, opportunity to be of public service, good working companions, comfortable working conditions, good working hours, clean work and easy work. Other factors like benefits, communications and recognition also exist.

Incentives are classified as financial and non-financial, competitive and co-operative. Though money has not lost its importance, non-financial and cooperative incentives are more preferred in these days both in industrial and educational context But for poor people money will remain a powerful incentive forever.

See Part 11.3.5 & 11.3.6 of Chapter-6 for safety competitions and incentive schemes. See Part 8.2.5(2) of Chapter-4 for 10 methods to create and maintain individual interest.

Workers have three types of relations (social system) according to Bray Field and Crockett: (i) with fellow workers (ii) within company structure and (iii) outside the company. Motivation is a function of all these systems.

8.5 Role of Safety Management in Motivation:

Role of Management, Supervisors and Safety Department in motivation is most important. They should adopt following measures:

1. Insist for adequate sensory motor abilities, appropriate muscular perceptual speed or right perceptual style, free from accident proneness, disease and habit of intoxication, appropriate age, sex, experience, work habits and good safety record.

2. By induction training' new workers (including contract workers) should be given necessary safety instruction and training regarding hazards and control measures in industry. This basic knowledge will build confidence.

3. Schedule for above training should be properly designed to include hazards of raw materials and processes, safe operating procedures, safety tools and equipment to be used, safety work permit systems, interpretation of MSDS, labels, signs & signals, rules of transportation, loading and unloading and role of the workers in fire fighting and operation of On-site Emergency Plan.
4. Company's Safety & Health policy. Environment policy and Quality policy should be explained with their objectives and benefits. Organizational interests should be explained. This will bring belongingness and togetherness.

5. Workers should be encouraged to participate in safety committee, safety suggestions and all safety programmes.

6. Accident case studies should be explained at all levels by analysing the different roles in preventing such accidents. See Chapter-30.

7. Motivating thoughts as given in next part 8.8 should be explained with examples. These will help much for motivation.

8. Team spirit and competitiveness should be built-up. This will induct group motivation.

9. Supervisors should take sufficient rounds to them if any unsafe practice is noticed. For good work and follow up of safely rules, they should praise the workers. Safe habits should be cultivated.

10. Proper attention should be paid for basic needs of Health, Safety and Welfare facilities under the Factories Act and Rules for the workers.

Keep good housekeeping, lighting, ventilation and temperature. Avoid overcrowding, faulty arrangement of materials, machines etc. Provide sufficient means of access, right tools and equipment. Prevent leakage, pollution, noise, vibration etc., by good engineering controls.

Excessive workload, working hours, overtime work or work on holidays should be avoided or minimised. Sufficient rest intervals should be given. Statutory provisions shall be followed. This will prevent physical and mental fatigue, frustration, conflict etc.

11. Exploitation of any kind should be avoided. Paying less wages (less than even minimum prescribed by law) to the workers, not paying in time, not paying according to his qualification and experience or reasonable living standard, not paying overtime wages for extra work, requiring regularly to work 12 hours instead of 8 hours in a shift, depriving of holidays, treating unequally among equals/partiality in giving benefits, not implementing any legal order in favour of workers and indirect harassment to leave job are some instances of exploitation. Top management should leave 'them if it desires motivated workforce for better performance.

12. Supervisors should recommend or the top management should take timely decision to give increment, promotion and other monetary benefits to the workers.

13. Job rotation or job enrichment should be practised as a technique of motivation as 'explained in Herzberg's theory. It should include proper job distribution, job simplification and job satisfaction.

14. Introduce change in job if monotony is observed. Make the job meaningful to develop interest in it. Take workers in confidence to fulfil goals. Provide welfare and recreational facilities. Give responsibility and reduce interruption of work. Use colour and music where appropriate. Consult psychologist for special psychological measures to increase worker's interest and .efficiency by change in their behaviour.

15. Insist for man-machine matching i.e. designing machines, tools, equipment, controls and situations most convenient to people at work. This can reduce accidents. See Part 3 of Chapter24 for details.

16. Opportunity of advancement for R&D work, new product, new market, new safety device, diversification and delegation of more powers should be given to the deserving workers.

17. Bureaucratic or dictatorial behaviour retards motivation. Therefore middle and to management should be cautioned for this negative factor and they should be instructed to observe flexibility, love, affection, sympathy an good respect to workers.

18. Annual work assessment report (as CR in Govt for individual employee should not be written with any bias or by misusing the power. This will certainly de-motivate the worker. It should be transparent with opportunity for justification for not meeting any target. It should have guidance how to improve upon.

These are general measures. A company should add more measures specific to its requirement or based on any psychological study carried out in the industry.

8.6 Motivating Thoughts:

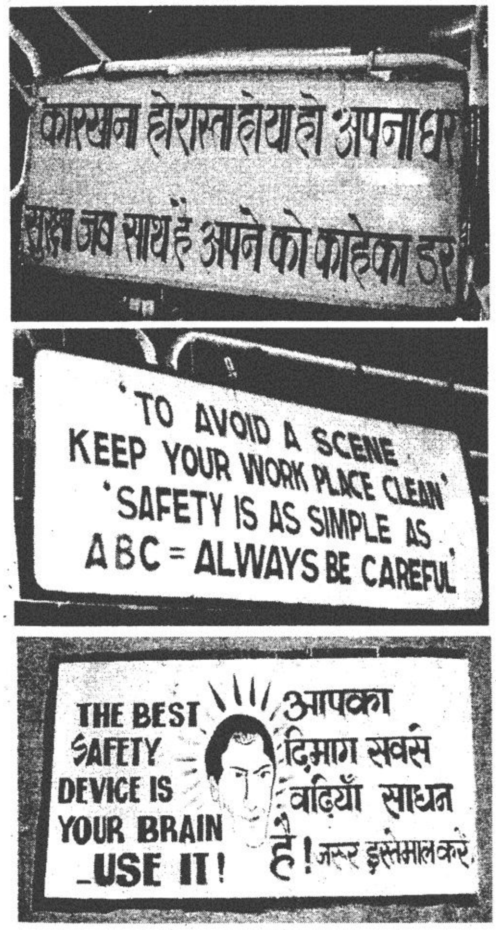


Fig 3.3 Display such Motivating Thoughts

It is said that 'it is not the gun that fires, it i the heart of iron which fires the gun'. After all it is the heart (**with mind**) full of confidence, courage am motivation that drives a man to achieve the goal.

Motivating thoughts or ideas play an important role in this regard. No motivation is possible if human mind is not appealed by inspiring thought. This is true in case of safety motivation also.

We have to motivate workers to work safely and without accident. Therefore it should be impressively brought to their mind that any accident will cause ham to them only and therefore any accident prevention work is in their interest. Some thoughts are given below as an example. Many such thoughts may be developed based on experience and need of time and situation

(1) All are losing by Accidents:

By working in factories, a finger is cut, eye lost, hearing damaged; skin, lungs, stomach deteriorated or cancer contracted, then who is benefited?... Nobody.

Life lost in accident or life span reduced due to pollution, then, who is benefited?... Nobody.

Nobody is ever benefited by any accident. Everybody loses only. The worker suffers pain and aftereffects, loses money in transport, medicine and dispensary expenses. His family members suffer pain and lose time to serve him. Everything is lost of a family whose main person loses life in accident. The deceased cannot be brought back by compensation. Original spare-parts of human body are not available in the market

Fig 3.4 Human body parts are not available in market

The employer loses the benefit of an experienced (trained) person, has to pay compensation in court and incur other expenditure including, medical and transport charges. Time is lost in investigating the accident and repairing the machine if damaged. Production is interrupted and no such skilled worker can be prepared in a short time.

If the deceased is a social worker, society and nation both lose his services. In totality everybody is losing and nobody is gaining by accident. Therefore friends! Do determine from now to stop accident by all means.

(2) Accident causes more Harm to the Worker:

First victim of any accident is worker himself, because he is nearer to the place of accident. Who is exposed to gas or leakage? Worker only. Who hurt by falling, slipping or striking? Worker only. Who hurt by a falling body ? Worker only.

Paying fine or compensation in court may relieve an employer, but can an injured worker be relieved from pain and suffering? No. Can his family get his support if he is died? No.

Thus it is the worker only who loses more by accident. Therefore we have to think of our safety first.

(3) Foolishness:

To provide guard after cutting of fingers, to cause fire and then to extinguish, to discharge gases and then to search mask, to invite emergency and then to rush for control measures... Is it not foolishness?

Therefore, awake, arise and remove all unsafe working conditions and actions first.

(4) Worse than an Accident:

Every year some 2 lakhs people die in accidents in our country. Many more are injured. But the most serious matter is that by inhaling polluted air, we are calling death gradually near and near.

Is it not surprising that this condition of working in polluted air is not called 'accident' because immediate absenteeism of 48 hours is not noticed thereby?

It is always advisable to consider this condition worse than an accident and try to remove it.

(5) Five years deducted from life! :

Whatsoever pay-rise and facilities we may obtain, but, if we continue to inhale polluted air, at the time of retirement, with gratuity, we will certainly get a certificate from the nature- *'Five years are deducted from your life'.*

Do you wish this?

If not, awake and build a wall before the water comes. Do whatever you can do to prevent pollution.

(6) Nothing is costlier than Life:

Everybody loves own life because everything can be experienced till the life is live. Future after life is unknown. All fruits of this world can be enjoyed only until the eyes are open and live. .Therefore nothing is costlier than life. Then why should we lose it by our own mistake? Therefore firmly determine not to commit and mistake to cause an accident to oneself or others.

(7) Safety must be our Way of Life:

Safety motivation must last lifetime. Temporary determination due to any emotional setback or funeral asceticism (smashan-vaimgya) will not last long. Safety attitude must become a habit or part of life. Whenever we see and wherever we see, we must see through the safety-eyes. Our thinking, observing, working or supervising at the workplace, home or anywhere else, must be with safety-eye, safety-outlook, safety attitude and safe behaviour in all respects. Safety cannot be confined with any workplace or any time limit. It has to be with us till we live and enjoy. Therefore it must be our way of life.

(8) Safety needs Active Participation :

Safety begins with our selves. 'Others will practise safety, it is their duty, why should I worry?' is an improper thinking. Safety needs our participation too, because our mistake can contribute to an accident even if everything is all right. And if we do not participate, how can we expect others to participate? Therefore safety needs' our active participation first. Participate yourself in safety and let others encourage or inspire to follow you. This is the only best way of safe behaviour.

(9) Implement, Implement & Implement:

No safety slogan, safety notice or "safety literature, including such books, will save life unless it is practised. Therefore, implement what you know or learn from safety literature.

Don't wait till any accident takes place. Think and prevent the possibility of accident causes. implement all safety measures.

There may be a thin boundary between what is safe and what is unsafe, what is legal and what is not legal. Identify this boundary and implement preventive measures to remain within a safe limit.

(10) Protect the Environment:

Man is born of food,
Food is of plants,
Plants are of earth,

Earth is of water,
Water is of air,
Air is of space and
Space is of God.

One, who ignores this togetherness of life, perishes. Therefore Protect the Air, Water, Earth and Plants - all elements of the God. They will protect you.

(11) Killing of Nature means killing of Self:

gRok p izd`fre~ ,"kke~ vkReuk'ka dfj";fl A
rnk tkxzra Hkks iq:"k% la;E; ro izo`fRre~ AA

By killing, polluting and distorting {he Nature and its Vicinity, are not committing Suicide ? So, O Man, 'Be aware and restrict such wrong practices.

(12) Work of Safety People is Invisible:

Accidents, injuries and losses that take place are visible but those prevented are invisible. By the constant efforts of safety people, hundreds and thousands of possibilities or events of accidents are prevented. This work is neither visible nor measurable. Cost of such prevented accidents and losses is uncountable. Its value is the highest. The work of safety people should be evaluated and assessed in this way.

(13) Safety pledge

"On this day, I solemnly affirm that I will rededicate myself to the cause of safety, health, and protection of environment and will do my best to observe rules, regulations and procedures and develop attitudes and habits conducive for achieving these objectives.

I fully realize that accidents and diseases are a drain on the national economy and may lead to injuries, disablements, deaths, harm to health, damage to- property, social suffering and general degradation of environment.

I will do everything possible for the prevention of accidents and occupational diseases and protection of environment in the interest of self, family, community, organization and the nation at large."

9. BEHAVIOUR BASED SAFETY (BBS)

This is a psychological approach to improve human behaviour for the purpose of reducing accidents.

9.1 Criteria and Strategies:

Psychological concept of 'behavioural safety' or behaviour based safety (BBS) was studied and applied during the years 1968 to 1972 by Aurbrey Daniels, Wanda Myers and others. The research continued and studies during last 15 years showed good results that by observing and changing behaviours of the workers (motivation), accidents can be reduced significantly.

In Hawthorne studies (Part 8.3.1) it was found that 'behavioural approach' was giving good results (accident reduction) than the changes in effects of working conditions like lighting, working hours, rest interval etc. This is die base of BBS concept.

In BBS approach, 'safe behaviours' are targeted, decided and explained to the workers. Then performance of these behaviours is observed. It is also called performance management. Feedback is obtained and reduction in accident rate is measured.

Sometimes a 'design team' is formed by selecting shop-floor workers including representative of supervision and safety department. This team decides following steps:

1. How to observe unsafe practices or acts and to design observation criteria for this.
2. Coaching process to give brief guidelines to improve safety -behaviours to eliminate or reduce those unsafe acts.
3. Plan to use data of observations regarding unsafe acts.
4. Plan to support the process of improvement (motivation for target).
5. Plan training if still required.
6. Plan for maintaining the process.

Thus by such systemic planning, behavioural psychology is used to promote safety at work. BBS approach proceeds as under:

1. Observing unsafe behaviours or acts of the workers in the organisation and collecting then data.
2. Defining a set of model behaviours to reduce the unsafe acts..
3. To give short duration training to workers regarding their unsafe acts, management observations and explaining safe (model) behaviours.
4. Observing new (improved) behaviours and recording their consistency and frequency.
5. Getting feedback and supporting new behaviours.
6. Data collected is used for recognition, problem solving and continuous improvement.

9.2 Management Techniques:

Management control for implementing above BBS concept includes following techniques:

1. Design team of selected workers to record observations, develop support materials and provide training.
2. Identify elements or targets and decide steps to focus on each of them.
3. Organise a full day meeting instead of one or two hours meeting to plan the process after full discussion.
4. Design own steps instead of copying the same from other companies.
5. Do not waste time to complete training of all the workers. Start implementation after training some 20% workers and continue training for others. Thus the time cycle will begin soon to observe the result.
6. Avoid unnecessary training of team members. Those who are already trained need not require training.

E X E R C I S E

1. Comment on the following statements by giving your opinion:

1. 'Human behaviour' is at the top in any accident prevention work.
2. Psychological safety factors are vauge and are of no importance.
3. It is the 'mind' of the man only which is the main driving force of any safety „ activity. Utilize it for safety. .
4. "Every major management problem is in part psychological" - Ordway Tead.
5. Self-discipline is the best remedy for unsafe acts.
6. Proper attitude toward safety is the first requirement.
7. Frustration increases accident rate. .
8. Conflict has no place in safety activity.
9. Individual differences always exist. They are to be reconciled for the purpose of safety.
10. Accident proneness is reality. It cannot be removed.
11. Accident proneness is a vague concept and absurdity. It must be thrown out.
12. 'Psychology lies at the root of sequence of accident causes' - H.W. Heinrich.
13. Every employee is a problem employee.
14. "Motivation is a release of energy toward a desired goal" - Herbert Moore.
15. Psychological factors were found more effective than the working conditions in Hawthorne studies to reduce accidents.
16. Moslow's hierarchy theory of human needs is outdated now-a-days.
17. Motivational factors for safe attitude are difficult to judge. Which should be adopted?
18. Safety Management has many roles to play in motivating workers for safety. Which are these roles?
19. All are losing and nobody is benefited by any accident.
20. Accident causes more harm to the worker himself.
21. Nature's Certificate - "Five years have been deducted from your life" if we continue to work in polluted atmosphere.
22. 'Behaviour based safety' is a good modern concept but how to. implement?

2. Write Short Note or Explain in brief:

1. Need of safety psychology.
2. Industrial psychology.
3. Definition of 'safety psychology'.
4. Employer's psychological problems OR Employee's psychological problems.
5. Accident causative factors.
6. Corrective measures to reduce frustration OR Conflict in industry.
7. Morale- its importance for safety.
8. Difference between fatigue and boredom.
9. The problem employee.
10. Accident proneness.
11. Need of motivation for safety.
12. ERG theory OR Goal setting theory.
13. Methods of job climate improvement.
14. Importance of motivating thoughts and their display.
15. Safety must be our way of life.
16. Concept of Behaviour Based Safety (BBS).

3. Discuss with details:

1. Human factors contributing to accidents.
2. Role of Safety Management in Motivation.
3. Hawthorne studies of behavioural approach or Mashlow's Theory of human needs.
4. Methods of motivation.
5. BBS techniques for accident control.

CHAPTER – 4

Accident Causation and Prevention

THEME

1. CAUSATION OR OCCURRENCE?

The term Accident Causation is preferred against 'Accident Occurrence' because of the safety philosophy that 'Accidents do not occur, they are caused'.

Most of the accidents are caused by our latent or patent, visible or invisible, known or unknown, detectable or undetectable, intentional or unintentional unsafe acts, conditions and sequential events leading to accident. They explain rather the causation and not just the occurrence. Therefore all safety people should find the 'cause' of accident and the appropriate measures for prevention.

The word **'causation'** points out 'our responsibility' to find out cause and preventive measures to remove real reasons causing that accident. The word 'occurrence' points out occurring by chance or fate or something else and indicates nobody's responsibility, which is not the healthy or safe philosophy of safety.

1S:3786 gives seven factors relating to causation of accidents : agency, unsafe mechanical or physical condition, unsafe act,-unsafe personal factor, type of accident, nature of injury and location of injury.

The terminology and philosophy given in Chapter 2 and 3 must be studied before reading any chapter including this one.

2 THE ACCIDENT PROBLEM

The zero accident goal is an ideal goal, and one must try to achieve it by using all safety philosophy and technology. In reality, an industry and accidents are co-related and each industry is facing the accident problem, the nature, number and size may differ.

Nature and Size of the Problem:

It is this accident problem at the root which has generated the need of safety. Deaths, injuries and suffering are its direct results. Compensation, production-loss, time-loss and various costs-losses are indirect results. The injured worker, his family, factory and the nation, all are the sufferers. Accidents not resulting in human injuries, but resulting in property damage or money-loss are also accountable and undesired. Therefore accident is always undesirable. That is why the accident problem has attracted attention worldwide.

Many employers look at it leniently and do not pay proper attention. They feel- that it is cheaper to prolong the hazard than to remove it. Because of the insurance schemes and ESI Act, many employers think that now they should not worry because they have insured their plants and workers against accident and they will be compensated. Such attitude increases the accident-problem and acts against the efforts for safety.

Many workers also tend to take advantage of the ESI Scheme and cause deliberate accidents. This has increased the number of reportable accidents, which can be reduced by the motivation of Workers and then unions. The national money-loss and time-loss by such accidents must be prevented by co-ordinated efforts. Training at all levels helps much in this regard.

The size (severity) of this accident problem can be judged from the (1) Cost of the accidents and (2) Statistics of accidents which are explained in Chapter5 to discuss its various aspects. Yet, some highlights are given below:

In India during 1994 there were total 190435 accidental deaths recorded, out of which the figure in factories was 606 (For other causes see tables in Chapter-5). Total injuries (fatal and non-fatal accidents) during 1982 and 1983 were 296027 and 213160 respectively. This figure in 1990 and 1991 was 128117 and 60599 respectively. This indicates decrease in accidents despite increasing industrialisation and employment. This is owing to non-reporting of accidents from many states. See Part-2 of Chapter-5 for such inadequacy of data. Yearly ©6000 fatal and 6 lakhs reportable injuries are estimated in factories of our country.

The accident-tall in factories of the Gujarat State is also given in Tables of Chapter-5.

Similarly figures for accident compensation and expenditure can be obtained from all insurance companies, ESIC authorities, hospitals, dispensaries and other sources to understand the accident problem from all sides. Some 50 crores rupees are estimated as national cost of injuries per year.

The accidents are classified industry-wise and causation-wise. Such classification and breakup are explained in Part 3.5 and 3.6 of Chapter-19. See also Table 5.22 of Chapter-5.

Besides human injuries, there are property damage .(no injury) accidents, which are 10 to 20 times higher than the first-aid accidents.

Non-reporting and under reporting of accidents (including occupational diseases), make this problem more severe. Reported figures are quite inadequate.

The accident problem emphasises the need for safety and accident prevention techniques, which are discussed below.

3. NEED FOR SAFETY

Much is said and can be said for the need of safety. Everybody recognises its need. A few factors are given below:

1. Industries are increasing to fulfil basic human needs food, clothing, home, employment or earning and requirements of goods, services and facilities. This brings industrial hazards of various types viz. mechanical, electrical, noise, vibration, chemical (fire, explosion, radiation, gas, dust, fumes, poisoning etc.) and many visible or invisible health hazards. It is the basic need to protect the human life and environment from all such hazards. Only safety can do it.

2. Direct and indirect costs of accidents are tremendously increasing and causing the great national loss. This can be prevented by safety (see Part 4, Chapter - 5).

3. Workers are our national wealth. We cannot afford to lose them. Fatal accidents must be minimised to prevent this fatal loss.

4. Deaths and injuries extend suffering to the families and society also. This must be prevented or curtailed by safety.

5. Social loss in the form of pain, loss of earning capacity, loss of life or limb, ill-effects to health, diseases, increase of handicapped persons, increase of court cases and emotional losses due to accidents must be reduced by safe conditions, safe practices-and training for them.

6. Productivity is linked with safely. Increasing and maintaining safety gives good productivity.

7. Humanitarian, legal, social and economic reasons for accident prevention are also true for the need of safety. They are explained below.

Based on above requirement, it can be said that 'AS place of industry in society is inevitable, place of safety in industry is also inevitable. As industry is useful to society, safety is useful to industry.

4. REASONS FOR ACCIDENT PREVENTION

Five main reasons for accident prevention are stated below and shown in Fig. 4.1.

Fig. 4.1 : Reasons for Accident Prevention

4.1 Humanitarian or Basic Need for Safety:

The vedic philosophy that a man should protect man is the fundamental or basic reason for accident prevention. Employers should protect their workers by providing good working conditions, safety equipment and training. It is their humanitarian or moral or basic duly under the common law. Similarly the employees should also protect themselves and their fellow employees and surrounding, by their safety duty, precautions and safe practices. Protection of self and others is the primary duty of every person from humanitarian point of view. Our Hindu culture thinks of protection of birds, animals and all living creature far beyond the human protection.

To minimise deaths and injuries, pain and social suffering is the basic need for accident prevention.

For any industrial activity five 'M's are required
Manpower,
Money,
Material (includes machinery),
Management, and
Market.

Out of these, only manpower is a live element and others are dead, functional and operated by men. All other factors are for men only. Management and market cannot function without men. Money and material cannot flow without men. Machinery cannot be designed, operated and maintained without men. Thus **'man'** is predominant and most important factor in all industrial activities. Prevention of accident to 'man' is. 'therefore most essential. It is humanitarian.

4.2 Economic or Costs of Accidents:

There are three agencies that suffer economic losses due to accidents:

1 Worker and his family.
2 Management.
3 Society and nation.

Worker & his family suffer economic losses clue to loss of life or limb, loss of earning capacity and extra expenses viz. medical, nutrition, transport etc. Emotional and mental suffering is extra loss.

Management sustains money loss due to direct (insured) and indirect (uninsured) costs of accidents (For details see Part 4 of Chapter-5). The above costs added together give the total cost to the organisation. The top management should consider cost benefit analysis and adopt cost effective safety measures to reduce such costs, pain and suffering.

Prevention or reduction in accident cost is direct benefit to the company. Investment for safety should be considered always necessary.

4.3 Social:

Society is benefited by help from the men and goods, services and production from the men.

Injury or death of a worker is not an individual loss but directly and indirectly it is a loss to the society also because a man does not live in isolation. He is connected with society and has many relations in many directions. Therefore loss of a person is loss to the society by way of his usefulness to the society.

4.4 Legal:

Legal reasons for accident prevention are due to laws framed by the Government

It is the statutory duty of occupiers under the Factories Act 1948 and other Acts to provide safe conditions for the prevention of accidents and protection of workers. Breach of law may .result in prosecution, fine, punishment and adverse publicity. Heavy penalty and compulsory imprisonment are provided for breach of certain safety provisions resulting in death or serious bodily injury. Enhanced penalty is prescribed for repeated offence. The court can pass an order for compliance also. The inspector has power to issue an order to require safety measures before a specified date or to prohibit to run the factory till the compliance is carried out. Thus legal reason for accident prevention is strictly set out for the employers, and is supported by the Courts' judgements.

The statutory duty is imposed upon employees also to observe safety rules, maintain safety guards and conditions, and to use safety equipment so as not to injure self and others.

In democracy, everybody suppose to know and follow the law. of the land.

4.5 Productivity:

'Safety increases productivity,' needs to be understood.

Peter Drucker defines productivity as "the balance between all factors of production that will give the greatest output for the smallest effort (input)". It is maximum when highest output is obtained with minimum expenses of resources and when resources are not used in the most economical manner.

Productivity requires elimination of loss in all forms viz. losses of men, materials, machine, manufacturing process, products, money, time etc. It covers many factors from design to disposal level. Safety maintenance for accident prevention reduces such losses, cuts accident costs and helps directly in increasing productivity. The employers must recognise this fact and must invest sufficient money for accident prevention and reduction programmes, which will save money, time and injury losses due to accidents and increase their productivity and profit.

Thus a safe way is the best way and safety is a key to productivity. It is also said that safety and productivity go hand in hand or they are two sides of a coin.

Thus safety and productivity are equally important and help each other. However in practice, many times production people consider safety as an obstruction or brake to their work and require workers to go ahead by any means to meet production target. Such attitude may result in accident which will retard productivity.

5. FACTORS IMPEDING SAFETY

The factors impeding i.e. retarding or injuring safety are those factors, which go against the efforts for safety. It is necessary to identify such negative factors (as they cause hazards) and to remove them for the purpose of safety.

A list of such factors may be very long and may vary 'from factory to factory. Some common factors are classified and given below:

5.1 At the Management Level:

1. Passive interest in safety by the management. No safety policy.
2. Compromising with safety for production.
3. Poor maintenance of machines and equipment.
4. Poor working conditions or not providing proper lighting and ventilation, safety guards, devices and equipment.
5. Ageing or corrosion of the machines, plant and buildings.
6. Improper location and layout of plant, building, machinery and equipment.
7. Improper design or selection of tools, machines, materials, vessels, equipment and products.
8. Improper methods, procedures or use. of raw materials, machines, equipment etc. in storage and manufacturing process.
9. Lack of inspection, supervision and training for safely.
10. Absence of safety organisation for proper and continuous attention on safety.
11. Lack of awareness and insistence for safety.
12. Improper selection or placement of men, machines, methods, tools, equipment etc.
13. Lack of motivation and participation for safety.
14. Poor infrastructure of the organisation.
15. Poor financial condition of the organisation or not providing sufficient safety budget.
16. No written rules for job description, procedure and safe production.
17. Lack of safety aspects in accident prevention.
18. Frequent changes in shifts, working hours and calling workers for overtime work or on holiday etc.

5.2 At the Workers Level:

1. Passive interest in safety by workers. No or less participation in safety programmes including safety committee.
2. Insufficient knowledge, qualification and training for the job.
3. Reluctant to use PPE and other safety equipment.
4. Not maintaining the machine guards, safety devices, equipment etc.
5. Misuse of guards, safety devices, protective equipment etc.
6. Indiscipline, laziness, disobedience for safety rules for whatsoever reasons.
7. Non co-operation to the management to carry out regular as well as emergency safety duty for safe close down or safe running of the plant and processes to avoid accidents.
8. Guided by personal (psychological) factors causing unsafe actions.
9. Poor socio-economic status, financial hardship, family problems, worries, tensions etc.
10. Improper attention or judgement on the matters of safety.

5.3 At the Government Level:

1. Not enacting or amending requisite safety laws and poor or non-implementation of the enacted safety laws.
2. Poor or no incentives, awards, rewards, programmes, subsidy, rebates, text benefits and encouragement to employers and employees for their safety efforts.

6. BASIC TERMS IN ACCIDENT PREVENTION

See Part 3 "Safety Terminology" of Chapter-2 for the definitions of terms. The words - accident, accident prevention, damage, danger, hazard, injury, loss control and prevention, risk, safety, unsafe act, unsafe conditions etc., are defied therein.

The basic terms directly connected with **accident causation** are discussed below:

6.1 Incident:

See part 3.43, Chapter -2 for definition.

For accident phenomenon, it indicates event that results in accident.

6.2 Accident:

See Part 3.1 of Chapter 2 for definitions and philosophy.

It is an undesired-or unintentional event that results in physical harm to a person or damage to property or environment. It is usually the result of a contact with a source of energy (mechanical, electrical, thermal, chemical, etc) above the threshold limit of the body or structure.

The term *physical harm* in above definition includes injury, death, disease and adverse mental, neurological or systemic effects resulting from an exposure or circumstances encountered in the course of employment.

Heinrich's definition of an accident is "An unplanned and uncontrolled event in which the action or reaction of an object, substance, person, or radiation results in personal injury or the probability thereof". Like a mathematical theorem he concludes:

1. A personal injury occurs only as the result of an accident.
2. An accident occurs only as the result of a personal or mechanical hazard.
3. Personal and mechanical hazards exist only because of the faults of persons.
4. Faults of persons are inherited or acquired by environment.

This theorem points out personal fault (unsafe act) as the root of any accident A person designs, manufacturers, operates and maintains a machine, equipment, plant etc. His fault (error or mistake) lying anywhere from design stage to maintenance stage may cause an accident which results in injury.

An 'accident' is also defined as "An unplanned and unexpected event which causes or is likely to cause an injury".

An 'accident' is the result of carelessness, casualness or any fault known or unknown. This points out that carelessness and casualness (taking thing lightly) or any hidden fault can cause an accident.

Sachman defined in 1961, accident as an event which is unexpected, unavoidable and unintended. However other researchers of accident causation analysis say that most of the accidents are avoidable or preventable. This concept emphasises the need and importance of control technology to minimise the accidents.

'Accident' as defined by 'Accident Facts, NSC, USA' in their 1997 edition, is that occurrence in a sequence of events which produces unintended injury, death or property damage. Accident refers to the event, not the result of the event, while unintentional injury refers to the result of an accident and is the preferred term for accidental injury.

It is also defined as "An unplanned or unintended occurrence that interrupts or interferes with a work activity". This definition is based on the fact that many accidents, the great majority, yield no injury and receive passing attention only.

Thus there may or may not be any injury to person or property, the only symptom of an accident is 'interruption or interference with a work activity or energy transfer'. This is the broad definition, giving rise to the concepts of 'Damage accident', 'Lost-time accident', 'Total loss control' and 'Total loss prevention'.

Nowadays we see 'planned or intended accident' also, but, then they may fall under the Indian Penal Code as offences against person or property.

Primarily, in industry, an accident is considered as (in unplanned or unexpected event resulting in injury to a person or property or both. Damage accidents (without human injury) are secondary. Statutorily some damage accidents (dangerous occurrences) are reportable under the Factories Act, 1948.

The word 'accident' as defined by Indian Standard: 3786 - 1983 means an unintended occurrence arising out of and in the course of employment of a person resulting in injury.

For the purposes of the Workmen's Compensation Act 1923, 'a personal injury caused to a workman by accident arising out of and in course of his employment is said eligible for compensation depending upon the types of injuries listed in Schedule-I and the occupational diseases in Schedule- III of the Act.

The word accident is not defined in the Factories Act. Its reporting is defined as follows (Section 88).

Notice of certain accident: where in any factory an accident occurs which causes death, or which causes any bodily injury by reason of which the person injured is prevented from working, for a period of forty-eight hours or more immediately following the accident/or which is of such nature as may be prescribed in this behalf, the manager of the factory shall send notice thereof to such authorities/and in such form and within such time, as may be prescribed.

Report of accident to a person or animal is also required under the Electricity Act and Rules.

Thus the pure or theoretical definition of 'Accident' includes 'event' but not necessarily its result as injury or damage. In this context, it is as good as 'near-miss' and accident may or may not have injury. The legal or practical definition of 'accident' includes both 'event' and 'injury' otherwise it is not an accident.

'Accident' prescribed under Rule 103 of the Gujarat Factories Rules, considers 'injury'. It also prescribes 'dangerous occurrences' which may or may not include personal injury.

An accident sequence and consequence are explained in Part 7.1 following.

6.3 Injury:

To injure means 'to hurt' and an injury means 'a harm'. In legal terms injury may be to a person or property or both and compensation (damages) can be awarded to the injured person for the loss he has suffered and may continue to suffer. Punitive damages can be awarded for grave injury.

An injury could be **psychological** also and not necessarily a physical condition resulting from a mechanical, electrical, chemical or radiological accident. A heart attack resulted from unusual mental stress from the work is injury for which compensation is payable. But natural death or heart attack during normal activities may not be considered as an injury from accident.

Injuries are not considered resulting from an accident where wilful death, self-inflicted intentional injury, intoxication and undue alteration by the person injured are involved.

There are two types of injuries. Minor injury generally means that having no permanent effect and leading to less than three days off work. Major injury generally means that leading to more than three days off work. The major injury may be fatal (death) or serious. A fatal injury is a great loss to the worker, his family society and the employer.

An **injury** is an external damage to the human body, disturbance or dysfunction resulted from an accident.

By **cause**, injuries may be mechanical (bruise, cuts, tissue ruptures, breakage etc.), thermal (shock, burn, frost-bite), chemical (bum, acute intoxication and poisoning), radiated (tissue regeneration, changes in the haematopoietic system), or combined (the effect of more than one causative factor with various consequences). The result of accidents (which may cause serious, minor or no injury) may be temporary or permanent disablement or a fatality (injury).

The term **"accidental injury"** denotes an injury to a workman due to an accident. It does not include an injury to a worker's health unless it results directly from an accident, as for example, a poisoning due to toxic chemical.

"Serious bodily injury" as defined in section 92 of the Factories Act means "An injury which involves, or in all probability will involve, the permanent loss of the use of, or permanent injury to, any limb or the permanent loss of, or injury to, sight or hearing, or the fracture of any bone, but shall not include, the fracture of bone or joint (not being fracture of more than one bone or joint) of any phalanxes of the hand or foot".

An injury is merely the result of an accident: An accident is controllable, but, when it occurs, it is difficult to control the resulting injury. The severity of accident depends upon the material causing injury, energy released, body part being injured and the physical or mental condition of the person being injured. As accident precedes injury, attention should be paid to prevent the accident.

H.W. Heinrich estimates that in a unit group of 330 accidents of the same kind and involving the same person, considering average of averages, 300 result in no injuries, 29 in minor injuries and I in a major lost-time injury. It indicates **an ample opportunity to prevent any injury** by efforts during 300 no-injury or warning accidents. This foundation of a major injury is shown in Fig. 4.2.

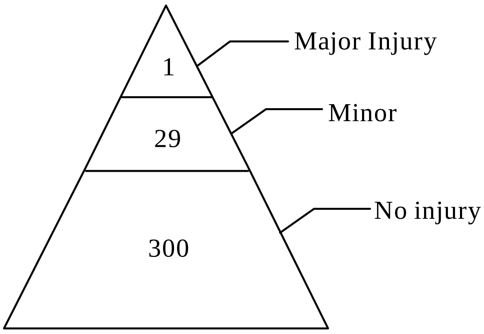

Fig. 4.2 : Foundation of a major injury

See Part 7.1 for further discussion on this ratio theory.

6.4 Dangerous Occurrences:

U/s 88A of the Factories Act and u/r 103 of the Gujarat Factories Rules, the following occurrences are prescribed as dangerous and they are reportable in Form No. 21 (for bodily injury or death) & 21A (for no bodily injury, property damage may or may not be resulted):

1. Bursting of a steam plant under pressure.
2. Collapse or failure of lifting appliances or overturning of a crane.
3. Fire, explosion, escape of molten metal, hot liquor, gas etc.
4. Explosion of a pressure vessel.
5. Collapse or subsidence of a structure.

6.5 Dangerous Operations:

The term 'dangerous operation' is used in section 87 of the Factories Act meaning 'Any manufacturing process or operation carried on in a factory exposing any person employed in it to a serious risk of bodily injury, poisoning or disease' and the State Government is advised to make rules regarding dangerous operations.

Rule 102 of the Gujarat Factories Rules lists 27 Schedules of such dangerous operations.

The details of all above schedules suggest preventive measures for serious risk of bodily injury, poisoning or occupational diseases. They must be thoroughly studied and implemented.

6.6 Hazardous Processes & Industries :

Section 2(cb) of the Factories Act, 1948 .defines 'hazardous process' as follows:

"Hazardous process" means any process or activity in relation to an industry specified in the First Schedule where, unless special care is taken, raw materials used therein or the intermediate or finished products, by-products, waste or effluents thereof would (1) cause material impairment to the health of the persons engaged in or connected therewith, or (2) result in the pollution of the general environment.

The First Schedule of the Factories Act lists 29 hazardous industries.

6.7 Occupational (Notifiable) Diseases:

The Third Schedule under the Factories Act gives a list of 29 notifiable occupational diseases and poisoning.

Schedule III of the Workmen's Compensation Act 1923 also gives a list of 34 occupational diseases in its part A, B &: C. A similar list is also given by the ESI Act

Only statutory occupational diseases are listed above, but, there are many non-statutory diseases also which need accident or disease prevention. For details see Part 4 of Chapteir-24.. .

Thus legal terms accident, dangerous occurrence, dangerous operation, hazardous process and notifiable disease require *personal bodily injury, impairmental to health or environment pollution i.e. without these, they are incomplete.*

Thus those accidents (including diseases and poisoning) are given more attention, which pose **injury** to a person, property or environment.

7. THEORIES OF ACCIDENT CAUSATION

Various theories are developed to explain the phenomena of accident causation as under. They are useful to understand the mathods of prevention also.

7.1 Heinrich's Theory:

H.W. Heinrich, a pioneer in safety philosophy, first published his work. Industrial Accident Prevention, in 1931. Many of his principles and basic philosophy of accident causation and prevention are confirmed by time and application, but, some are also questioned and criticised. His philosophy is based on his 10 axioms (self evident-truths) as follows.

Ten Axioms of Industrial Safety:

1. The occurrence of an injury invariably results from a completed sequence of factors - the last one of these being the accident itself. The accident in turn is invariably caused or permitted directly by the unsafe act of a person and/or a mechanical or physical hazard.

2. The unsafe acts of persons are responsible for a majority of accidents.

3. The person who suffers a disabling injury caused by an unsafe act, in the average case has had over 300 narrow escapes from serious injury as a result of committing the very same unsafe act (see fig. 4.2). Likewise, persons are exposed to mechanical hazards hundreds of times before they suffer injury.

4. The severity of an injury is largely fortuitous the occurrence of the accident that results in injury is largely preventable.

5. The four basic motives or reasons for the occurrence of unsafe acts provide a guide to the selection of appropriate corrective measures. These are: Improper attitude. Lack of knowledge or skill, Physical unsuitability and Improper mechanical or physical environment.

6. Four basic methods are available for preventing accidents. These are Engineering revision, Persuasion and appeal. Personnel adjustment and Discipline.

7. Methods of most value in accident prevention are analogous with the methods required for the control of the 'quality, cost and quantity of production.

8. Management has the best opportunity and ability to initiate the work of prevention, therefore it should assume the responsibility.

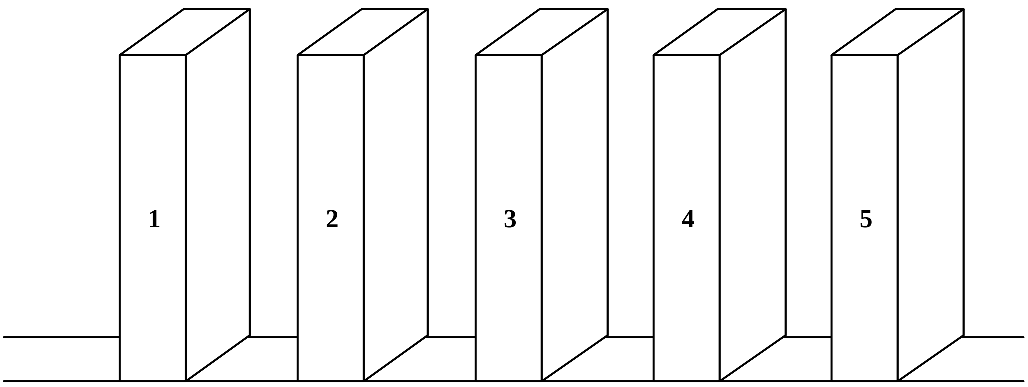
9. The supervisor or foreman is the key man in individual accident prevention. His application of the art of supervision for the control of work performance is the factor of greatest influence in successful accident prevention. It can be expressed and taught as a simple four step formula - Identify the problem, find and verify the reason for the existence of the problem, select the appropriate remedy and apply the remedy. The humanitarian incentive for preventing accidental injury is supplemented by two powerful economic factors: (1) The safe establishment is efficiently productive and the unsafe establishment is inefficient (2) The direct employer's cost of industrial injuries for compensation claims and for medical treatment is about one-fifth of the total (direct plus indirect) cost which the employer must pay.

These axioms were the first set of principles or guidelines ever set before in industrial safety and it has guided all safety activity till today. During the passage of 75 years, some of his axioms are questioned and disbelieved as truths, but, most of them are still true and deal with the important areas of safety, viz. accident causation and prevention, reasons of unsafe acts and conditions, management control functions, responsibility of organisation, costs of accident, safety and productivity etc.

Accident Sequence: *The five factors .in accident occurrence series in chronological order are:*

1. Ancestry and social environment.
2. Fault of person.
3. Unsafe act and/or mechanical or physical hazard.
4. Accident and
5. Injury

One factor is dependent on another and one follows because of another, thus constituting a sequence that may be compared with a row of dominoes placed on end and in such alignment in relation to one another that the fall of the first domino precipitates the fall of the entire row. An accident is merely one factor in the sequence. If this series is interrupted by the elimination or withdrawal of even one of the five factors that comprise it, the injury can possibly be prevented. See Fig. 4.3.



1. Ancestry & Social environment
2. Fault of a Person (undesirable traits)
3. Unsafe act or/and condition
4. Accident
5. Injury

Fig. 4.3 : Five Factors in Accident Sequence

In above dominos, social environment includes family and surrounding atmosphere in which a person is born and brought up. This is the origin or root cause of behavioural development as per H. W. Heinrich.

Undesirable traits include unsafe behaviour, negligence, lack of knowledge, violent temper, nervousness, recklessness etc.

Unsafe act or conditions are the results of undesirable traits.

Accident is caused because of unsafe act or condition 6r both.

Injury is the result of accident.

This suggests the steps of management controls as under:

Management Through Supervision

Controls

Human Failure
Knowledge – Attitude – Fitness – Ability

Which causes or permits

Unsafe Acts of Persons (88%)	Unsafe Mechanical, Chemical, Physical Conditions (10%)
1. Operating without authority or clearance, failure to secure or warn.	1. Unguarded, absence of required guards.
2. Operating or working at unsafe speed.	2. Inadequate support or guards, guards of improper height, strength, mesh etc.
3. Making Safety devices inoperative. 3	3. Defective, rough, sharp, slippery, decayed, cracked surfaces etc.
4. Using unsafe or defective equipment, or equipment unsafely or improperly.	4. Unsafe design of machines, tools, plant, equipment or supplies.
5. Unsafe loading, placing, mixing , combining, etc.	5. Unsafely arranged, poor housekeeping, congestion, blocked exists, etc.
6. Taking unsafe position or posture.	6. Inadequately lighted, sources of glare etc.
7. Working on moving or dangerous equipment.	7. Inadequately ventilated, impure air source etc.
8. Distracting, teasing, abusing, startling horseplay etc.	8. Unsafely clothed, no goggles, gloves or masks, wearing high heels etc.
9. Failure to use safe affair or personal protective equipment or devices.	9. Unsafe processes, mechanical, chemical, electrical, nuclear hazards etc.
10. Failure to warn co-workers or to secure equipment.	10. Inadequate warning systems.
11. Improper lifting.	11. Fire & Explosion hazards.

12. Servicing equipment in motion. 13. Use of drugs or alcohol.	12. High noise or vibration. 13. Hazardous dusts, gases, fumes vapours etc.

Which causes or permits

Accidents
98% Preventable type
2% Unpreventable
50% Practicably preventable

From other similar studies, Heinrich concludes that, "all agree in general that man failure is predominantly the proximate and direct cause of industrial, accident".

The Economic Times, Mumbai, of 21-9-97 gave following figures of Railway accidents:

Year	92-93	93-94	94-95	95-96	96-97
Failure of Railway Staff	363	358	351	237	249
Failure of other persons	60	72	76	71	59
Other causes	101	90	74	88	73
TOTAL	524	520	501	396	381

This supports Heinrich's conclusion that human failure is the predominant cause of accidents. However, this is not necessarily applicable to all or majority of the industrial accidents as per other theories.

To find out rate of human failure, software "Technique of Human Error Rate Prediction (THERP)" is available. See Part 1.15 of Chapter -19.

Criticism of Heinrich's Theory and His Reply:

H.W. Heinrich's ratio theory (fact finding from a study of 75000 accident cases) that 88% accidents are due to unsafe acts, 10% due to unsafe conditions and 2% unpreventable is criticised as follows:

Heinrich made his analysis from reports submitted to insurers by the managers of the companies at which the accidents happened. No manager would want to indicate to the insurer or to the safety authority or agency that the company had been at fault and that hazards existed in the workplace under his control. Such a statement may sound harsh but is borne by known practices, which also distort statistical data.

This ratio idea is fallacious because it rests on a false assumption that accidents are result of either unsafe acts or unsafe conditions. Actually there are multiple (combined) factors as supported by the results stated below.

A study conducted by the National Safety Council (USA) yielded the following conclusions:

18% injuries due to mechanical causes.
19% injuries due to personal causes.
63% due to a combination of both causes.

A study by the Department of Labour and Industry of the State of Pennsylvania yielded the following:

3% "due to mechanical causes.
2% due to unsafe acts.
95% due to a combination of both causes.

The ratio idea had done much harm and many employers still say, 'Why should first of all we spend a lot of money on only 10% mechanical causes? We will start after 88% personal causes are removed by the employees'.. Such concept is damaging. There are two essentials in every case of injury - there must be some degree, of hazard and there must also b~ faulty behaviour by someone. If the factor of hazard is properly detected and eliminated, there could be no injury. Similarly, if behaviour could be made and kept perfect, the result would be the same. Both these are the duties of every management It must try collectively to combat the combined causes of accident and should not separate the unsafe acts as employee's responsibility only. Law always stresses for employer's responsibility first. Why? Because the primary duty, money and ultimate control lie with the management to detect and remove unsafe conditions actions and to give necessary training to the workers. This is the only safe and healthy approach.

Heinrich is aware about the public debate and criticism of his 88-10-2% ratio in accident causation stated above and its wide spread that may influence people to ignore the machine guarding and to take the assumedly easier path of issuing instructions. In reply, he states his belief that the accident-prevention fraternity, like almost all professional groups, want all the pertinent facts and he has more faith in-their good judgement than to fear that they will ignore the very first common-sense step of safeguarding mechanical environment. *The machine is dangerous as man makes it so. It's man's use of the machine - more correctly, his abuse of it - that creates danger.*

He points out that judgement must be used in selecting the major cause when a mechanical hazard and an unsafe act both contribute to accident occurrence. Personal judgement may lead to error, but it is defensible and in the majority of cases results in fair conclusions.

The 300-29-1 Ratio (Foundation of lost-time accident - Explaining the foundation of a major injury, Heinrich estimates that in a unit group of 330 accidents of the same kind and involving the same person, 300 result in no injuries, 29 in minor injuries and I in a major lost-time injury. See Fig. 4.2. He explains this 300-29-1 ratio as an aid in accident prevention, because, it vividly emphasises preventive opportunity, when an employee, either because of his repeated unsafe action or repeated exposure to an unsafe mechanical condition, suffers 300 no-injury accidents (actual events such as slips and falls but fortunately not causing injury) surely there can be no lack of opportunity in preventive effort.

Replying misunderstanding and misquotation of this ratio, he states that this ratio is an average. Sometimes a major or serious injury occurs the very first time a person acts unsafely or is exposed to mechanical hazard – in other cases he is so endangered hundreds or thousands of times and may slip or fall many times before injury is sustained. In industry, where, employees are under supervision, these unsafe practices, conditions and the resulting narrow escapes from actual injury (events-accidents) are tangible and visible. They can and should be controlled long before one of the 300 no-injury accidents ultimately causes an injury.

In above ratio - cases, a major injury is any case that is reported to insurance office or to the State Compensation Commissioner. A minor injury is a scratch, bruise, or laceration such as is commonly termed a first-aid case. A no-injury accident is an unplanned event involving the movement of a person or an object, ray, or substance (slip, fall, flying object, inhalation etc.), having the probability of causing personal injury or property damage but not resulted in injury (near miss).

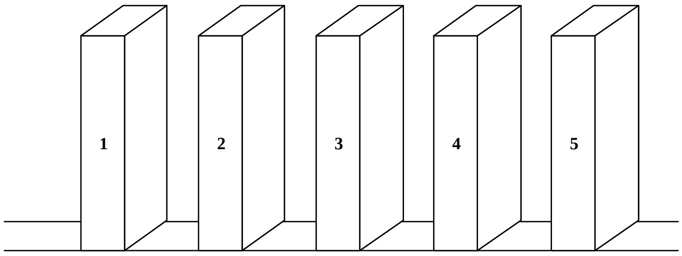
Safety and Productivity - Citing the study made by the Committee on Safety and Production of the American Engineering Council, Heinrich has narrated the detail findings some of which are given below :

1. Industrial accidents can be controlled under modern conditions of highly efficient productivity.
2. Efforts to improve safety performance do not interfere with production.
3. Maximum productivity is ordinarily secured only when the accident performance tends toward the irreducible minimum.
4. The cost of accidents is a loss in industrial operation, which should not be neglected.

7.2 Frank Bird's Domino Theory

Heinrich's theory of domino sequence is updated by Frank Bird Jr. to explain the circumstances that lead to losses (injury) in the chronological order of five dominoes.

These are shown in Fig. 4.4 and explained below :



1. Lack of control - Management.
2. Basic causes - Origins.
3. Immediate causes - Symptoms.
4. Accident - Contact, and
5. Injury/damage - Loss.

Fig. 4.4 : Frank Bird's Domino Sequence

Lack of control is the first domino and refers the fourth function of the management (planning, organising, directing, controlling and coordinating). It involves accident investigation, facility inspection, job analysis, personal communication, selection and training, 'standards' in each work activity identified, measuring performance by standards and correcting performance by improving the existing programmes. This first domino may fall due to inadequate standards, programmes and follow up.

Basic Causes (origins) are (1) Personal factors lack of knowledge or skill, improper motivation and physical or mental problems and (2) Job factors inadequate work standards, design, maintenance, purchasing standards, abnormal usage etc. These basic causes are origin of substandard acts and conditions and failure to identify them permits the second domino to fall, which initiates the possibility of further chain reaction.

Immediate causes are only symptoms of the underlying problem. They are substandard' practices or conditions (known I as unsafe acts and unsafe conditions) that could cause the fourth domino to fall. These causes should be identified, classified and removed by appropriate measures.

Accident or incident is the result of unsafe acts or/and unsafe conditions. This point is the contact stage. Some counter measures employed are deflection, dilution, reinforcement, surface modification, segregation, barricading, protection, absorption, shielding etc.

Injury includes traumatic injury, diseases and adverse mental neurological or systemic effects resulting from workplace exposures. 'Damage' includes all types of property damage including fire. The severity of losses involving physical harm and property damage can be minimised by prompt reparative action, salvage in the case of property damage and fire control devices and trained personnel.

Frank E Bird, in 1969, analysed 1753498 accidents reported by 297 companies of America. His conclusion is shown in Fie. 4.5.

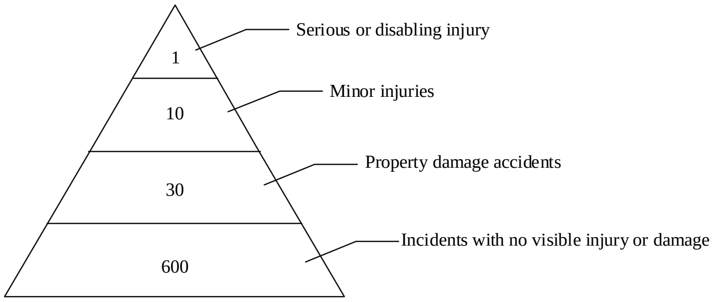


Fig. 4.5 : The Bird's accident ratio study

Inference of this 1-10-30-600 ratio is that 630 no injury accidents, with 10 minor and I major (serious) injury accidents, provide a much larger basis for many opportunities to prevent any injury accident. Out of total 641 events, only 10 may result in minor injuries and only 1 in major injury. But this can happen at any time not necessarily at the end.

7.3 Hepburn's Theory

H.A. Hepburn amplified the above Heinrich's theory and arrived at the principle that an injury accident is the result of the convergence at the same point of time of 4 factors (1) Unsafe actionable (2) Unsafe conditional (3) Proximate casual and (4) Personal.

Unsafe Actionable
↓
Personal → Accident ← Unsafe conditional
↑
Proximate casual

Here unsafe actionable and conditional factors are as usual Personal factor means person injured or likely to be injured by an accident and die person causing the accident. The proximate factor is that immediate causative factor such as failure of a brake, sudden exposure to gas etc., which by its reaction causes a sudden closing together or convenience of all the four factors to cause an injury accident He emphasises that lie four factors are complementary to one another m causation of any injury-accident such that, if any one or more can be withdrawn by any means during or just before convergence, an injury accident can be prevented. The event of an accident will not be prevented by efforts to control any one of the factors to the exclusion of the others. Remedial measures must be adopted for each of the factors. Like Heinrich he also suggested planning and organizing to prevent unsafe actions and remove unsafe mechanical or physical conditions.

7.1 V.L. Grose's Multiple Causation Theory:

As per this theory many contributing factors combine together UK random fashion, causing accidents. Such factors should be identified. As shown in figure 4.6, mostly man, machine and media interact with each other to generate causes for accident and management has to identify them and provide necessary safety measures.

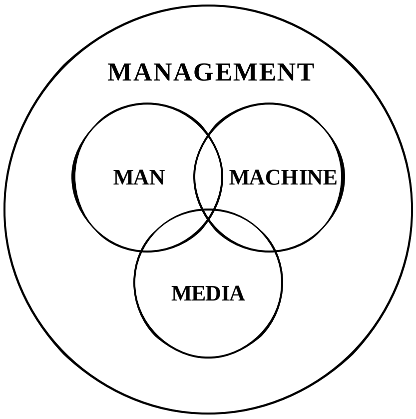

Fig. 4.6 : Multiple intersecting cause

In this theory

1. Man includes- workers, public etc.
2. Machine includes- equipment, vehicle etc.
3. Media includes- environment, weather, roadways etc.
4. Management means within which above three parameters operate i.e. to be controlled by the management.

Characteristics of –

1. Man includes- age, sex, height, skill level, training, motivation etc.
2. Machine includes- size, weight, speed, shape, material of constriction, energy etc.
3. Media includes- pressure, temperature, content, contaminants, obstruction on road etc.
4. Management includes- structure, style, policy, procedure, communication etc.

Simple example of this theory is a man slipping due to walking on a banana skin lying on .the road. Here main contributing factors are as under:

Man - A man walking on the road. Machine or object or vehicle - Slipprery banana skin.

Media - Hard road.

All above causes are interacting with each other to lead to the accident. Absence of any one cause can avoid the accident This indicates that slippery banana skin should be removed from the road or man should be more attentive for not walking on it or the road should not be so hard to cause slipping.

Let us take another example of a worker falling from a ladder. As per the domino theory an investigation is as under :

The unsafe Act	Climbing the defective ladder
The unsafe condition	The defective ladder
The remedial measure	Remove or repair the defective ladder and train that worker

As per the multiple causation theory some of the contributing factors surrounding this accident can be found out by asking :

1. Why was the defect in ladder not found in normal (past) inspections?
2. Why did the supervisor allow its use? Why did he not get it repaired urgently?
3. Didn't the injured worker know he shouldn't use it?
4. Was he properly trained or not?
5. Was he reminded or cautioned?
6. Did and do the supervisor examine the job first?

The answers to these and similar questions would suggest the following measures:

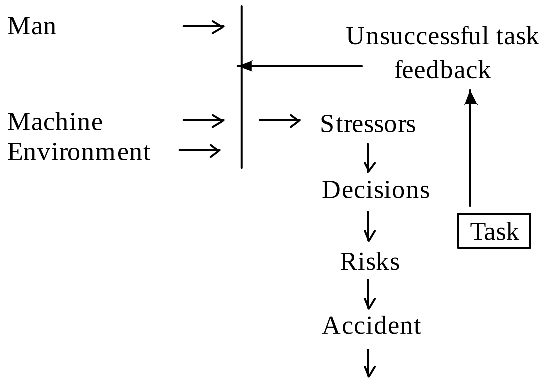
1. An improved inspection procedure.
2. Repairing the ladder (machine-tool, job etc.) immediately i.e. not waiting for an accident.
3. Improved training and supervision.
4. Better fixation of responsibilities.
5. Pre job planning and checking by supervisors.

Thus application of the multiple causation theory leads us to deep causation analysis and improved management systems are suggested to eradicate the problem from its origin. The range and depths of the multiple causation factors provide much details of long-run safety measures.

7.5 Systems Model Theory :

Similar toV.L. Grose's multiple causation theory, Bob Firenze developed a system model theory as under:

Here interaction between man, machine and environment (basic pre-elements for any accident) leads to an accident if the information available to the important element of the system is inadequate. If the risk is high and the decisions based on information are illogical and unsound, an accident occurs resulting into incompletion of the task. Bob Firenze's system model is shown below:

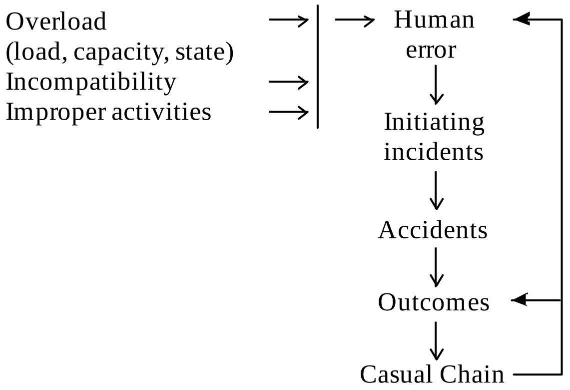


This necessitates the introduction of feedback system (as shown in diagram) to find out the faults/ causes in man, machinery and environment. The information that the man possesses can be strengthened through training. The stressors can be precedent in the following form -

1.	Psychological stressors	Anxiety, aggressiveness, fatigue.
2.	Environmental stressors.	Glare, temperature extremes and low levels of illumination, also includes 'Machine stressors' like unguarded machines at the point of operation, transmission of power and other dangerous parts.
3.	Physiological stressors	Narcotics & Alcohol.

7.6 Ferrell's Human Factors Theory:

Dr. Russell Ferrell, Professor of Human Factors al the University of Arizona, gave this theory of accident causation as shown in diagram below:



This theory states that accidents are the result of a casual chain (as in multiple causation theory), one or more of the causes being human error, which is in turn caused by three situations - overload, incompatibility and improper activities. Factors affecting these three situations are as follows :

1. **Overload** (A mismatch of capacity, load and a state) due to-

(a)	Load	Task (Physical, information processing)
		Environment (Light, noise, distraction, stressors, that requires active coping)
		Internal (worry, emotional stress)
		Situational (Ambiguity of goals or criteria, danger)
(b)	Capacity	Natural endowment, physical condition, safe of mind, training, drugs, pollutants, pressure, fatigue, stressors that impair ability to respond.
(c)	State	Motivational level and arousal level.

2. **Incompatibility** (incorrect response or mismatch) due to -

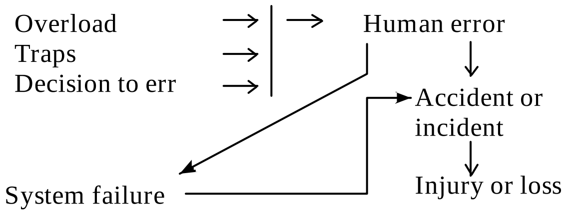
(a)	Stimulus – Response	Due to control – display
(b)	Stimulus – Stimulus	Due to inconsistent display types
(c)	Response – Response	Due to inconsistent control types or locations.
(d)	Work station	Size, force, reach, feel

3. **Improper** Activities due to
   (a) The worker did not know how to do it.
   (b) He deliberately took risk due to
   — low perceived probability of accident
   — low perceived cost of accident

Since this is basically human factor model, greater emphasis is placed on the first two causes of human error, overload and incompatibility.

7.7 Petersen's Accident – Incident Causation Theory :

This theory adapts Ferrell's human factors of overload and (also Heinrich's domino theory and states that causes of accident/incident are human error and/or system failure. Human error is due to overload, traps and decision to err. Human error may directly cause accident or may cause system fa ilure which may cause accident resulting in injury or loss as shown below:



Factors causing overload are much the same in Ferrell's model.

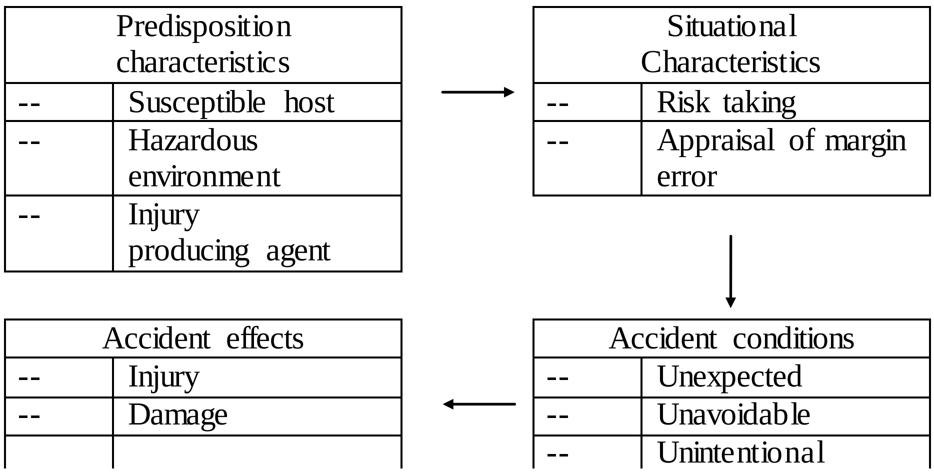
Traps are due to defective workstation, design and incompatible displays or control.

Decision to err are caused by illogical decision under situation, unconscious desire to err and perceived low probability.

System failure is due to error in policy, responsibility, authority, accountability, measurement, inspection, correction, investigation, orientation, training, selection, safe operating procedure, standards, hazard recognition, records, medical and others.

7.8 Epidemiological Theory:

Suchman stated epidemiological definition of accident as "An unexpected; unavoidable, unintentional act resulting from the interaction of host (accident victim), agent (injury deliverer) and environmental factors within situations which involve risk taking and perception of danger". His model is shown below:



This originated from the study of epidemics. Casual association between diseases or other biological processes (accidents) and specific environment are studied. A classic example of epidemiological method was given by Snow who discovered that persons using a particular water supply had a higher death rate from cholera than others. Gordon and McFarland supported that accidental injuries could be studied with the same techniques.

7.9 Surry's Decision Theory:

Jean Surry developed this theory stemming from .the epidemiological model of Suchman. It assumes that by a person's action or inaction, danger occurs to the person. If any negative responses to the question are shown during the danger build-up cycle, the danger becomes imminent. If all replies' are positive, the danger diminishes. A negative response to one of the questions will lead to inevitable injury. An accident can be the result of many different routes through the model (20 routes). There are fewer routes leading to no-injury situations.

7.10 Energy (Release) Theory :

Dr. Leslie Ball, former Director of Safety for NASA, introduced a causation theory. His thesis is that all accidents are caused by hazard, and all hazards involve energy, either due to involvement with destructive energy sources or due to a lack of critical energy needs. This model is most useful to identify hazards and to understand system safety.

Gibson noted that injury to a living organism can be only by some energy interchange. Hence it was suggested that the energy exchange should be considered as the injury agent. The energy exchange resulting in an injury could be mechanical, chemical, thermal, electrical etc. This concept is useful in understanding the way injury is caused and examining the solutions. When a grinding wheel is in stop-position it does not make accident, but if it runs and fingers trapped, it makes accident because of its kinetic energy.

William Hadden, m 1970, explained 'energy transfer or release' as the main factor for accident causation and said that accidents and injuries are caused because of transfer or release of energy between objects, events or environment interacting with people.

Ten strategies were suggested by Hadden to prevent or reduce losses as under:

1. Prevent the transfer or origin of energy, e.g. safe substitution - using toluene instead of benzene, not keeping the car running, dipping instead of spraying, shot blasting instead of sand blasting.

2. Reduce the amount of energy trailer, i.e. drive vehicle or machine at slow speed, reduce quantity or concentration 'of hazardous chemicals.

3. Prevent release of energy, e.g. flameproof electric fitting in flammable area, fall arrester device, dyke to stop spread of .chemical, safe overflow pipe or level cut off device.

4. Change the rate of release or distribution of released energy, e.g. reduce the road slope, use inhibitor to reduce rate of reaction, sprinkler to reduce rate of burning, scrubber to scrub toxic gas, condenser to liquefy organic vapour.

5. Divert (separate) the energy released in time or space, e.g. separate paths for vehicles and pedestrian traffic, keep electric wiring or pesticide out of reach, discharge gases at height

6. Provide barrier between the energy released and a structure or a person likely to be affected, eg. guards on machines, radiation shield, filter, safety goggles, earplugs, insulation on hot surface, blast wall against explosion energy.

7. Make the surfaces of structure safe. e.g. rounded corners, blunt objects, big handles of tools and no sharp edges.

8. Strengthen the structure or person susceptible to damage, e.g. fire resistant wall, training to workers and vaccination for disease.

9. Early detection ,of damage and actuate counter effect, e.g. fire detectors with sprinklers, high level alarm and tripping of feed pump, temperature alarm and starting of cooling system.

10. Speedy measures to restore normal condition, e.g. rehabilitation of injured worker, repairing of a damaged machine or vehicle.

See Part 5 and 6 of Chapter-2 for safety philosophy on accident causation.

8. PRINCIPLES OF ACCIDENT PREVENTION

After understanding the causation of accidents, it is obviously essential to understand the principles and techniques of accident prevention. But before that we will see the types of accidents first.

8.1 Types of Accidents:

Based on severity of injury, accidents are major, minor or near miss type. The combination of injury and property damage gives four types of accident as follows:

1. Injury and property damage (major).
2. Injury and not property damage (major or minor).
3. Properly damage and not injury (major or minor).
4. No property damage and no injury (near miss). Based on causation, they are of five types:
1. **Psychological causes** - such as inexperienced, not motivated for safely, worry, emotional, wrong attitudes etc.
2. **Physiological causes** - such as age, sex, body-build, poor hearing, vision, strength etc.
3. **Physical causes** - such as heavy workloa4, long working hours, no rest, unhealthy work environment, work at height, depth, or in confined space, falling toad etc.
4. **Mechanical, Electrical, Chemical, Radiation causes** - such as unguarded machinery, defective equipment, noise, vibration, obstructed pathway, sharp edge, electric shock, static electricity, chemical, poison, toxic gas, acid, fire, explosion, radiation etc.
5. **Environmental causes** – Weather effects, heat, cold, humidity, air, wind, ram, tyde, lightening etc.

Causes of type No.1 and 2 give rise to unsafe action while No. 3 to 5 give rise to unsafe conditions.

8.2 Fundamentals of Accident Prevention:

As explained by Heinrich, accident prevention is both, science and art. It represents control of performance of man, machine and physical environment.

The word 'control' includes prevention as well as correction of unsafe conditions and actions. Prevention is the first or initial part of 'control' which if practised, subsequent control for consequence or effect may not be needed. Thus accident control is a vital factor in every industry, which if ignored or practised unskillfully, leads to needless human suffering and business bankruptcy.

The accident-prevention task requires both, the short term approach (direct control of personal performance and environment) and the long-tern approach of instruction, training and education. This task must be performed before an accident and injury occur. Subsequent efforts after accidents are also necessary.

Thus accident prevention may be defined as an integrated programme, a series of co-ordinated activities, directed to the control of unsafe acts and unsafe conditions and based on knowledge, attitude and ability for safety. It aims to serve industry, country and humanity.

Five basic or fundamental steps for accident prevention (safe and efficient production), suggested by H.W. Heinrich, are:

1. Organisation.
2. Fact finding.
3. Analysis of the facts found
4. Selection of remedy and
5. Application of the remedy.

Sixth step of 'Monitoring' (i.e. measurement o: result, assessment i.e. comparison with legal criteria or standard, feedback and further improvement) is also suggested. Such review is necessary after all safety progrmmes.

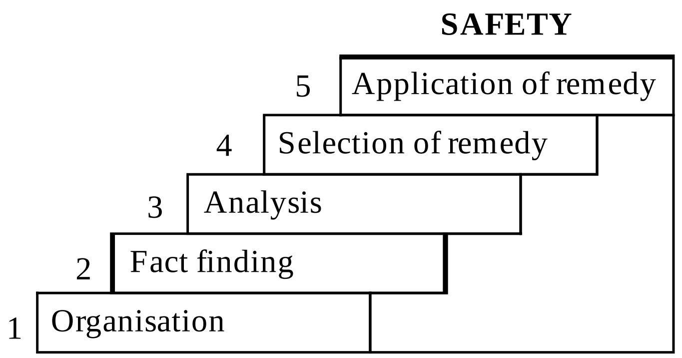


Fig. 4.7 Steps of Accident Prevention

8.2.1 Organisation:

As shown in Fig. 4.7, organisation is the first step of accident prevention ladder.

The safety organisation, management or at least the planned procedure, which it represents, is the vehicle, the mechanism by means of which interest is kept alive and the safety programme is designed, directed and controlled. The actual work of prevention is done by safety director or manager, safety officer and the line and staff supervisors with the active support of top management. See Chapter-6 on safety management.

Safety is not only a staff function but it is a line function also. Budgetary provision (cost allocation) for safety should be made from very beginning.

Here organisation does not mean safety department only. Safety is not a function of one department only. All the members of organisation (including all departments) have to contribute and play their role for safety.

Basic philosophy and safety policy for accident prevention and firm determination of the top management are utmost necessary.

Organisation also includes single person working for safely.

8.2.2 Fact Finding:

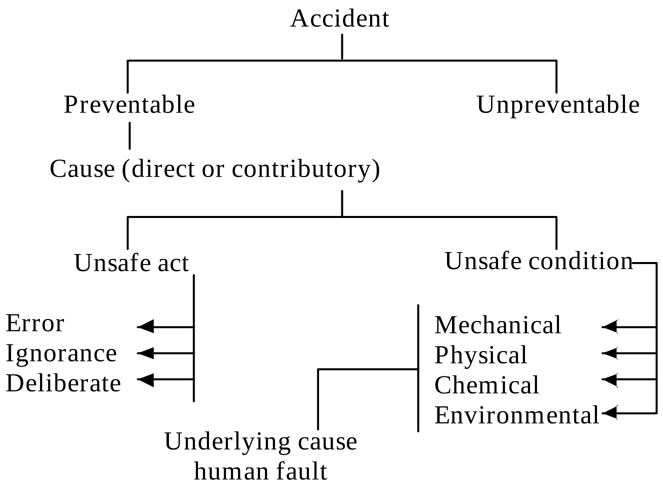
The knowledge of probable or potential hazards (facts) is derived from surveys, inspections, safety audits, observations, review or records, inquiry, investigation and judgement.

Facts include past, present and future facts which have caused and which can cause accidents Past causes can be known by 'accident records' and inquiry. Future (hidden) causes can be known by HAZOP, HAZAN, safety audit, inspection etc.

The term "hazard" is synonymous with the phrase "direct and proximate accident cause" i.e. the unsafe personal act and/or unsafe physical mechanical, electrical, chemical, environmental condition without which no accident can occur.

Personal hazards (unsafe acts) are violations of commonly accepted safety rules, practices and procedures. Mechanical hazards (unsafe conditions) are of four groups: Static, kinetic, electrical and chemical (including radioactive or nuclear).

Heinrich classifies main causes of accident as under:



The proximate cause is the nearest in 'efficiency' rather than whether it was closest in time or not.

13 unsafe acts and 13 unsafe conditions are listed in foregoing Part 7.1 entitled 'Heinrich's theory of accident causation'. These are some general heads or categories under which more specific acts may be grouped. For example, the general head "Making safety devices inoperative' can be sub-itemised as:

1. Removing guards.
2. Tampering with adjustment of guard including making interlock guard inoperative.
3. Beating or cheating the guard.
4. Failing to report defects etc.

Two types of main facts - unsafe acts and unsafe conditions – are discussed below.

(1) Unsafe Acts:

Unsafe act is a human action resulting in accident or injury to him, others, environment or all. See also Part 3.94 of Chapter - 2 for definition of 'unsafe act'.

Some reasons of unsafe acts are as under:

1. **Improper Attitude -** Wilful disregard, reckless, lazy, disloyal, non co-operative, fearful, oversensitive, egoist, jealous, impatient, absentminded, excitable, obsession, phobia, inconsiderate, intolerant, mentally unsuited and other psychological reasons.

2. **Lack of knowledge or skill -** Insufficiently informed or trained misunderstands, not convinced of need, indecision, inexperienced etc.

3. **Physically Unsuited -** Due to hearing, sight, age, sex, height, ill, allergic, slow reaction, crippled, intoxication, physically handicapped and other physiological reasons.

4. **Physical conditions -** Space, light, ventilation, heat, layout or arrangement, materials, tools, equipment, procedures, company policy, routing etc. make it awkward, difficult, inconvenient, embarrassing or impossible to follow safe practice rules.

Unsafe act should be noticed as early as possible and removed just after it is noticed. Purpose should be of removing injury, to prevent recurrence and not to punish any individual.

Workers should be properly observed for their unsafe act by seeing their selection and use of –

1. Position of their standing and working.
2. Tools and equipment including hand tools, power tools, lifting tools, PPE, FFE etc.
3. Method or procedure adopted by them.
4. Traffic arid driving rules.

Position and working should not be in dangerous conditions. Tools and equipment should be of correct size and type, should be used correctly and in right condition. Procedure or method should be safe and adequate. Where safety work permit is required, it must be explained and followed correctly. Driving should be safe or defensive and traffic rules must be followed. Drivers of vehicles of hazardous goods should have undergone specific training.

After seeing an unsafe act, observer's (e.g. supervisor or safety officer) attitude should be to 'talk with' the worker and not to 'talk to' the worker. This means to call or advise the worker politely, ask him why he is doing so or not using required tool, equipment, procedure etc., hear his explanation, try to understand him and then explain him the 'underlying hazard' and make him convinced about 'unsafe act' and to correct it as per safety requirement.

Some examples of unsafe acts and control measures are given in **Table 4.1:**

Table 4.1: Unsafe Acts, Remedies and Responsibilities

	Unsafe Actions or Behaviouristic Causes		Remedies		Responsibilities
1	Age, sex, experience		Proper selection of personnel		Personnel Dept.
2	Physical and physiological conditions such as work-load, physical strain, physical weakness, headache, cold, faintness, abnormal blood pressure, poor vision, handicapped, deaf, dumb, epilepsy etc.	A	Workload study and proper distribution	A	Supervisor, Safety Officer
		B	Pre-employment medical exam.	B	Physician, Factory Medical Officer
		C	Periodic medical exam.	C	Physician, Factory Medical Officer
		D	Proper selection & placement of person	D	Personnel Dept. and Psychologist.

3	Poor attitude and inability such as inattentive, insubordinate, un-cooperative, critical of supervision, bad skill or motives, wrong habits, intoxication, chance taking, absent minded, disregard of safety rules & instruction etc.	A	Pre-employment psychological or ability tests	A	Personnel Dept. and Psychologist.
		B	Supervision	B	Supervisor
		C	Discipline	C	Supervisor and Personnel Dept.
		D	Personnel work	D	Personnel Dept.
4	Human errors such as intentionally performed, due to – behaviour Components, personal factors, situational factors,, and lack of knowledge, training etc.	A	Mechanical, electrical, physical, chemical safeguards and safety rules	A	Safety & other Engineers
		B	Safety education, training, meeting, contest, posters, maintaining interest and awareness.	B	Supervisor and Safety Training Dept.
		C	Job analysis and revision	C	Production and Safety Manager.
5	Emotional factors such as worry, hurry, fatigue, accident proneness or tendencies, home or social difficulties, loss of sleep, periodical emotional disturbances etc.	A	Pre-employment tests	A	Personnel Dept. and Psychologist.
		B	Supervision	B	Supervisor
		C	Maintaining interest and awareness	C	Supervisor and Safety Officer
		D	Critical incident technique	D	Expert

(2) Unsafe Conditions :

See Part 3.95 of Chapter - 2 for definition of 'unsafe condition'.

Unsafe condition is created by an unsafe act of a person or act of God or by any agency or due to failure or weakening of any material, structure, situation, condition or system.

Observance of unsafe conditions includes many areas such as proper lighting, ventilation, housekeeping, floors, platforms, handrails, toe guards, machine guards, tanks, vessels and pipelines, safety fittings and devices, electrical hazards, fire prone condition, gaseous and dust exposures, noise, vibration, heat or atomic radiation, loading, unloading and transportation etc.

Such unsafe conditions are due to non-provision, non-maintenance, poor-maintenance, poor-supervision, lack of training, improper design and layout of plant & machinery, poor lighting, poor ventilation, absence of guards and safety devices, failure of safety devices, equipment or tools, unsafe structure, poor housekeeping, fire-prone area, sources of ignition, static electricity, slippery floor, high noise, vibration, radiation etc.

Observation for unsafe working conditions should include basic techniques of look, listen, smell and feel (LLSF) to detect unusual condition of situation, position, noise vibration, odour, temperature, pressure, out of control etc.

Some examples of unsafe conditions and control measures are given in Table 4.2:

Table 4.2 : Unsafe Conditions, Remedies and Responsibilities

	Unsafe Actions or Environmental Causes		Remedies		Responsibilities
1	Atmospheric conditions such as contents of air, temperature, humidity, ventilation, rain, lightening etc.	A	Air sampling, monitoring, cleaning and conditioning.	A	Engineering and utility Dept.
		B	Humidity Control.	B	Humidity or Engg. Dept.
		C	Improve natural and artificial ventilation by efficient exhaust systems.	C	Engineering Dept.
2	Illumination, its distribution and diffusion – direct glare, reflected glare, shadow and colour	A	Improve natural and artificial illumination.	A	Lighting or Engg. Dept.
		B	Good design and plant layout.	B	Plant Engineer
		C	Proper colour	C	Colour expert
3	Workspace, overcrow ding, obstruction etc.	A	Proper spacing, area, height machinery layout, headroom.	A	Plant Engineer, Civil Engineer.
		B	Good design and housekeeping.	B	Plant Engineer, Supervisor
4	Bad housekeeping, rubbish, disorder, unplanned layout	A	Good housekeeping, orderliness, cleanliness, planned layout.	A	Plant Engineer, Safety Officer
5	Inherent properties and design defects of materials, machines, equipment, buildings etc.	A	Good design, good materials, good construction & maintenance good procedures conforming to standards.	A	Design Engineer, Plant Engineer, Safety Officer, Purchase Dept.
6	Improper guarding like no-guard, inadequate guard, no maintenance etc.	A	Regular inspection.	A	Supervisor, Safety Officer
		B	Include guards in original design order & contract.	B	Chief Engineer, Purchase Engineer, Safety Officer
		C	Provide and maintain guards for existing hazards.	C	Supervisors.
7	Defective materials, tools, equipment, vessels, stairs, pits, tanks, objects etc.	A	Regular inspection.	A	Supervisors
		B	Preventive and corrective maintenance.	B	Maintenance Dept.
		C	Good source of supply.	C	Purchase Dept.
8	Unsafe methods, procedures etc. resulting in unsafe condition.	A	Job safety analysis	A	Production or Plant Manager, Safety Officer
		B	Job training	B	Training Officer, Supervisors
		C	Safety rules & procedures.	C	Dept. Head & Safety Officer
		D	Inspection and Correction.	D	Supervisor, Safety Officer
9	Rate of Production	A	Proper speed of work.	A	Production Manager
		B	Time study, Motion study, job study, machine study etc.	B	Supervisor, Safety Officer
10	Noise & Vibration	A	Noise measurement & controls.	A	Plant Engineer
		B	Use of ear plugs, ear muffs etc.	B	Supervisors, Safety Officer
		C	Vibration detection & controls.	C	Plant Engineer, Supervisors
11	Long working hours or excessive workload	A	Supervision	A	Supervisors
		B	Regulation of Law.	B	Personnel Dept.
12	Insufficient or improper	A	Provide sufficient & good	A	Personnel Dept., Chief

	welfare facilities, clothing, PPE etc.		facilities of toilet, urinals, washroom, lunch room, canteen etc.		Engineer
		B	Provide safe clothing & PPE.	B	Personnel Dept. Supervisors.
13	Hazards in chemical industries, processes, storage, transportation etc.	A	Detection of hazards by various techniques.	A	Supervisors, Safety Dept. Technical Dept.
		B	Application of appropriate remedy such as safe guards & fittings, safety devices, elimination of hazard, minimization of hazard level, lockouts, trips, alarms & interlocks, isolation, fail-safe design, failure minimization, failure rate reduction, screening, scrubbing, monitoring i.e. sensing, measuring, responding, and warning (audiovisual) of dangerous parameters, remote controls, microprocessors, recorders, auto controllers etc.	B	Chief Engineer, Plant Engineer, Production Engineer, Chemical Engineer, Supervisors, Safety Officers.
14	Emergencies & Disaster	A	Onsite Emergency Plan	A	Chief Executive, Safety Officer, Fire Officer, Emergency Staff
		B	Offsite Emergency Plan	B	Govt. authorities, mutual aid members, associations etc.
15	Act of God and unexpected events	A	Assessment and safe planning.	A	Design Engineer., Top Management
		B	Onsite Emergency Plan.	B	Chief Executive, Safety Officer, Fire Officer, Emergency Staff

Facts from Accident Reports:

Form No. 21, 21A and 29, under the Gujarat Factories Rules and Annex -13 under the Electricity Rules prescribe some facts for accident reporting which should be referred for information.

Facts should include 'past facts' of accidents already happened and 'future facts' of possible accidents based on various hazard identification techniques such as Hazop, Hazan, risk assessment, FTA, ETA, etc as stated in Part 4 of Chapter - 19.

8.2.3 Analysis of the Facts :

The third step to accident prevention is analysis of the facts found. This is defined as the work of drawing conclusions from assembled data. The hazards are here named, identified and classified or analysed. Such work is done by (a) Analysis of past experience (b) Survey and inspection (c) Judgement and experience plus enquiry. Identify the direct causes, sub-causes, underlying major causes, types of accident, operations, tools and equipment obstacles, frequency, severity, location, occupation etc., and classify them.

The supervisor's report of accident investigation is the basis of all analysis of past and present accidents. It is the most important, difficult and skilful task requiring good knowledge and experience. Decide very carefully that which is the unsafe act, which is the unsafe condition, which is more proximate and the accident is due to any one or their combination and in which sequence. From facts, witnesses and rational judgement find reply to all these questions and report properly for real accident reporting and true causation study.

Twelve steps (safety officer's procedure) to analyse the causes of accidents are as follows :

1. Obtain the supervisor's report of the accident containing the details given above.
2. Obtain statutory accident report form.
3. Obtain the injured person's report.
4. Obtain the reports of witnesses if any.
5. Obtain the doctor's report on injury. .
6. Investigate the accident.
7. Record all evidences and facts.
8. Tabulate the essential facts of the accident together with the similar past accidents.
9. Study all the facts.
10. Analyse accident causes in details. Such analysis will classify causes as defective or no guard, poor lighting, poor ventilation, no safety devices, no use of PPE, accidents - fatal or nonfatal, male or female wise, day or night wise, age wise etc.
11. Arrange the causes in order of importance or priority of compliance.
12. Find and record reasons of existence of those causes.

After finding potential hazards, cross analysis of records must be made to select most important hazards or targets. Reasons for existence of hazards must be found for correction.

Appraisal, analysis, inspection and control techniques are separately discussed in details in Chapter-19.

8.2.4 Selection of Remedy:

When it is analysed to indicate, which is the proximate or main cause that needs to be corrected then it suggests the fourth step of selection of remedy for the named (analysed) hazards. Four basic remedies 'are as under:

Four Basic Remedies:

1. **Engineering Controls :** Guarding of machine and tools, isolation of hazards, revision of procedures and processes, good illumination, ventilation, colour and colour contrast, substitution of safer materials and tools, replacement, reduction, repair and a variety of mechanical, physical and chemical remedial measures for which the most of the chapters of this book are developed.

2. **Instruction, Training, Persuasion and Appeal:** Regular training as well as instruction, reinstruction, persuasion, appeal, notice, posters, supervision and motivation.

3. **Personnel adjustment:** Selection and placement with regard to the requirement of the job and the physical and mental suitability of the worker, medical examination, treatment, advice and PPE. 4. Discipline: Mild admonition, expression of disappointment, fair insistence, statement of past record, transfer to other work and penalties.

In the process of selecting an effective remedy, 'Engineering Control' takes the first place and discipline as the last resort. Select the most effective and urgent remedy first and then precede priority wise.

8.2.5 Application of the Remedy:

The final step in accident prevention is application of the selected remedy.

If machines, tools, vessels, equipment, structures, procedures etc., are unsafe, they must be guarded, ' replaced, revised or otherwise made mechanically safe or accident free. This is management's responsibility. The safety officer/engineer will guide and the supervisors see to it that the necessary work is done.

If the personal performance is unsafe, employees must be selected, instructed, trained, cautioned, persuaded, convinced and appealed for improvement. Certain cases require proper placement, other medical or psychological treatment or advice. In rare cases and as a last resort, some form of disciplinary action may be needed.

Application of selected safety measures should be immediate and long-term. Existing unsafe conditions and actions should be corrected at once while at the same time long-term programmes should be started to include procedures and techniques devised to anticipate and prevent situations of a similar nature.

Application of remedy is the dynamic part of accident prevention. Unless the remedy is successfully applied, all prior steps are of no use and wasted.

(1) **Ways & Means of Application of Remedy:** A safety engineer or officer applies the following ways :

1. Prepares, presents and applies recommendations, suggestions summaries and plans.
2. Establishes a safety organisation.
3. Gets support of management and supervisory staff in applying the remedies.
4. Creates enthusiasm and co-operation up and down the line.
5. Satisfies himself by seeing the successful working of the remedies applied.

He will apply in chronological order the four basic remedies mentioned in the foregoing Part 8.2.4. Engineering controls call for designing, buying and building, installing and maintaining guards, safety devices and safety equipment. The persuasion and appeal remedy requires teaching, training, appeal, instruction, persuasion etc.

He must have ability to overcome obstacles in applying remedies. He should identify the obstacles as a person, attitude, condition or circumstance.

Constant follow-up action through safety administration is necessary. Detection and placement of physically impaired workers should be carried out carefully and effectively. In a typical one-man plant the employer himself has to carry out all such functions single-handedly. All employees are expected to work safely. Responsibility should be fixed and distributed for quick compliance. A supervisor or foreman is the key-man for such purpose.

Machine - accidents are controlled by effective engineering-revision. But many accidents take place in material handling for which two highly successful methods may be employed, (i) One lies in the study and improvement of methods and procedures to the end that some safer and better way or equipment may be found to conduct any particular operation than that in use. (ii) Secondly, it is most useful to utilise the proper degree of supervision - from the chief executives down to the foreman - that will result in the observance and correction of unsafe material handling practices on the part of the workers before injuries occur.

(2) Creating and Maintaining Interest:

The second basic remedy of persuasion, appeal, instruction and training requires vast efforts. The practice of creating and maintaining interest for accident prevention applies to employers as well as employees.

Group interest of employees is created and maintained by the safety organisation which includes moral and educational effect of accident investigation, publicity, posting and distribution of educational literature, safety films and slides, contests, prizes, awards, meetings and inspirational talks. See part 8.4 and 8.5 of Chapter -3 and Part 8.2.4 of Chapter -6.

Individual interest of employees is created and maintained by an appeal to personal characteristics listed below:

1. **Self-preservation** (Fear of personal injury) Featuring the injury by figures, posters, notices, meetings, oral discussion, lectures, films and slides are useful to maintain the strongest and commonest human instinct of self-preservation or self-protection.

2. **Personal and material gain** (Desire for reward) Bonus, salary increase, vacation with pay, days off, trips, personal gifts, requisite assignments of work,, banquets, picnics and participation in safety activities prove useful in this regard.

3. **Loyalty** (Desire to co-operate) Effect of accident by the employees on supervisor's record, on employer's overhead cost, on quality of product, on fellow employees and on company's prestige must be brought to the notice of individual to create and maintain their sense of loyalty to the employer.

4. **Responsibility** (Recognition of obligation) The sense of responsibility, both to self and to others, is created by assignments and analogy of observance of safety rules.

5. **Pride** (Self satisfaction and desire for price) Pride increases ability to work. Praise exhibits, awards and insignia, differentiation of workers having outstanding safety record by giving them special hat/dress, reward etc., are useful in this regard.

6. **Conformity** (Comparison with standards or good examples) Some methods of appeal are: Standards (Safe practice rules, codes, procedures etc.), comparison, system and regularity, leadership of good example in safe conduct, ridicule, etc.

7. **Rivalry** (Desire to compete) Man is a highly competitive animal and creates better results when competing with other than when working alone. For this, provide opportunity, set up objectives and determine method of measurement

8. **Leadership** (Desire to be outstanding) The desire for leadership is strong in many persons which may be used to advantage in safety work. Such persons should be given additional responsibility in safety work and promotion etc.

9. **Logic** (Special ability to reason) Some persons have special ability to see both sides -of a question and to arrive at conclusions that are logical and just. Such persons should be used in safety work. A few methods of appeal to logic are basic philosophy of accident causation and prevention,

providing data relating to accident frequency, seventy, types and causes of accidents and remedial measures.

10. **Humanity** (Desire to serve others) Humanitarianism is a widely spread human instinct and strong appeal to everybody for safe performance. Safety is termed as Human Engineering on this ground where human is expected to be at centre. We have to fit the unfit to survive.

(3) Education:

All accident-prevention work is basically educational. Well-trained and careful men may avoid injury on dangerous work and untrained and careless men may be injured underlie safest possible conditions.

Safety education is meant to include meetings and talks, personal contacts with authorities or teachers, use of bulletins, posters, lectures and reading material, slides and films, computers, first-aid instruction and any oral or written instruction for avoiding hazards and cultivating safe methods of doing work.

Some of the most commonly used educational procedures are listed below:

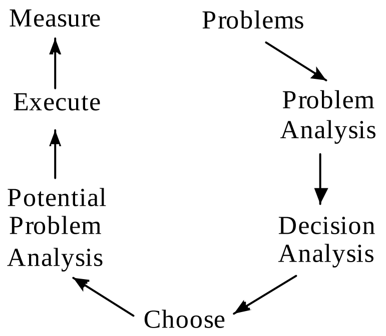
1. Regular safety coaching class for workers. Hazards, safety precautions, safety measures, safety duties and procedures should be explained in their own language.
2. Periodical safety class for supervisors, managers and top executives for co-ordinated efforts from all.
3. Safety meeting, conference, seminar, exhibition etc.
4. Publicity-Safety posters, slogans, maxims, notices, bulletins, pay-pocket-inserts, stickers, slides, films, house magazine etc.
5. Safety books, pamphlets, periodicals etc.
6. Safety contests, essays etc.
7. Safety plays and similar programmes.
8. Preparation of safety codes, standards etc.
9. Use of loyal employees in setting a good example.
10. Safety message on work orders, computers, correspondence etc.
11. Featuring specific safe-practice rules.
12. Investigation of accidents and explaining their analysis of unsafe actions, unsafe conditions and their remedial measures.
13. Conducting training programmes.
14. Sending persons to outside safety courses.
15. Specific programmes as per our own need and nature of work.

16. Conducting short-term safety course for all employees in rotation.

8.3 Models for Accident Prevention:

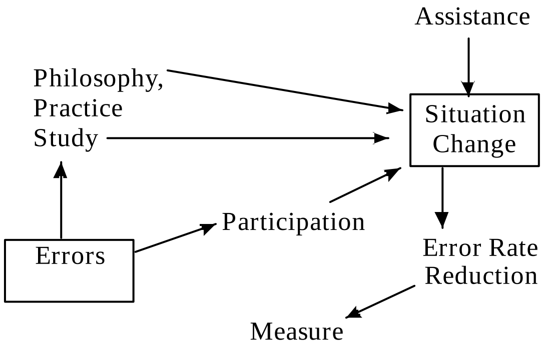
H.W. Heinrich's model of 'Five steps of accident prevention' is explained in previous Part 8.2 and shown in Fig. 4.7. The other relevant 'models given in Heinrich's book (ref. no. 1) are explained below in brief.

8.3.1 Kepner-Tregoe Model:



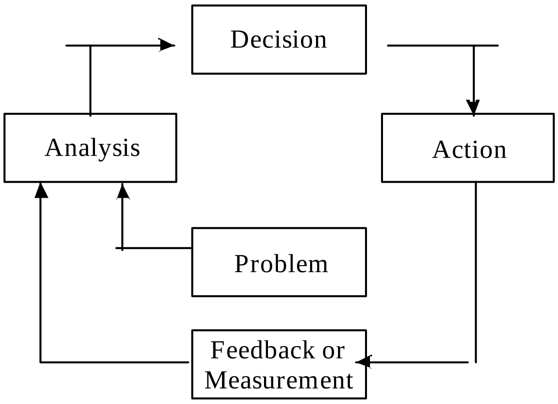
This model is very close to Heinrich's five step model shown in Fig. 4.7. 'Execute' means application of remedy. 'Measure' is a new step in this model, requiring measurement and monitoring of the execution.

8.3.2 Improving Human Performance (Error Reduction) Model :



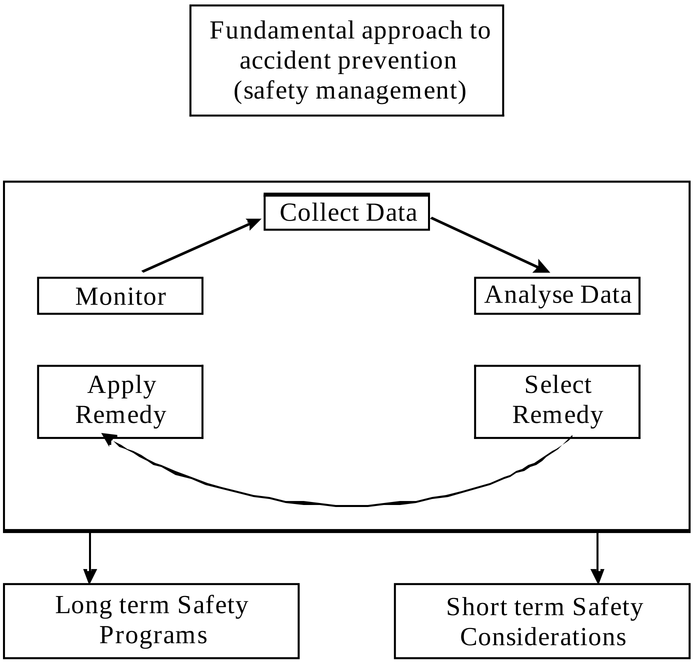
This model is discussed by Johnson in MOR1 (management oversight risk tree). Here errors are considered inevitable, situations error-provocative, rate of error measurable and reducible. Situation can be changed by study, practice and participation.

8.3.3 Performance Cycle Model :



Johnson has discussed this model in his MORT. Here five steps in sequence are problem, its analysis, decision, action and measurement of result. If may be again analysed for re-decision.

8.3.4 Updated Safety Management Model:



This is updated model of Heinrich's five steps model shown in Fig. 4.7. Here only one step of 'monitor' is added for monitoring of applied remedy and to reconsider the problem.

Basic philosophy of accident prevention is required at the root of any safety management. Monitoring is a feedback mechanism, it tells us how we are doing, what progress we are making. It dictates additional needs, we then collect additional data, analyse it, select additional remedies, apply them, monitor and so on.

8.4 Five 'E's of Accident Prevention

Safety or accident prevention can be achieved by the following five methods:

1. **Education & Training**
   (To prevent unsafe acts)

This has long-term and permanent effect. This is the most powerful remedy for unsafe act of the workers. It helps in finding out unsafe conditions also. The workers' safety training programmes should include (a) Understanding of specific hazards of then plant, process, building etc. (b) Safety rules and safe procedures (c) Training for specialised or difficult job (d) Job safety analysis and (c) Safety instructions for variety of jobs.

2. Engineering controls
(to prevent unsafe conditions)

Poor illumination and ventilation, unguarded machinery, mechanical, electrical, physical and chemical hazards, dangerous location or situation etc., are unsafe conditions which can be eliminated in the design stage or subsequent engineering revision and controls. This is the first and most effective remedy.

Some engineering controls are- substitution of less hazardous material, machine, method, process, vessel etc., risk reduction, process modification, isolation, segregation, guarding, fencing, barricading, enclosure, dilution, safe design; failsafe device and safety devices including alarms, trips, safety valve, NRV, PRV, EFV, FFE, etc.

3. Enforcement (of safety rules)

All statutory safety provisions should be followed for our own safety and safely of others. Self initiation for full compliance is necessary, otherwise government authorities may take action. In addition, other safety rules for our plant should also be framed and followed. Wilful neglect or disobey of safety rules or orders should be dealt with strictly.

Enforcement measures include - new law, amendment in old law, company safety rules, implementation and legal action.

4. Enthusiasm (to maintain interest)

Like a catalyst it adds to safety awareness and motivation. It should come from the top management to the lowest worker. It will keep the workers safety conscious. It can be developed and maintained by proper safety attitude, competition, prizes, awards, publicity, incentives etc.

This includes motivation and participation in safety programmes.

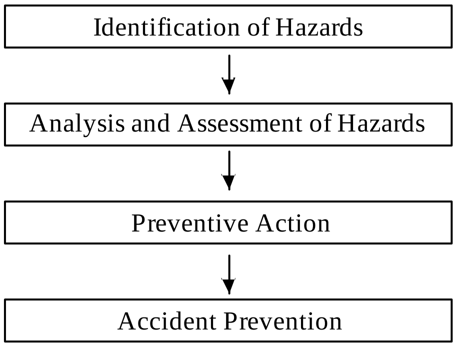
5. Example setting (to lead for safety)

The top executives, managers and supervisors should set an example to others by the self-enforcement of safety rules. Then others will follow them. This is a chain reaction to increase and maintain safety.

8.5. Approaches to Preventive Action:

Mainly there are two types of approaches.

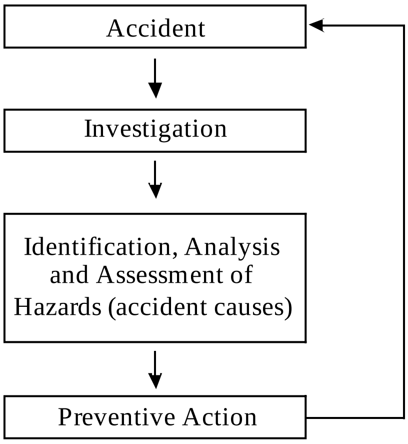
(1) **Proactive or Preventive Approach**
(Effort before accident)



In proactive or preventive approach, action is to be started without waiting for accident. Potential hazards are first identified, analysed and preventive programme is formulated to' remove or reduce the hazards identified. This approach is better then the reactive approach, but it incurs regular costs.

(2) Reactive or Corrective Approach

(Effort after accident)



Normal habit of a person or management is to follow this reactive or corrective approach only after an accident. They do not think to invest money or time for preventive measures to avoid accidents by advance planning. Drawback of this approach is to suffer some loss due to one or more accidents. In this approach, action is started after accident. Accident causes are investigated analysed and preventive action is determined. Then it is applied to prevent recurrence of the similar accident. This works as a lesson from the accident.

E X E R C I S E

1. Comment on the following Statements by giving your opinion:

1. Accidents are accidents. They just happen. They cannot be caused or prevented.
2. We prevent accidents because it is our legal duty.
3. Productivity is more important than safety.
4. Safety obstructs productivity OR Safety retards production.
5. Safety and productivity are two sides of a coin.
6. Legally 'accident' is not possible without injury.
7. ‘Accident is also possible without injury or damage.
8. Prevention of near miss is more important than to prevent 'accident'.
9. Heinrich’s ratio theory is meaningless. Accident does not give any warning or opportunity to prevent it.
10. 88% accidents occur due to unsafe acts of the workers. Therefore there is no meaning in wasting money to improve ‘unsafe conditions’.

11. Accident happens due to multiple causes, not by any single cause.
12. Energy transfer is the main cause of accident.

13 Organisation is the first step of accident prevention.
14. In accident prevention work, search of ‘past facts’ (accident record) and ‘future facts’
15. ‘Engineering control’ is the best remedy.
16. Without application of the remedy, other efforts are helpless.
17. All accident prevention work is basically educational.
18. Reactive approach is preferable to proactive approach.
19. Supervisor should 'talk to' the worker and not 'talk with' the worker to explain his unsafe act.
20. Feedback or measurement of result is useful in 'performance cycle model' to correct our preventive action.

2. Write Short Notes OR Explain in brief:

1. The accident problem.
2. Need for safety.
3. Reasons for accident prevention.
4. Factors impeding safety.
5. Meanings of 'Accident'.
6. Types of 'Accident'.
7. Types of Injury'
8. Types of 'Dangerous occurrences'.
9. Types of 'Dangerous operations'.
10. Types of 'Hazardous process'.
11. Notifiable diseases.
12. Ten Axioms of industrial safety.
13. Accident sequence.
14. Criticism of Heinrich's theory.
15. Facts finding for accident prevention.
16. 'Unsafe acts' OR 'unsafe conditions'.
17. Four basic remedies for accident prevention.
18. Ways and means to apply remedy to prevent accidents.
19. Updated Safety Management Model.
20. Two approaches to safety.

3. Discuss with details:

1. H.W. Heinrich's Theory OR Frank Bird's Domino Theory.
2. Multiple Causation Theory OR William Hadden's Energy Theory.
3. Five Fundamentals of Accident Prevention.
4. Five 'E's of Accident Prevention.

CHAPTER – 5

Safety Statistics and Information System

THEME

1. NATURE, SOURCE AND NEED OF STATISTICS OF SAFETY

Nature:

'Statistics of safety' is a wider term expecting many data. Mostly it includes 'accident statistics' and 'costs of accidents', but it may also include measurement of safety performance and labour turnover, safety activity rate, cost of accident prevention and modern approach to measure the problems of safety. The cost of accident includes a variety of direct and indirect costs which emphasise the need of safety. An accident is a great loss to the person injured, his family, his employer or factory and tile society at large. How to measure all such losses is a real problem of statistics oLs&fety.lS:3786-1983 prescribes some methods of computation.

Source :

At present the major source of our labour statistics is the Labour Bureau, Shimla, which is the main body under the Ministry of Labour, Govt of India compiling and publishing various labour statistics of India through its many publications. It regularly conducts training classes to teach such statistics which is highly useful to all labour and safety people. Other agencies are National Safety Council and Central Labour Institute, Mumbai and Offices of the Labour Commissioners and Factory Inspectorates of all States and Union Territories. Some Industrial Extension Bureau such as INDEXTb in Ahmedabad also publishes good statistical reports. Figures and Tables given in this Chapter are taken from the publications of these sources. .Statistics of road-and other accident can be had from police and transport offices.

NOW a days websites are also available.

Need or Utility of Data:

Why do we need safety statistics or measurement of safety performance? This basic question has following basic replies :

1. It is the basic force of the organised safety movement
2. It is useful to all management to calculate their accidents costs. The management must realise that indirect (hidden) cost of an accident is 4 to 8 times more than the direct cost. This cost saving factor can motivate them for prevention of accidents, injuries and property losses.
3. The statistics is useful in comparing ourselves with others in relation to safety records. This leads us to better safety performance and safety records.
4. It properly emphasises that accident prevention is economical and productive rather than humanitarian.
5. It promotes safety in all walks of life like road safety, home safety, industrial safety and safety at the sea and the sky.
6. It equally opens the eyes of workers and their unions in really understanding their accident problems and losses to them. Actually, the workers are the first and most sufferers of accidents or injuries the statistics of which explains them the importance and gravity of the problem.
7. The Government is paying lakhs of rupees every year in terms of workmen compensation and other benefits. Many insurance companies also pay the huge amount for accidental injuries, deaths and property- damage. If they know the real statistics of accidents or losses, they may try to suggest necessary safety measures to reduce the premium amount.
8. Reliable cost information is* A basis for decisions upon which efficiency and profit depend. Some proposed measures may be accepted or rejected on the basis of their probable effect on profits.
9. Most executives wish to make their companies safe places and run their business profitably. Information on the cost of accidents enable them to estimate the savings which can be effected through investment for accident prevention.
10. Monthly reports showing the cost of accidents or the savings due to good accident prevention efforts is an important means of motivating attention to safe operating conditions and procedures.
11. Accident statistics give clear classification that what are the main causes of accidents, which are the main departments of accidents, what are unsafe areas or conditions, what are unsafe actions, how much is the money-loss and time loss in accidents etc., so that we can easily concentrate upon those areas and provide remedial measures to stop those losses. This is the greatest advantage of safety statistics.
12. The altitudes of workmen and of society become unfavourable when accidents are frequent or. affecting public at large as in case of Bhopal disaster. An unfavourable attitude invariably influences production, sales etc. The realisation of such indirect costs or public compensation serves as motivation for management to prevent accidents. It is also a warning to the unsafe

13. Safety statistics shows the need and methods for standardised data about accidents, injuries, failure rates of equipment etc. and costs. Indian Standard IS:3786 provides method for computation of frequency .and severity rates for industrial injuries and classification of industrial accidents. The statistics is also useful in preparing, presenting and communicating reports on safety performance.

14. Accident statistics provide valuable information to regulatory agencies and insurance companies. Regulatory agencies may use such data to identify causative factors and additional safety requirements to prevent future accidents. Insurance companies can use the data in determining costs of premiums which are based on accident and injury frequencies and severity rates.

15. Accident statistics are essential for planning accident-prevention activities, assessing their effectiveness and amendment of safety laws.

2. MAGNITUDE OF THE PROBLEM AND INADEQUACY (LIMITATION) OF DATA

Let us try to understand the problem by some available data:

India :

In our .country, in 1994, there were total 190435 accidental deaths (See Table 5.7) of which majority were road and rail accidents and due to fire, drowning, poisoning and miscellaneous causes. The factories and mines accidents were 606 and 506 respectively. Percentage wise major causes-were: Road accident 27.2, Fire 12.2, Drowning 12.1, Railway accident 9.6, Poisoning 7.2, fall from height 12, Electrocution 1.8, others 9.2 and unspecified causes 18.5. This is shown in Fig. 5.1. Almost similar are the figures for 1993 and 1992 (LP News, 1996). Thus fatal industrial accidents are less than 1% of the total accidents in the country.

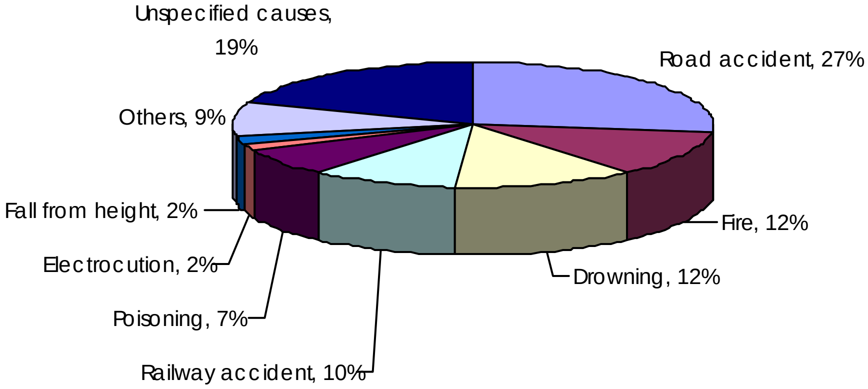

Fig. 5.1 : Fatal accidents in 1994

In 1990, there were total 663 fatal and 127454 non-fatal factory accidents in India, which were 784 and 253184 in 1986, respectively.

Under the Workmen's Compensation Act, in 1992, there were 1503 deaths, 1365 permanent disablement 7377 temporary disablement reported land amount of compensation paid for them were Rs. 807.43 lakhs, 233.36 lakhs and 113.55 lakhs respectively.

Under the Employees' State Insurance Act, in 1992-93, the figures areas follows :

No. of factories covered	150349
No. of employees in factories covered	6691000

No. of family units covered	7444000
No. of beneficiaries covered	28883000
No. of cases admitted in hospitals	3777904
Home visits paid	184148
Medical benefits paid (total)	Rs. 8329 Lakhs
Dependants benefits paid	Rs. 1211 Lakhs

Above figures are not the complete picture, because, many accidents might not be reported and many factories are not covered under the ESI Act.

UK:

As per the Robens Report, the figures of 1969 were as follows:

Subject	Number	Cost Million Pound
Fatalities in industries	1918	20.20
Fatalities in factories	649	8.28
Industrial accidents	841680	96.90
Factory accidents	441630	54.70
Total industrial accident cost		336.30
Total factory accident cost		133.90

USA:

In 1965, the total cost of accidents at work, home and roads was estimated 18030 million dollars.

The National Safety Council estimates that the annual costs resulting from injuries and deaths plus losses in motor vehicle mishaps and fires, are @50 billion dollars. This is too incomplete and far too low a figure for all accidents.

As per the NSC report of 1963, the annual accident toll in USA was estimated at 100500 deaths, 2 x 10" disabling injuries and total economic loss 53 x 10« dollars.

H. M. Vernon estimated the loss in potential production through industrial injuries amounted to 643 x W dollars in 1932.

As per another report, yearly accidents in USA are @ 3 x 10^6 of which industrial accidents at work are believed to be 9 x 10^5 costing 6 x 10^8 dollars and involving 24 x 10^6 man days lost

As per Accident Facts, 1997, NSC, USA, unintentional injury deaths were estimated 93400 in 1996, each year @2.6 million Americans were hospitalised for injuries, @39.6 million were treated in hospital emergency departments and @60.5 million (nearly one in four) required medical attention or suffered at least a day of activity restriction from an injury.

The economic impact of above fatal and nonfatal injuries amounted to $444.1 billion in 1996. This is @ $1700 per capita, or @ $4500 per household.

Such human and economic costs add up to staggering totals, and make it obvious that a major effort to lessen them is in order. Because of the magnitude of this accident problem, all factories should set up safety programmes of various types to deal with the problem.

International Comparison: The industrial (manufacturing) Accident Rates per one million man hours worked in 1990 of some countries are as follows :

Egypt	0.13	Japan	0.01
Tunisia	0.07	Germany	0.07
Poland	0.05	UK	0.02
USA	0.02	New Zealand	0.04
France	0.06	Philippines	0.05
India	0.20		

Thus we have comparatively the highest accident rate.

Inadequacy or Limitations of Data :

It is believed that safety statistics is under reported. Majority of unregistered factories, small factories and industries do not report all cases of accidents, occupational diseases and poisoning, nor do they maintain any record.

See Table 5.2 and footnote under it. Indian Labour Statistics 1991-93, published on 29-5-1995 by Labour Bureau,. Shimla, could accommodate statistics up to 1992 and as mentioned under the foot-note, many States (more than ten) did not send information of industrial injuries for the years from 1984 to 1991. In Table 9.2 on Maternity Benefit paid under the M. B. Act, 1961, it is revealed that 20 States (out of 24) did not send complete information for the years from 1988 to 1992. Gujarat had sent information for one year (1989) only and that too incomplete! This is the situation in many statistical tables. This indicates limitation or inadequacy of data. The main reasons are well-known and as under

1. Lacs of small and medium scale industries are' out of coverage to fill 'returns' for safety information.

2. Lacs of factories may be unregistered due to whatsoever reasons. The result is that, no information is available from them on the matters of **safety, health, welfare** and environment .

3. Thousands of registered factories do not send prescribed 'returns' or necessary statistical information.

4. As the States do not get information from industries, they are unable to send it to the Labour Bureau, Shimla.

5. Even in information available or sent, many are incomplete or do not tally with others.

6. Compilation at every stage takes too much time (years) and causes great delay.

7. Compilation at National level and publication needs further time and results in. delay. Interest and efforts at all levels are necessary to solve this problem.

8. Information on cost of accident is rarely available. A few big factories may be keeping the records of direct and indirect costs of accidents.

9. The cost of loss to the families and society is hardly available.

10. All industries are not covered under the ESI Act and the figures of compensation under this Act and the Workmen's Compensation Act do not give an all-India picture.

11. No record of private medical expenses is traceable from one source.

12. No record of accident expenditures in agriculture, at homes, at shops, stores, roads, godowns and other workplaces is available.

This suggests some forms to be prescribed for such records at such places. Only then we can have the real and full picture of all accidents in the country. How to make this possible is another problem to be tackled by national institutions.

Costing or valuation of material damage or losses is possible, but, how do we value a human life? Can any meaningful price (cost) be assigned to it? How can anyone equate the value of 2500 lives (of Bhopal accident) in terms of cash equivalent ? And how to value the after-effects on impaired parts of the bodies? or after-effects of emotional pains to families? This is all very difficult and therefore, only estimation is possible. This is again an inadequacy or limitations of safety data.

It is interesting to note that Melinek S. J. suggested a method of evaluating human life for economic purposes and he concluded in 1972 the value of human life was about 50000 pounds (this can become many times more at present). He added that there is a large difference between the value people place on their own lives and the value placed on them by society at large, which is usually much lower.

3. ACCIDENT COST TO THE INJURED PERSON AND HIS FAMILY .

Accidents are costly to the injured person, to his family, to the management and to the society. Let us see how much an injured worker would lose due to an accident to him.

In addition to pain, suffering, worries, incapacity, wage .loss, medical and other expenses, he also suffers as under.

If a worker is not covered by any insurance scheme, he has to bear the loss of wages and the cost of medical expenses, transport, fruits, food etc. If he suffers permanent disablement, he loses his earning capacity for life.

If a worker is insured under any scheme, he gets some compensation, medical expenses and some daily allowance which are hardly adequate. No costing is possible for his suffering, pain, worry and incapacitation. Even after return to duty, he is unable to perform his normal work for many days and therefore may lose incentive and overtime wages during that period. Another loss is his mental setback and inability to social functions and recreation.

Example :

Let us take an example of a worker who meets with an accident at his age of 20 years and loses his total earning capacity. His monthly wage is Rs. 1500/-.

As per Workmen's Compensation Act, he will get (60% of 1500) x the relevant factor
= 900 x 224 = 201600, or Rs. 90000/- whichever is more, thus he will get the compensation of Rs. 201600/-.

If the accident would not have happened, he would have worked for another 40 years and would have earned as follows :

1500 p.m. wage x 12 months x 40 years

= 720000.

Considering yearly increment of Rs. 50 throughout the span of 40 years, i.e. increasing Rs. 50 x 12 = 600 each year for 40 years (wage ceiling is not considered because of the periodical wage rise), further earning

= (600 x 1) + (600 x 2) + (600 x 3)+.... (600 x 40)
= 600 (1+2+3+......+40) = 600 x 820 =492000

Therefore total earning = 720000 + 492000
= 1212000.

Thus against Rs. 1212000 he gets only Rs. 201600 which seems much less.

Suppose, he would have died, his family gets (50% of 1500) x the relevant factor = 750 x 224 = 168000, or Rs. 80,000 whichever is more, i.e. Rs. 168000 a still less amount than the compensation for permanent total disablement.

4. ACCIDENT COST TO THE MANAGEMENT

Management suffers two types of costs

1. Direct or Insured or Tangible Costs and
2. Indirect or Uninsured or Intangible (hidden Costs. -

4.1 Direct Costs:

This includes the compensation paid to the injured person, or insurance premium, medical and hospital charges, transport charges directly paid by the employer.

Direct costs are easy to calculate as their money value is directly available. Workers' legal compensation or accident insurance premiums (net premiums after deducting refund if any), medical expenses of doctors' bills, medicine bills, hospital/ dispensary charges etc., extra compensation paid to the injured worker or his family and all other direct expenses/expenditures paid, by the employer due to the accident, constitute direct costs.

If hospital charges' doctor's bill, medicine bill or other expenditure is paid by insurance company, only premium cost should be considered. Direct cost includes insured expenditure and direct payment only.

4.2 Indirect Costs :

Indirect costs are of many types and need careful consideration to determine their 'equivalent money value'. Use of cost data sheets and other methods have been developed to calculate indirect costs. They include following

1. Cost of wages paid for working time lost by insured workers, other than workers' compensation payments.

2. Cost of wages paid for working time lost by workers, other than the injured worker(s).

3. The net cost to repair, or replace material or equipment that was damaged in accident.

4. Extra cost due to overtime work necessitated by accident.

5. Cost of wages paid to supervisors for their time required for activities necessitated by accident.

6. Wage cost due to decreased output of injured worker after return to work.

7. Cost of learning period and preparation of new worker(s).

8. Uninsured medical cost borne by the company.

9. Cost of time spent by higher officers, outsiders and clerical workers on investigations or in restarting the production or in processing compensation application, procedure and other administration.

10. Cost of work interruption due to idle machine, work stoppage or spoilage.

11. Cost of property (including material and equipment) damage due to accident.

12. Uninsured other costs and the miscellaneous unusual costs.

The ratio 4 to 1 : In 1927, **H. W. Heinrich** presented a paper at the National Safety Congress (USA), and placed the indirect cost as an average 4 times the direct cost. This was the origin of much discussed and controversial 4 to I ratio.

Some studies yielded ratios ranging from 8 to I to I to I, but, in general, they supported Heinrich's findings.

Heinrich writes, 'It is not contended that the 4 to I proportion holds true for every industrial accident or every individual plant, and it is granted that in nation wide application the ratio may vary, yet it has already tested sufficiently to provide approximate confirmation'.

After Heinrich's research of 4 to I ratio in 1926, much discussion was carried out. Frank E Bird, Jr., accepted the iceberg principle of hidden costs, dividing them into two categories: uninsured costs of property damage which can be easily quantified and uninsured miscellaneous costs which are difficult to quantify. His estimates of each are higher than original 4 to 1 estimate as shown in Fig. 5.2

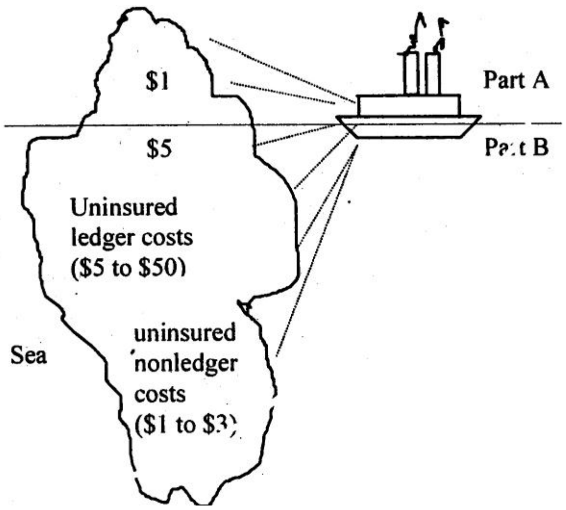

Fig. 5.2 : Bird's Iceberg concept

Part A : Insured costs

1. Medical 2. Compensation

Part- B : Uninsured costs

1. Building damage
2. Tool & equipment damage
3. Product & material damage
4. Production delays & interruptions
5. Many items such as hiring & training, investigation time etc.

Simonds and Grimaldi use the terms 'insured' and 'uninsured' for Heinrich's terms 'direct' and 'indirect' and state that (1) Heinrich's ratio '4 to I' is higher because some of the uninsured (indirect) costs included by Heinrich are not valid and (2) There is no direct correlation between insured (direct) and uninsured (indirect) costs and applying a single ratio gives inaccurate results. They give the following formula –

Total cost =	Insurance cost (i.e. direct cost)	
	+ A x No. of	lost time cases
	+ B x No. of	doctor's cases (no lost time)
	+ C x No. of	Only first-aid cases
	+D x No. of	accidents causing no injuries but causing property damage in excess of specified amounts,

where A, B, C, D are the average uninsured (indirect) costs for each category of cases, and the number of cases refers to the actual count of each type during the period under consideration.

Bird and Germain, however consider this revised concept, an ineffective tool in safety motivation and they suggested, a ledger-costs concept that appear on department ledgers. The main factors considered in accident cost-accounting are -

1. Workers:
   (a) Total cost of workers' compensation benefits.
   (b) Wages and medical costs paid during disability in addition to (a) above.
   (c) Cost of time lost on day of accident and on subsequent days.
   (d) Cost of time spent on light work or reduced output.

2. Machinery, Material, Equipment :
   (a) Cost of repairing damage or cost of replacement.
   (b) Cost of lost production time,

Despite their differences, Heinrich, Simonds and Grimaldi, and Bird and Germain all agree that accident costs tend to be underestimated.

By formula or ledger, total cost calculation does not explain difference between direct and indirect costs, or their ratio, as they are explained by Heinrich's concept (breakup) and ratio.

Factors of Indirect (Hidden) Accident Cost:

The list given by Heinrich is as under :

1. Cost of time lost by injured employee.
2. Cost of time lost by other employees who stop work.
   a. Out of curiosity.
   b. Out of sympathy.
   c. To assist injured employee.
   d. For other reasons.

3. Cost of time lost by foremen, supervisors or other executives as follows:
   a. Assisting injured employee.
   b. Investigating the cause of the accident.

   c. Arranging for the injured employee's production to be continued by some other employee.
   d. Selecting, training, or breaking in a new employee to replace the injured employee.
   e. Preparing statutory accident reports, or attending hearings before Govt. officials.

4. Cost of time spent on the case by first-aid attendant and hospital department staff, when not paid for by the insurance carrier.

5. Cost due to damage to the machine, tools, or. other property or to the spoilage of material.

6. Incidental cost due to interference with production, failure to fulfill orders in time, loss of bonuses, payment of forfeits and other similar causes.

7. Cost to employer under employee welfare and benefit systems.

8. Cost to employer in continuing the wages of the injured employee in full, after his return - even though the services of the employee (who is not yet fully recovered) may for a time l)e worth only about half of their normal value.

9. Cost due to the loss of profit on the injured employee's productivity and on idle machines.

10. Cost that occurs in consequence of the excitement or weakened morale due to the accident. (Stoppage or slawing down of work)

11. Overhead cost per injured employee - the expense of light, heat, rent, and other such items, which continues while the injured employee is a non-producer.

This list is not exhaustive and many points can be added to it, though it is sufficient to point out unexpected loss producing events that follow the consequence of accident.

Ratio Relationship : The following table shows the ratio relationship between these costs in some countries.

Country	Year	Direct Cost	Indirect Cost
UK	1967	1	6.7
USA	1932	1	8
Germany	1954	1	10.7
Austria	1965	1	6.4

In India, such record is not available, but it can be roughly estimated to be 1:3 to 1:8.

Example :

Let us consider an example of a worker drawing Rs. 900/- p.m. and meeting with an accident at his age of 40 (completed) and losing three fingers of one hand (i.e. 30% permanent partial disablement).

Direct Cost (Rs.)

1.	Compensation under Workmen's Compensation Act. From Sr. No. 8 of Part II of Schedule I, 30% of (60% of 900 x the age factor) = 0.30 (540 x 184.17) = 0.30 x 99451.8	=	29835
2.	Medical & Hospital charges including fees, medicines, milk, fruits etc.	=	02137
3.	Transportation charges	=	00200
	Total direct cost Rs.		32172

Indirect Cost (Rs.)

1.	Cost of lost time -		
	A.	By injured worker	1870
	B.	By other workers	5330
	C.	By Supervisors & executives	6240
	D.	By first-aid staff and Clerical expense	1260
2.	Cost of production loss due to -		
	A.	Idle m/c and clean up etc.	1390
	B.	Damage to the machine	7310
	C.	Damage to tools	5650
	D.	Damage to materials	4620
	E.	Spoilage of materials	2550
3.	Incidental cost due to -		
	A.	Fulfilling order (supply) in time (worked overtime)	6280
	B.	Payment of forfeits	
	C.	Welfare & benefit system	0840
	D.	Less production by the injured worker after his return to work	8560
	E.	Loss of profit & productivity	5356
	F.	Production loss by weakened morale of others	2644
4.	Overhead & Administrative expense		4800

Total indirect (uninsured) Cost	64700
Total cost of the Accident 32172 + 64700 =	96872

Here the ratio comes to @ 1:2, but, this is widely variable depending upon each case.

Suppose due to a fatal accident 3500 workers do not work for one shift or day, that estimate only would cost Rs. 3500 x 60 (daily wage) = 210000 and adding to the indirect cost, the ratio would be 1:8.

Suppose direct cost is not born by the company which paid accident insurance amount for that-worker as Rs. 16000, then ratio will become 16200/64700=l:4. See also Part 4 for costs discussion.

See Part 5 & 7 of Chapter-29 for legal provisions.

5. UTILITY AND LIMITATION OF COST DATA

Data of accident costs are many difficult to get and they have limitation also. But they are most useful to convince tile management to plan and work for safety.

5.1 Utility (Usefulness) of Cost Data to Convience Management:

Direct cost of accident is directly available and is very much useful to calculate expenditure and budgetary estimate on -predictable accidents or fire / explosion and other risks.

Indirect costs are also real costs and they should be calculated to quantify or demonstrate in meaningful way. Such unproven costs may seem unreal to the management and it may not be convinced. However Safety Officer should try to quantify these hidden costs, to explain the iceburg concept (Fig. 5.1) to the management and to draw a conclusion that 'preventive costs may be less than the total costs of accidents' - a powerful stimulus for the management to invest for accident prevention' work.

Each industry should try to calculate accident costs of all the accidents happened in last (completed) year and to compare the ratio year to year. This will indicate where and how we can reduce the accident costs. The best effort was made by Godrej and Boyce Mfg. Co. Ltd., Mumbai by preparing an impressive book on such accident costs studies and also showing by an exhibition.

There is a great significance of this ratio of costs to statisticians, employers, employees, safety officers and insurance salesmen. It supplies powerful stimulus to convince management for preventive action. It emphasises that - ,

1. Cost estimates may remain underestimated and the million - rupees may be increased 4 to 5 times.
2. The employers must worry about accident cost and accept accident prevention as their economic activity and duty.
3. The work of safety officer has a real monetary value and
4. It enhances the value of the service of an insurance salesman.

5.2 Limitation of Costs Data:

Limitation (inadequacy) of accident data is discussed in Part-2. Direct (insured) and indirect (uninsured) costs of various types are discussed in Part-4. From this discussion it is inferred that the data of direct cost is easily available as insurance premiums or direct compensation costs or other medical and safety expenditure from records.

It is the indirect (uninsured) and other intangible costs which are not directly available and are to be calculated from other data. Such points mentioned in Part- 4 show the limitation of cost of data.

Except a very few companies, hardly data is available on cost of time spent by the injured worker due to accident, time spent by co-workers, supervisors and others in inquiring or investigating that accident, time spent by idle machine or interruption or production loss, money value of repair or replacement, money value of delay in fulfilling orders, money value in preparing a substitute, cost of damage to public or public liability claims, loss of profit due to cancelled contracts or orders or rejects, cost of excess spoilage by new employees and demurrage etc. Cost of damage to environment and cost of court penalties due to accident cases are also unpredictable. This indicates the limitation of cost data.

6. ACCIDENT SOCIETY COSTS TO THE

The society suffers losses in three ways :

1. The family - a part of the nearest society suffers pain, financial hardship and service or maintenance loss by the injured person or his death.
2. The society 'as consumers pay the increased cost of production due to direct and indirect cost to the management.
3. The society bears the social and financial burden of maintenance of all injured persons and their families. Thus knowingly or unknowingly every member of the society bears a proportion of the costs of accidents, and
4. The society losses service or help by that person.

Therefore employee, employers and society all have to work collectively for accident prevention.

7. COST COMPILATION PROCEDURE

Following examples illustrate the cost compilation procedure.

Example :

A worker dies in an accident at his age of 55 when he was drawing Rs. 6600/- p.m. He was very experienced worker and leader of the factory of 3650 workers. If he would have not died, he would have worked another 5 years. Calculate the cost of this accident to his family, his management, the society and the overall cost totalling all the three factors.

(1) Cost to the family :

As per the Workmen's Compensation Act, Section 4(1) (a) and Explanation, his family will get 50% of 2000 x the relevant factor = 0.50 x 2000 x 135.56 = Rs. 135560.

If he would have not died and worked for further five years, he would have earned 6600: x 12 x 5 = Rs. 396000. Considering yearly increment of Rs. 50 throughout the span of 5 years, increasing Rs. 50 x 12 == 600 each year for 5 years, he would have further earned

= (600 x 1) + (600 x 2) + ... + (600 x 5)
= 600 (1+2+3+4+5) = 600 x 15 = 9,000.

Therefore his total earning would have been Rs. 396000 + 9000 = 405000.

Deducting the compensation received, cost (monetary) of accident to his family

= 405000 - 135560 = Rs. 269440 ....(1)

The cost of the person lost is intangible.

(2) **Cost to the Management (Estimates) :**

		Rs.
(A)	**Direct Cost**	
1.	Compensation under W. C. Act	135560
2.	Medical & Hospital Charges	000750
3.	Transportation Charges	000690
	Total Direct Cost	137000
(B)	**Indirect Cost**	
1.	Cost of time lost by	
	a. Injured worker (including extra payments)	----
	b. Other workers	012744
	c. Supervisors & executives	016423
	d. First-aid staff and clerical expense	001077
2.	Cost of production loss due to	
	a. Idle m/c and clean up etc.	008375
	b. Damage to the machine	002125
	c. Damage to tools/equipment	000412
	d. Damage to materials	001188
	e. Spoilage of materials	000200
3.	Incidental cost due to	
	a. Fulfilling order in time (required overtime)	001682
	b. Payment of forfeits	---
	c. Welfare & benefit system	002318
	d. Loss due to preparing substitute	008256
	e. Loss of profit & productivity	011944
	f. Loss of production by weakened morale of others	033689
	g. Wage& production loss by half day work-stoppage by all workers' 0.5 x 60 x 3650=	109500
4.	Overhead and Administrative	020311
	Total indirect cost	230244

The ratio D. C. : 1. C. = 137 : 230 = 1: 1.7

If the direct cost is insured by some insurance agency and if we consider the annual insurance premium as Rs. 40000, the direct cost would be Rs. 40000 and the ratio, then will be 40:230 = 1:6.

The total cost to the management = 137000 + 230244 == 367244, if uninsured, and 40000+230244=270244, if insured .....(2)

Thus, insurance saves cost of accident.

(3) Cost to the Society (Estimated) :

(A)	Loss to his family, other than the wage loss (in the form of other services)	55800
(B)	20000 consumers pay the product price rise assuming Rs. 2 each, then	40000
(C)	Social and financial help by the society	04200
	Cost to the society	Rs. 100000

… (3)

Therefore the overall (national) cost totaling above three factors

= (1)+(2)+(3) = 269440 + 367244 + 100000 -Rs. 736684

Thus one fatal accident costs to the nation in lakhs of rupees.

Estimating minimum cost of fatal accident as Rs. 1 lakh and @ 1800 fatal accidents in factories in India per year, the minimum total cost of all these accidents would be 1800 lakhs rupees, and estimating @ 120000 total fatalities (of all kind), their total national cost would be Rs. 120000 x 100000 = 12×10^9. What a great target (and cause) for all safety people to minimise this national annual loss !

8. CRAIG SINCLAIR'S STUDY OF ACCIDENT COST, PREVENTIVE COST AND THEIR RELATIONSHIP

T. Craig Sinclair on behalf of the Robens Committee on Health and Safety carried out a detailed study and published a paper 'A cost effectiveness approach to individual safety, HMSO London, (1972)'. A brief summary of his concept is given below :

*

Estimate of Accident Costs :

The costs of accidental injuries are made up of three parts - fatalities, serious injuries (over 4 weeks off work) and other injuries. Thus we can write.

AC = RD (ASd + AOd) +RS (ASs + AOs) + RO (ASo + AOo) Where

AC = annual Accident Cost per worker
RD = annual Risk of Death per worker
RS = annual Risk of Serious injury per worker
RO = annual Risk of Other injury per worker
AS = Subjective element of cost and
AO = Objective element of cost with second subscript d, s or o for death, serious injury and other injury.

Sinclair has applied this method with meaningful results to large groups of workers in entire industries including agriculture. The method is not useful for very small groups where the resuite will have little statistical significance.

9. FORMS OF ACCIDENT STATISTICS

Three forms for useful accident statistics are suggested as under:

9.1 Accident Report Form:

An internal accident report form should be devised to contain facts as under:

1. Statutory information (say. Form No. 21, 21-A and 22 under the Gujarat Factories Rules).
   a) Name, Address, Phone arid Fax No. of the Factory.
   b) Name, Address, Phone and Fax No. of the Occupier. .
   c) Name, Age, Sex and Address of the Injured or Died Person.
   d) Experience, training, qualification etc.
   e) Place, Date, Time, Shift and Type (Fatal, Nonfatal, Serious etc.) of the Accident or Dangerous Occurrence.
   f) Nature, Type, Extent and Body part of Injury, Poisoning or Disease.
   g) The severity of injury in details, Short mention like fatal, non-fatal, abrasion, etc., are insufficient.
   h) Doctor and Medical Staff who attended the Victim.

2. All causes - immediate and contributing - of accident. Possible detail should be given.

3. Nature of job and exact work being done by the injured worker at the time of accident.

4. Psychological data with previous accident history, if any.

5. Physiological factors and bodily defects or habits, if any.

6. Physical conditions - work load, physical, mechanical, chemical and environmental factors present at that time.

7. Names, Addresses and Statements of co-workers and witnesses who saw the accident.

8. Proofs, evidences, photographs, records, register etc. to understand the cause(s) of the accident.

9. Remedial measures
   a) Immediately required to prevent the recurrence.
   b) Required as second phase of compliance.

10. Any other relevant information pertaining to above accident.

Name and Signature of Supervisor __________
Safety manager______
Plant incharge _______

Then from this internal accident report, required statutory form should be filled in.

9.2 Accident Investigation Form:

A specimen form is devised and given below to keep a good record, of accident statistics. It is useful for costing and classification of individual accident to conclude sharply for its prevention. Information is to be given by the Dept. concerned and to be maintained for internal safety audit.

Name & Address of the Factory or Industry :
Type of Manufacturing Process :
Industrial Classification :
Total workers _________ Shifts _________ H.P. _________

(A) Supervisor's Report

1. Injured person's (a) Name & Address ______________________________
   (b) Employee Code No. ________ (c) Department _________ .
   (d) Age (years completed) _______ (e) Sex _____ .
   (f) Occupation/Designation __________________________________

2. Date & Time of the Accident _________________________________

3. Place and Department of Accident ____

4. When did the injured person start his work in this place?

5. Causation Analysis :
   (a) Caused by machinery? (Yes/No) _________
   Give name of the machine, H.P., its part causing the accident, whether it was moved by power, description of the process/operation going on and what the injured person was exactly doing at that time.
   (b) If caused by another person's fault, give its details.
   (c) Names and addresses of co-workers and witnesses who actually saw the accident or knew about it.
   (d) Nature and type of accident.
   Nature : Fatal? ______ Statutorily Reportable? ________ Causing Injury? (i.e. disabling or lost-time) ______ Causing no injury but property damage only? _____ Other type _______
   (e) Nature, extent and description of injury.
   (f) Supervisor's exact opinion about the direct and indirect cause, whether it was due to unsafe condition or action or their combination and actual reasons with facts.

(B) Medical Department's Report :

1. Description of injury in details (Nature & Extent).
2. Description of permanent health effect if any.
3. Description of the First-Aid (including antidote) given.
4. Description of after treatment.
5. Date of found fit to resume duty (Mention subsequently)
6. Name of Doctors /Medical Staff who gave the treatment.
7. Cost of total medical expenses.
8. Cost of extra hours worked by the doctor and his staff due to this accident.

(C) HR/ Personnel Department's Report:

1. Injured person's (a) Date of Joining ______ (b) Date of Birth _____ (c) Qualification __________
   (d) changes of Departments ________ (e) Training & Experience (f) Monthly wage Rs. _______
   (g) Hourly wage Rs. _______ (h) Name & Address of near relative to be informed immediately

2. Date of resuming duty _________. and Man-days lost _______
3. Amount of accident insurance premium for the worker _______
4. Amount of Compensation paid/payable ______ and by whom _________.
5. Other amount (eg. extra componsation) paid to the injured person or/and his family

(D) Safety Department's Report:

1. Date of investigation started _______ by whom ______________________
2. Names and Designation of investigating officer(s) _____________________
3. Date of investigation completed _____________
4. Concluded causes of the accident (Give details) :
   (a) Unsafe condition (main) ?
   (b) Unsafe action (main) ?
   (c) Their combination or multiple causes ?
   (d) Psychological factors ?
   (e) Physiological factors ?
   (f) Environmental factors ?
   (g) Physical conditions or work load ?
   (h) Description of the cause(s).
5. Classification of the Accident.
6. Remedial Safety Measures.
   (a) List of total measures suggested in order of priority.
   (b) List of measures already complied with. ,
   (c) List of measures yet to be complied, within what time and by whom

Date :

Signature of the
Manager or Occupier

9.3 Accident Costs Form

1. Name & Address of the Factory/Industry ____
2. Name & Address of the injured person _________________________Employee/Code No ______
3. Type of injury _________ (Death, permanent total disablement, permanent partial disablement, temporary disablement)
4. Nature of injury (body effect) _____________
5. Date & Time of Accident _______________ Place of Accident _______
6. Department ___________ Process/operation ___________
7. Hourly wage of the injured person _______
   Hourly wage of the supervisor ______
   Hourly wage of the workers and other officers who left their work and spent their time for the accident (i) (ii) (iii) (iv) (v)
8. Direct Cost Computation. Rs.
   (a) Amount directly paid by the company as Compensation or any premium or contribution under the W. C. Act or ESI Act or any Insurance Scheme for the Worker _______
   (b) Medical and Hospital Charges _______
   (c) Transportation Charges for Medical treatment _______
   (d) Extra Compensation or Help to the injured worker or his family members including payment of wages given during the period of absence due to the accident and not adjusted' against the amount of compensation, including any amount paid in whatsoever name _______

   Total Direct Cost (DC) Rs. _______

9. Indirect Cost Computation.

Time (hours) spent by the injured person and others as in 7 above.

(i) (ii) (iii) (iv) (v)

			Rs.
(1)	Therefore cost of time lost by		
	(a)	Injured worker	__
	(b)	Other workers	__
	(c)	Supervisors, Officers and Executives	__
	(d)	First-aid and clerical staff	__
	(e)	Outside agency (viz. Safety Consultant)	__
	(f)	Other persons	__
(2)	Cost of material and production loss due to		
	(a)	Spoilage of materials	__
	(b)	Damage to materials	__
	(c)	Damage to machine/vessels	__
	(d)	Damage to tools/equipment	__
	(e)	Idle m/c and clean up, repair etc.	__
	(f)	Other damage and repairs	__
(3)	Incidental cost due to		
	(a)	Extra work for fulfilling the order in time (required overtime payment)	__
	(b)	Payment of forfeits	__
	(c)	Welfare and benefit system	__
	(d)	Preparing or hiring substitute	__
	(e)	Decreased output (production) by the injured and others for some time	__
	(f)	Wages and production loss due to mass work-stoppage by workers	__
	(g)	Overhead and Administrative expense	__
	(h)	Loss of profit and productivity	__
	(i)	Amount not classified elsewhere	__
		Total Indirect Cost (IC) Rs.	__

10. The Ratio of IC to DC (Total of item 9/Total of item 8) __
11. Cost of accident to the management = Total of item 8+Total of item 9 __
12. Cost of accident to injured person's family __
13. Total cost of accident = 11+12 __
14. Estimate of Preventive costs __

Signature of Occupier / Manager.

In our country such accident and cost forms are not maintained by industries in respect of all accidents. In want of them, exact causation, preventive measures B - cost of accident cannot be determined in details. Therefore such forms (or modified as per own requirement) should be voluntarily maintained by all industries for the purpose of precise safety statistics. This will highlight the importance of budget for preventive efforts.

10. MEASUREMENTS OF SAFETY PERFORMANCE

10.1 Terminology:

IS:3786 defines as under :

Accident An unintended occurrence arising out of and in the course of employment of a person resulting in an injury.

Death: Fatality resulting from an accident

Disability Injury (Lost Time Injury) : An injury causing disablement extending beyond the day of shift on which the accident occurred.

Non-disabling Injury: An injury which requires medical treatment only, without causing any disablement whether of temporary or permanent nature.

Reportable Disabling Injury (Reportable Lost Time Injury) : An injury causing death or disablement to an extent as prescribed by the relevant statute (viz. the Factories Act and the ESI Act).

Days of Disablement (Lost Time): In case of disablement of a temporary nature, the number of days on which the injured person was partially disabled as defined below. In case of death or disablement of a permanent nature whether it be partial or total disablement as defined below, man-days lost means the charges in days of earning capacity lost due to such permanent disability or death as specified in Appendix B. In other cases the day on which the injury occurred or the day the injured person returned to work are not to be included as man-days lost, but all intervening calendar days (including Sundays, days off, days of plant shut down etc.) are to be included. If after resumption of work, the person injured is again disabled for any period arising out of the injury which caused his earlier disablement, the period of such subsequent disablement is also to be included in the man-days lost.

Partial Disablement: This is of two types; (i) disablement of a temporary nature which reduces the earning capacity of an employed person in any employment in which he was engaged at the time of the accident resulting in the disablement and (ii) disablement of a permanent nature which reduces his earning capacity in every employment which he was capable of undertaking at the time.

Total Disablement: Disablement, whether of a temporary or permanent nature, which incapacitates a workman for all work which he was capable of performing at the time of the accident resulting in such disablement, provided that permanent total disablement shall be deemed to result from every type of injury specified in Part A of Appendix A or from any combination of injuries specified in Part B of Appendix A where the aggregate percentage of the loss of earning capacity, as specified in that part against those injuries, amounts to one hundred percent.

Man-hours Worked: The total number of employee-hours worked by all employees working in the industrial premises. It includes managerial, supervisory, professional, technical, clerical and other workers including contractors' labour.

Man-hours worked shall be calculated from the pay roll or time clock record including overtime. When this is not feasible, the same shall be estimated by multiplying the total man-days worked for the period covered by the number of hours worked per day. The total number of man-days for a period is die sum of the number of persons at work on each day of the period. If the daily hours vary from department to department, separate estimates shall be made for each department and the result added together. When actual man-hours are not used, the basis on which the estimates are made shall be indicated.

Scheduled or Time Charge: For charges or equivalent man-days lost for death or total disablement see Part-A and for partial disablement see Part-B of Appendix-A of IS: 3786.

For death or total (100%) disablement, equivalent man-days lost are specified as 6000.

The Workmen's Compensation Act, 1923 also defines following terms:

Partial disablement of temporary nature or permanent nature, Total disablement (temporary or permanent), Wages and Workmen.

Section 4 and Schedule I & IV are important for calculating the amount of compensation. A concept of relevant (age) factor was added with effect from 1-7-1984. Section 4 was amended with effect from 15-9-1995 raising the limits of compensation.

The Employees State Insurance Act should also be referred where it is applicable. It also contains the similar terms and schedules.

See Part 7 of Chapter-29 and Part 6 of Chapter - 4 for further information.

10.2 Safety Performance Rates :

There are many types of safety performance rate as under:

10.2.1 Frequency Rate:

A question 'How often do injuries occur?' is replied by the frequency rate which is defined as the disabling (lost time) injuries per 106 man-hours worked.

$$F_1 = \frac{\text{No. of lost time injury} \times 10^6}{\text{Manhours worked}}$$

$$F_R = \frac{\text{No. of lost time injury} \times 10^6}{\text{Manhours worked}}$$

If the injury does not cause loss of time in the period in which it occurs but in a subsequent period the injury should be included in the frequency rate of the period in which the loss of time begins.

If an injury causes intermittent loss of time, it should only be included in the frequency rate once that is, when the first loss of time occurs.

Since frequency rate F, is based on the lost time injuries reportable to the statutory authorities, it ma) be used for official purposes only. In all other cases frequency rate F, should be used for comparison purposes.

In some country, the frequency coefficient (F) h determined by

$$F = \frac{\text{No. of injuries for a given period} \times 1000}{\text{Total Man – hours of exposure}}$$

10.2.2 Fatal Accident Frequency Rate(FAFR):

It indicates fatalities per 108 man-hours worked. It is the number of deaths from industrial injuries expected in a group of IOQO people during their working lives (1000 x 40 years x 52 weeks x 48 hours = 1000 x 40 x50x 50 = 10^8)

FAFR of chemical Industry			FAFR in UK Of		
France	-	8.5	Chemical Ind.	-	4
West Germany	-	5	Steel Ind.	-	8
UK	-	4	Coal Mining	-	40
USA	-	5	Air Crew	-	250
FAFR for non-industrial activities					
Staying at home	-	3			
Travelling by bus	-	3			
Travelling by car	-	57			
Traveling by air	-	240			
Motor cycling	-	660			
Rock climbing	-	4000			

10.3 Percentage Reduction in Frequency rate :

$$PRFR = \frac{\text{Frequency rate now} \times 100}{\text{Frequency rate past}}$$

This is used to decide awards. Average PRFR for two consecutive years is considered.

10.2.4 Weighted Frequency Rate:

While giving National Safety Award, this rate : considered and given bv -

$$WFR = \frac{(\text{No. of fatal accidents} \times 10) \times 10^6}{\text{Total man – hours worked}}$$

$$+ \frac{(\text{No. of permanent total dis – abilities} \times 10) \times 10^6}{\text{Total man – hours worked}}$$

$$+ \frac{(\text{No. of Nonfatal Accidents}) \times 10^6}{\text{Total man – hours worked}}$$

Here each fatal accident and permanent total disability are equated with 10 non-fatal accidents.

10.2.5. Safe T-Score :

It is given by

SafeT-Score =

$$\frac{\text{Frequency rate now – Frequency rate past}}{\sqrt{\dfrac{\text{Frequency rate past} \times 10^6}{\text{Manhours worked now.}}}}$$

Positive (+) STS indicates a worsening record while negative (-) STS indicates an improving record over the past.

If STS is **It indicates**

Between +2 & -2	Change is not significant. There may be random fluctuation only.
More than +2	Record is worsening than it was in the past. Something wrong has happened.
Less than – 2	Record is improving than it was in the past. Something better has happened.

Thus Safe-T-Score is useful to compare our safety record with the past and to control it if it is found worsening.

10.2.6. Incidence Rate:

General incidence rate is the ratio of the number of injuries to the number of employees during the period under review. It is expressed as the number of accidents or injuries, per 1000 persons employed.

$$I_L = \frac{\text{No. of lost –time accidents or injuries x 1000}}{\text{Average No. of persons employed}}$$

$$I_R = \frac{\text{No. of reportable lost time accidents or injuries x 1000}}{\text{Average No. of persons employed}}$$

10.2.7 Severity Rate:

A question 'How serious are the injuries? is replied by the severity rate which is defined as the number of days of lost time per 106 man-hours worked.

$$S_L = \frac{\text{Mandays lost due to lost time injury x } 10^6}{\text{Manhours worked.}}$$

$$S_R = \frac{\text{Mandays lost due to reportable lost time injury x } 10^6}{\text{Manhours worked.}}$$

The severity coefficient (S) is determined by

$$S = \frac{\text{Mandays lost in all accidents for a given period}}{\text{No. of injuries for a given period}}$$

Since severity rate S_R is based on the lost time injuries reportable to the statutory authorities, it should be used for official purposes only. In all other cases severity rate S_L should be used for comparison purposes.

Here man-days lost due to temporary total disability and man-days lost according to schedule of charges for death and permanent disabilities are as given in Appendix A (15:3786-1983). In case of multiple injury, the sum of schedule charges shall not be taken to exceed 6000 man-days. In Appendix A, equivalent man-days for death and other total disablement are 6000, and they are gradually decreased with decrease in percentage of loss of earning capacity against named partial disablement.

10.2.8 Mean Duration Rate:

It is an average number of days lost per accident

MDR = $\underline{\text{Total number of mandays lost}}$

$$= \frac{\text{Total number of accidents}}{}$$

$$= \frac{\text{Severity Rate}}{\text{Frequency Rate}}$$

It is also called average days charged or average severity per injury and given by:

$$\text{Average days charged} = \frac{\text{Severity Rate}}{\text{Frequency Rate}}$$

$$\text{Mandays lost per accident} = \frac{\text{Total days lost or charged}}{\text{Total no. of disabling injuries}}$$

10.2.9 Duration Rate :

It is an average number of man-hours worked per accident.

$$DR = \frac{\text{Number of manhours worked}}{\text{Total number of accidents}}$$

10.2.10 Disabling Injury Index:

$$DII = \frac{\text{Frequency Rate x Severity Rate}}{1000}$$

Disabling Index is also given as :

DII = Frequency Rate + 10% of Severity Rate.

This index can be used to compare plant to plant.

10.2.11 Frequency Severity Index or Indicator:

$$FSI = \frac{\text{Frequency rate x Severity rate}}{1000}$$

This is the square root of Disabling Injury Index. It gives combined effect of frequency and severity rate. This index can be used to compare-plant to plant. This can be used to indicate degree of improvement.

10.2.12 Motor Vehicle Accident Rate:

$$MVAR = \frac{\text{Number of accidents x } 10^6}{\text{Miles of operating exposure}}$$

10.2.13 The Cost Factor:

It is the total compensation and medical cost incurred per 1000 workers of exposure.

$$\text{Cost Factor} = \frac{\text{Cost incurred x 1000}}{\text{Total man-hours worked}}$$

Here cost incurred includes the actual compensation and medical costs paid for cases which occurred in a specified period plus an estimate of what is still to be paid for those cases. The 'estimated cost incurred' is an estimate of cost incurred based on averages.

'Cost of property damage' is a measure of damage to property of others caused by company (our) operations.

10.2.14 Cost Severity Rate:

$$\text{Cost Severity Rate} = \frac{\text{Total cost of accidents} \times 10^6}{\text{Total Production Man-hours}}$$

10.2.15 Money Loss Rate:

$$\text{MLR} = \frac{\text{Loss expenditure} \times 10^6}{\text{Manhours worked or Miles of Operating Exposure}}$$

$$\text{Loss Ratio} = \frac{\text{Direct money loss paid out in claims}}{\text{Premium paid to Insurance Company}}$$

10.2.16 Safety activity rate:

It is determined by the following formula :

$$\text{SAR} = \frac{\text{Safety Activity} \times 5 \times 10^6}{\text{Man-hours worked} \times \text{Average No. of employees}}$$

Here 'Safety activity' is the sum (during the unit period) of safety recommendations made, unsafe practices reported, unsafe conditions reported and the number of safety meetings held. Thus a safety activity rate curve can be plotted for any period - a week, month, year etc. and the safety performance can be compared.

10.2.17 Risk of Accident:

It is a product of probability (frequency) of the occurrence of an accidental event of a given kind and of its severity (consequence).

Accident Risk = Total Loss of all accident occurrences

$RAC = (FK \times SC)_A$

Where

FK = Frequency FK i.e. number of accidents A of a

given kind in period of time = A / T

SC = Severity SC i.e. magnitude of consequence C from

accident A of a given kind = C / A

10.2.18 The Rate of Labour Turnover:

It is expressed as T = S/F

Where

T = Rate of Labour Turnover

S = No. of Separations
F = Average labour force for a given period of time.

By multiplying the fraction by 100, the percentage turnover is obtained.

If R = No. of Replacements and U = Unavoidable Separations, the rate is also given as

T = R /F and T = R – U / F

Statistical Period:

Rates for any period, that is month, quarter or year shall include injuries which occurred during the period, together with any injuries which occurred in the previous 12 months and which have not already been included in earlier calculations.

Any injury which occurred in a previous period and which did not cause lost time at the time of occurrence, but caused lost time in the current period, shall be included as a lost time injury in the current period.

10.3 Significance and Drawbacks of Injury Rates:

10.3.1 Significance of Injury Rates :

1. The injury rates are useful to -

   (a) Measure the frequency and seriousness of accidents of a given department, branch or a factory.
   (b) Determine from month to month or year to year whether the condition is getting better or worse.
   (c) Compare the experience of one operating unit with one or more other similar units and
   (d) Serve as a basis for an accident-prevention contest between two or more operating units.

2. A serious accident has a considerable effect on the accident severity rate (due to increased mandays lost) but it does not greatly affect the accident frequency rate.

3. The frequency and severity rates give valuable information on the-safety situation of an industry or its departments within the industry. They are useful in planning the immediate safety measures to control accidents in the industry.

4. Injury rates can be computed for a week, a month, a year or for any period of time by using the same formula. Thus they .form a base of accident statistics for a particular period. The rates are useful in comparing safety records for the same period of two or more plants, even though they are dissimilar in size.

5. Frequency rate can be used to compare present safety performance with the past and the good or bad performance of our own or of others. A high frequency rate indicates need to reduce accidents, but it is unable to give any hint as to what action.

6. Reduction in severity rate indicates a reduction in deaths and other serious injuries. Increase in severity rate, even though the frequency rate is decreased, indicates a definite need for effective Measures to eliminate hazards. Decrease in frequency rate may not necessarily bring decrease in severity rate. Circumstances causing them may be different.

7. Severity is a matter of good or bad luck but it is connected with frequency. Out of ten accidents, there may not be any serious accident, but out of hundred, there may be some serious accidents. Therefore it is said that take care of the frequency rate, then the severity rate will take care of itself. But this is not completely true. Even one or few accidents can result in fatality or seriousness. Therefore, safety measures are more important.

8. Frequency rate can become a basis for comparing two or more units, in a safety contest. Severity rate cannot become a good basis of comparison except when the severity only is to be compared in all units.

9. Where small, minor or first-aid cases are excluded, to keep the safety record good, it is always necessary to give first-aid or necessary treatment to all such cases and to remove the hazards.

   Prompt first-aid and redressing action to injured workers decreases the man-days lost which in turn, decreases the severity rates.

10. Safety engineers/officers can use the injury rates
    (a) To compare their units with the average for the industry.
    (b) Their periodical safety improvement or deterioration.
    (c) To find less hazardous operations.
    (d) To check how well their departments are doing (an increase in rates indicates lack of supervisory control) and
    (e) To determine which department had the best performance etc.

10.3.2 Drawbacks of Injury Rates :

1. No rate is capable of giving complete picture of safety performance. The frequency rate indicates a number of accidents per man-hours worked only. Type, cause, severity, agency or factors of accidents are not represented. The severity rate indicate a ratio of total man-days lost to total man-hours worked only. Type, cause, frequency, agency or factors of accidents are not represented Thus, die injury rates are the partial indicators of injury cases only.

2. Many accidents and property damage or time losses not causing any man-days lost are not properly indicated by frequency or severity rates.

3. Comparing two plants / factories based on their frequency or severity rates is not a good practice. It does not give correct picture as the types of hazard, working conditions/ actions, number and type of manual handling or exposure, attitude of workers, attitude of management etc. differ between them and these factors have definite effects on the frequency and the severity rates.

4. Denominator of both the rates (FR & SR) is 'man-hours worked'. Mostly these figures are selected from 'Attendance Register and there is a difference between 'Attendance in Register' and actually working under hazard. Many supervisors, officers and workers sit in offices or cabins or have idle hours. Even then "such hours' are included in 'man-hours worked'. Thus these rates do not give the absolute correct safety picture.

5. Severity rate indicates only 'absence' due to an accident. It does not represent actual severity of pain and suffering of a worker. Equal severity rates of two factories indicate 'the same status of safety~ therein, while it is a fact that there may be wide difference in types of injuries, their seriousness, pain and suffering. The same 'man-days lost’ are possible by ten normal accidents or by one serious accident and the result (severity rate) will be the same.

6. In frequency, severity and other rates, multiplication by 106 gives high figures. Labour Bureau, Shimla, uses W. See Table 5.2 and 5.9.

These are some drawbacks of injury rates.

10.4 Worked Examples :

1. Calculate different injury rates for. a factory employing average 50 workers for the year during which 100 lost-time (disabling) injuries (accidents) took place and totally 500 man-days lost. The workers worked 48 hours a week and S2 weeks in the year. If total cost of the above 100 accidents is Rs. 70,500 calculate the cost severity rate.

$$\text{Frequency rate} = \frac{\text{Injury} \times 10^6}{\text{Man-hours worked}}$$

$$= \frac{100 \times 10^6}{50 \times 48 \times 52} = 801.28$$

$$\text{Severity rate} = \frac{\text{Mandays lost} \times 10^6}{\text{Man-hours worked}}$$

$$= \frac{500 \times 10^6}{50 \times 48 \times 52} = 4006.41$$

$$\text{Incidence rate} = \frac{\text{Injuries} \times 1000 \quad 0}{\text{Average workers employed}}$$

$$= \frac{100 \times 1000}{50} = 2000$$

$$\text{Disabling Index} = \frac{\text{Frequency rate} \times \text{Severity rate}}{1000}$$

$$= \frac{801.28 \times 4006.41}{1000} = 3210.256$$

$$\text{Average days charged} = \frac{\text{Sev. Rate}}{\text{Freq. rate}} = \frac{4006.51}{801.28} = 5$$

$$\text{Or} = \frac{\text{Mandays lost}}{\text{Freq. rate}} = \frac{500}{100} = 5$$

$$\text{Frequency Coefficient} = \frac{\text{Injuries} \times 1000}{\text{Man- hours worked}}$$

$$\text{Severity Coefficient} = \frac{\text{Mandays lost}}{\text{Injuries}} = \frac{500}{100} = 5$$

$$\text{Cost Severity rate} = \frac{\text{Total cost of accidentx } 10^6}{\text{Man-hours worked}}$$

$$= \frac{70500 \times 10^6}{50 \times 48 \times 52} = 564903.84$$

2. If in the factory of Example (1) above, there were 150 safety recommendations, 390 unsafe practices reported, 50 unsafe conditions reported and 10 safety meetings and programmes arranged during the year, calculate the safety activity rate.

$$\text{Safety Activity Rate} = \frac{\text{Total Safe Activity} \times 5 \times 10^6}{\text{Man – hours worked} \times \text{Av. Workers employed}}$$

$$= \frac{(150 + 390 + 50 + 10) \times 5 \times 10^6}{50 \times 48 \times 52 \times 50} = 480.76$$

3. In a factory the average daily rate of employment per shift is 1500.' There are 3 shifts of 8 hours. In a year, the factory works for 300 days. If the total reportable accidents in the year was 80 and man-days lost were 200, find the frequency and severity rates of accidents, and the Frequency Severity Indicator.

$$F = \frac{80 \times 10^6}{1500 \times 8 \times 3 \times 300} = 7.40$$

$$S = \frac{2000 \times 10^6}{1500 \times 8 \times 3 \times 300} = 18.51$$

$$FSI = \frac{F \times S}{1000} = \frac{7.40 \times 18.51}{1000} = 0.1369$$

4. Firm A has 60 workers working 48 hours a week and 20 accidents (lost time) resulting in 120 man-days lost. Firm B has 80 workers working 48 hours a week and 30 accidents resulting in 150 man-days lost. Which firm has the better safety performance during the same six months?

Six months = 52 / 2 = 26 weeks

$$FA = \frac{\text{Injuries} \times 10^6}{\text{Manhours worked}} = \frac{20 \times 10^6}{60 \times 48 \times 26} = 0267.09$$

$$FB = \frac{\text{Injuries} \times 10^6}{\text{Manhours worked}} = \frac{30 \times 10^6}{80 \times 48 \times 26} = 0300.48$$

$$S_A = \frac{\text{Mandays lost} \times 10^6}{\text{Manhours worked}} = \frac{30 \times 10^6}{80 \times 48 \times 26} = 0300.48$$

$$S_A = \frac{\text{Mandays lost} \times 10^6}{\text{Manhours worked}} = \frac{150 \times 10^6}{80 \times 48 \times 26} = 1502.40$$

Comparing frequency rates, firm A has less rate, therefore better safety performance from frequency point of view. Comparing severity rates, firm B has less rate, therefore better safety performance from severity point of view.

5. Given below are accident statistics of Factories A & B :

Factory	Manhours worked	Non fatal Accidents	Fatal Accidents	Man days Loss
A Regular workers Contract workers	 1200000 250000	 10 2	 - -	 400 100
B Regular workers contact workers	 3000000 500000	 24 8	 - 1	 1000 120

(a) Calculate frequency rate separately for regular workers and contract workers including weighted frequency rate.

(b) Calculate severity rate separately for regular workers and contract workers including days charged for the fatal accident.

(c) Comment on the safety performance between

For Factory A

FRW = $\frac{10 \times 10^6}{12 \times 10^5} = \frac{100}{12} = 8.33$ (for regular workers)

FCW = $\frac{2 \times 10^6}{25 \times 10^5} = \frac{200}{25} = 8.00$ (for contract workers)

Weighted Freq. Rate $= \frac{(10+2) \times 10^6}{1200000 + 250000} = 8.27$

SRW = $\frac{400 \times 10^6}{12 \times 10^5} = \frac{4000}{12} = 333.3$

SCW= $\frac{100 \times 10^6}{25 \times 10^4} = \frac{1000}{25} = 400$

For Factory B

FRW = $\frac{24 \times 10^6}{3 \times 10^6} = \frac{24}{3} = 8$

FCW = $\frac{(8+1) \times 10^6}{5 \times 10^6} = \frac{90}{5} = 18$

Weighted Freq. Rate $= \frac{(24+8+1) \times 10^6}{3000000 + 500000} = 9.42$

SRW = $\frac{1000 \times 10^6}{3 \times 10^6} = \frac{1000}{3} = 333.3$

SCW = $\frac{(6000 + 120) \times 10^6}{5 \times 10^5} = \frac{61200}{5} = 12240$

/Pll\vfn"   on

3000000+ 500000

1000x10" 1000 _..

3x10"   3 (6000+120) x 6 61200

considering 6000 man-days lost for I fatal accident (IS:3786-1983).

Comment : In case of regular workers, freq. rate of factory B is less than that of factory A and therefore good performance. In case of contract workers, the situation is reversed In case of regular workers, severity rate of both the factories is equal and therefore equal performance. In case of contract workers, the factory B has higher severity rate (which increased due to a fatal accident) and therefore comparatively poor performance. Comparing weighted frequency rates, total work performance of regular and contract workers of factory A is good.

6. For a medium size engineering factory, frequency rate ‘f’ and severity rate 's' for four consecutive years are given below in Table 1. Calculate the man-days lost per accident 'D' and Frequency-Severity Indicator 'FSI'. Arrange in descending order of safety performance, the four years for each index and for the overall performance rating. Use Table I and II for the final answer by filling the blanks.

Table 1				
Index	Year			
	1	2	3	4
F	17	15	10	9
S	174	175	83	108
D				
FSI				

Table 2				
Index	Year			
	4	3	2	1
F				
S				
D				
FSI				
Overall				

In Table - I, man-days lost per accident

$D_1 = \underline{S} \quad = \quad \underline{174} \quad = \quad 10.23$

$$\begin{matrix} & F & & 17 & & \end{matrix}$$

$$D_2 = \frac{S}{F} = \frac{175}{15} = 11.66$$

$$D_3 = \frac{S}{F} = \frac{83}{10} = 8.3$$

$$D_4 = \frac{S}{F} = \frac{108}{9} = 12.00$$

Frequency - Severity Indicator :

$$FSI_1 = \frac{F \times S}{1000} = \frac{17x174}{1000} = 1.719$$

$$FSI_2 = \frac{F \times S}{1000} = \frac{15x175}{1000} = 1.62$$

$$FSI_3 = \frac{F \times S}{1000} = \frac{10x83}{1000} = 0.911$$

$$FSI_4 = \frac{F \times S}{1000} = \frac{9x108}{1000} = 0.98$$

Arranging in descending order of Safety performance for each index.

For F	Because	Year F	=	4^{th}, 9	3^{rd}, 10	2^{nd} 15	& &	1^{st} 17
For S	Because	Year S	=	3^{rd} 83	4^{th} 108	1^{st} 174	& &	2^{nd} 175
For D	Because	Year D	=	8.3 3^{rd}	10.23 4^{th}	11.66 2^{nd}	& &	12.00 1^{st}
For FSI	Because	Year FSI	=	0.911 3^{rd}	0.98 4^{th}	1.62 2^{nd}	& &	1.719 1^{st}
For Overall	Because		S,D,FSI 3 times less	S, FSI 2 times less	F, D, FSI, 3 times less	F, FSI 2 times less and last		

The final answer is, therefore, given below by filing the blanks in both the Tables:

Table I				
Index	Year			
	1	2	3	4
F	17	15	10	9
S	174	175	83	108
D	10.23	11.66	8.3	12
FSI	1.719	1.62	0.911	0.98

Table II

Index	Year			
	1	2	3	4
F	4th	3rd	1st	2nd
S	3rd	4th	1st	2nd
D	3rd	1st	2nd	4th
FSI	3rd	4th	2nd	1st
Overall	Good	Satisfactory	Poor	Bad

7. In a factory in 1996, 80 accidents occurred when 200 workers worked for the whole year. In 1997. 120 accidents occurred with the same employment. Calculate the Safe-T-Score for the year 1997 and comment on the performance.

$$FR_{1996} = \frac{80 \times 10^6}{200 \times 48 \times 52} = \frac{80000000}{499200} = 160.25$$

$$FR_{1997} = \frac{120 \times 10^6}{200 \times 48 \times 52} = \frac{120000000}{499200} = 240.38$$

$$STS_{1997} = \frac{FR_{1997} - FR_{1996}}{\sqrt{\frac{FR_{1996} \times 10^6}{Manhours_{1997}}}}$$

$$= \frac{240.38 - 160.25}{\sqrt{\frac{160.25 \times 10^6}{499200}}} = \frac{80.13}{\sqrt{321.14}} = \frac{80.13}{17.92} = 4.47$$

As the STS 4.47 is more than +2, it indicates that the safety performance is worsened.

8. In a factory during 1992, 15 accidents took place when 70 workers were employed for six months. In the same factory when it worked for the whole year in 1996 with 90 workers, total 25 accidents took place. Calculate the Safe-T-Score for 1996 and comment on the performance.

Six months = 26 weeks.

$$FR_{1992} = \frac{15 \times 10^6}{70 \times 48 \times 26} = \frac{15000000}{87360} = 171.70$$

$$FR_{1996} = \frac{25 \times 10^6}{90 \times 48 \times 52} = \frac{25000000}{224640} = 111.28$$

$$STS_{1996} = \frac{FR_{1996} - FR_{1992}}{\sqrt{\frac{FR_{1992} \times 10^6}{Manhours_{1996}}}}$$

$$= \frac{111.28 - 171.70}{\sqrt{\frac{171.70 \times 10^6}{224640}}} = \frac{-60.41}{\sqrt{764.33}} = \frac{-60.41}{27.64} = -2.18$$

As the Safety-T-Score for 1996 is -2.18 i.e. less than -2, it indicates that the safety performance i improved.

9. Safety performance of two factories is as under

	Factor A	Factory B
Workers	750	1580
Accidents in pervious year	140	225
Accidents in current year	120	210
Working days in previous year	310	290
Working days in current year	160	240

Compare the Safe-T-Score of both the factories and comment on their Performance –

$$FR_P = \frac{140 \times 10^6}{750 \times 310 \times 8} = \frac{140000000}{1860000} = 75.26 \qquad FR_P = \frac{225 \times 10^6}{1580 \times 290 \times 8} = \frac{225000000}{3665600} = 61.38$$

$$FR_C = \frac{120 \times 10^6}{750 \times 160 \times 8} = \frac{120000000}{960000} = 125 \qquad FR_C = \frac{210 \times 10^6}{1580 \times 240 \times 8} = \frac{210000000}{3033600} = 69.22$$

$$STS_A = \frac{125 - 75.26}{\sqrt{\frac{75.26 \times 10^6}{960000}}} \qquad STS_B = \frac{69.22 - 61.38}{\sqrt{\frac{61.38 \times 10^6}{3033600}}}$$

$$= \frac{49.74}{\sqrt{78}} = \frac{49.74}{8.83} = 5.63 \qquad = \frac{7.84}{\sqrt{20.25}} = \frac{7.84}{4.5} = 1.74$$

Comment: Decrease in accidents and decrease in working days in both the factories do not give clear picture for comparison of factory A & B. Comparison of rise in frequency rates in both the factories indicates that there was more rise in FR of factory A than that of factory B and therefore the performance of factory A was comparatively worsened.

Safe-T-Score of factory A is 'more positive than that of factory B and this clearly indicates that the safety performance of factory A is poorer than that of factory B.

10. In a factory average labour force employed i 620. If the workers to be separated are 40 calculate the rate of labour turnover. If instead of separations, 36 are replaced with unavoidable separations, calculate the rate :

Rate of labour turnover

$$T = \frac{S}{F} = \frac{40}{620} = 0.064 \times 100 = 6.4\%$$

Considering replacement

$$T = \frac{R}{} = \frac{36}{} = 0.058$$

$$F \qquad 620$$

Considering unavoidable separation

$$T = \frac{R-U}{F} = \frac{36-4}{620} = 0.051$$

For examples of compensation due to industrial injuries and costs of accident, see Part 3 & 4 of this Chapter.

10.5 Benchmarking for Safety Performance

'Benchmarking means to find and follow the **"best practices'** to produce or get the best result in terms of performance, profit, productivity etc.

This process can be applied for safety performance also. The top management or the Safety Department can constitute a team of experienced supervisors or engineers to notice following things:

1. What are the defects in present practices to work on machines, vessels, equipment etc. and doing some hazardous jobs.

2. To think and search for the 'best practices" to remove above defects and to follow these best practices to reduce accidents and to improve the safety performance rates.

3. Such search of 'best practices' can be derived by interviews and discussing with own people or from outside work places where such best practices are followed and good results are achieved.

4. Then such decided 'best practices' should be implemented at desired places and when they give desired results, they .should be 'benchmarked' as a target for improvement.

5. Similarly from other observations and past record of accidents, other areas, work methods, plant, machinery and technology should be identified which need improvement for better performance. Then steps 2 to 4 should be repeated to search and follow the best practices for these areas also.

'Benchmarking' when followed, highlights strengths and weaknesses and suggests the ways and means for improvement.

"Matrix' can also be decided to benchmark certain areas of work like-

1. Reduction of accidents due to particular material, process or product.

2. Reduction in batch time or in manual exposure time.

3. Getting less rejects.

4. Getting more yield per unit of input.

5. Improving safety performance rate and winning 'awards' based on that.

Best safety standards should be listed and followed for best practices. The benchmarked standards should be equal to or lower than the statutory standards. The benchmarking process should be well documented for the use of others.

Many companies in the world have followed 'benchmarking' practices and improved themselves.

One example of project benchmarks decided and followed by one company is as under:

1. Reduction (to be achieved) in noise level by 5 dBA at identified areas.

2. Reduction (to be achieved) in average noise level exposure to 80 dB in 8 hrs in identified areas.

3. Reduction in dust exposure in Catalyst bagging area up to 8 "g/m" as against allowable of 10 mg/m^3.

4. Reduction in respirable dust exposure in RCH unloading area up to 2 mg/m^3 as against allowable of 3 mg/m"

5. Awareness of the health hazards of heat stress and reducing exposure.

Similarly any company can decide target areas and the benchmarked standards for them and make sincere efforts to achieve these standards.

11. BUDGETING FOR SAFETY

A budget is a plan for any period to show proposed or future anticipated and correctly estimated figures for money, material, time etc. to start or continue work for desired goals.

Mostly annual budgets are made for financial requirement. It may be by an individual, industry, office, State or Nation etc.

Discussion in foregoing Parts 3 to 9 reveals many elements of accident or safety costs and suggests need of budgeting for safety. It is important to know such costs for planning and budgeting for safety in industry.

11.1 Purpose and Procedure of Safety Budgeting :

It is obvious that every management should think about the effect of safety activities on its profits. Though it is true that the management likes to support safety programmes on humanitarian grounds, 'money and profit' is still a driving force for them as stated by R.B. Blake, a senior safety official of US Department of Labour, as early as in 1944. The main driving force behind the industrial safety movement should be the fact that accidents are expensive and substantial savings can be had by preventing them.

Money is an important measure to evaluate company performance and if it can be shown .that there is a financial return for money allocated to Safety Department, the top executive will certainly support it. Financial or economic benefits or costs savings by Safety Department should be properly exhibited to the top management in the form of budget for safety. .

Where there are high risks or serious hazards, the cost of the safety provisions can be far less than the cost of consequences. The world disasters have proved this. Estimates of such preventive activities are an important part of safety budget.

While discussing budgetary requirement, it should be emphasised that safety is a legal requirement as well as moral, humanitarian and social duty also and ultimately it results in productivity (uninterrupted production or less shutdowns), in reducing accident costs and maintaining workers' interest, morale and cooperation. . See Part-4 of Chapter-4 also.

Procedure for preparing and presenting safety budget may differ between factories and depend on size and status of them. In a small factory where there is no Safety Officer or Safety Department, a common person for all budgetary aspects should consider all safety items under a separate head of 'Safety or SHE provisions'

In a big or well organised factory, officers of safety or SHE department should sit together and design and fill a budget proposal form and after due discussion it should be finalized and sent to the top management for approval. Approved budget should be properly and timely utilized.

Budget procedure (process) has four steps.

1. Planning and projection.
2. Use of the money allotted.
3. Feedback or control by comparing real expenditure with the budgeted amount, and
4. Corrective action to re-adjust the budget for the rest of the period.

Essentials of good budget are - Planning, controlling and coordinating human activities for profit and productivity, link between past, present and future, clarity, certainty, flexibility etc.

Money to be invested (future estimate for budget purposes) in purchasing, fitting, maintaining and using safety equipment, instruments and devices can be considered as 'safety costs' if it is not considered as direct production or maintenance costs.

Money necessary for safety education, training and programmes is the direct cost for safety if it is not considered as general administrative or general education and training costs for employees.

Salaries to the safety personnel (own employees) should be included in general wage-bill of all employees but the payments (provision) to safety consultants, professionals, competent persons or experts (outsiders) can be considered as direct safety costs.

For a new or running plant, all costs for HAZOP, safety audit, risk assessment, design cost and costs for all built-in safety devices must be considered well in advance.

Estimates of direct and indirect costs of some predictable accidents can also give the figures for safety budget

Estimates for catastrophes, fires, emergencies, major hazards and safety analysis, assessment, audit, public liability insurance etc. should also be considered.

Normally following items are considered for safety budget:

1. Respiratory Personal Protective Equipment.
2. Non-respiratory Personal Protective Equipment.
3. Anemometer.
4. Gas tight suits.
5. Acid/Alkali/Chemical Splash Contamination Suits.
6. Fire Proximity Suits.
7. Flame retardant suits / overall.
8. Water Jell Blankets.

9. Safety Hand-lamps with charger.
10. Safety Torch (explosion proof).
11. Flame arresters for vehicles.
12. Safety showers.
13. First Aid Kit for ____ persons.
14. Levelling/ Printing Machine.
15. Safety Display Boards with Stand.
16. Display cabinet for safety items.
17. Air movers.
18. Roof top safety ladders (crowling boards).
19. Gas detection tubes.
20. Road closed barriers with board and stand.
21. Barrier cream.
22. Wind sock set / cloth.
23. Chlorine leakage control kit.
24. Ammonia leakage control kit.
25. Multi-gas detectors (e.g. CO, H2S, HC, Cl, NH,,).
26. Oxygen meters.
27. Hydrogen detectors.
28. Safety stickers.
29. Boiler / Inspection overalls.
30. Construction or up-gradation of Safety Centre for Exhibition and Training.
31. Painting / Re-painting cost for safety boards, banners, slogans etc.
32. Travelling charges to attend Govt Offices for safety or statutory work.
33. Fees, travelling and other expenses to attend safety seminars, programmes etc.
34. Vehicle charges for Safety Department.
35. Printing charges for safety information booklets, emergency instruction booklets, tremcards etc.
36. Stationary items, Xerox, and other printing charges.
37. Mock drill of On-site /0ff-site Emergency Plans.
38. Celebration of National Safety Day and other safety award programmes.
39. Computer software for gas dispersion models and consequence analysis etc.
40. New safety products like non-asbestos blanket, splash guard, flange guard etc.

The top management must make adequate provision for safety budget every year based on above considerations.

11.2. Consideration of Safety Performance Rates

Various types of safety performance rates are stated in foregoing parts 10.2 and 10.3.

Safety Officer or Department should calculate such different rates applicable to the factory. Cost of annual average man-hours or man-days lost and annual medical and other expenses for accidents happened during previous year should be considered and projected as budgetary estimate for the next year.

Expenditure (estimate) necessary for preventive measures to reduce such accidents (rates) should also be considered and included in the budget.

Performance rates and expenditure in controlling them should be compared from year to year to monitor decrease in such expenditure.

12. STATISTICAL TABLES AND THEIR CONCLUSION

A few selected tables are given here to study the industrial safety statistics of India and the State of Gujarat.

The most authentic sources such as Labour Bureau, Shimla, the Office of the Chief Inspector .of Factories, Ahmedabad and the Loss Prevention Association of India are used and acknowledged with gratitude. However, due to under-reporting, late reporting or no-reporting, the data is inadequate. Nevertheless it is the only tool to draw some inference.

Table 5.1 Number of Working Factories and Average Daily Employment

Sr. No.	State / UTs	Year	No. of working Factories	Average Daily Employment ('000)

Source : office of the CIF, Ahmedabad.

NB : (1) * For NIC - 1987 see Part 3.7 and for Accident Classification see Part 3.6.2 of Chapter-19.

(2) Figures group '101-1' means I accident (fatal+ nonfatal) of causation number 101 i.e prime movers, '117-21' means 21 accidents due to causation No. 117 i.e. electricity.

Conclusion of the above Statistical Tables :

(A) At All India Level (based on past figures) :

1. The highest number of factories are in Bihar, then in Maharashtra and Andhra Pradesh at second and third number. Considering Table 5.15, Gujarat is at No. 4. Employment wise Maharashtra, West Bengal and UP are at No. I, 2, and 3, and Gujarat stands at No. 4 (Table 5.1, 5.15 and 5.16).

2. After 1986 to 1991, number of injuries, incident rates (IR) and frequency rates (FR) have been decreased indicating an improved safety performance at all India level. But as mentioned by the source, ten to eleven States (including UP, Bihar, Karnataka, Delhi, Tamil Nadu, West Bengal etc.) had not sent the information for some or the other years. Therefore the inference remains incomplete (Table 5.2).

3. Comparing Gujarat with Maharashtra, MP, Orissa and Tamil Nadu, Gujarat has higher rate of fatal accident and therefore needs more attention (Table 5.4).

4. In 1992, in fatal and nonfatal accidents, Maharashtra was the first and Gujarat was second. in India. Considering injuries per 1000 workers, MP was the first and Rajasthan was second (Table 5.5)

5. Industry wise, in 1992, the highest fatal accidents were in basic metal industry, then in chemical and then in textile industries. Nonfatal accidents were highest in textiles, then in basic metal, machinery and equipment. Considering per thousand workers, fatal incidence rate was highest due to electricity, gas and steam, while non-fatal incidence rate was highest in basic metal industry and lowest in textile industry. Frequency rate (injury per one lakh man-days worked) is the highest in textile industry in respect of non-fatal accidents (Table 5.6).

6. Percentage wise highest fatal accidents are due to road accidents (27.2%). Then comes the causes of fire (12.2%), drowning (12.1%) and railway accidents (9.6%). Factory accidents are only 0.3%.Urispecified causes, being 18.5%, need detailed classification (Table 5.7, year 1994).

7. Causation wise in both the years 1990 and 1991, the highest fatal accidents were due to persons falling, then due to fires and electricity in descending order. The highest non-fatal accidents were due to material handling and machinery moved by mechanical power (Table 5.8).

8. The highest frequency rate in 1990 and 1991, was in Jute and cotton textile industry and the lowest in water works and leather works (Table 5.9).

9. International comparison states that Japan has the lowest fatal accident rate. Then comes USA and UK, both, at No. 2. India and Pakistan have the highest fatal accident rate! (Table 5.10).

(B) At Gujarat Level (based on past figures) :

1. Factories have been continuously increased in Gujarat from 24645 (in 1999) to 30110 (in 2005). The highest number of factories are in Ahmedabad city and then in Surat, Valsad and Vadodara districts in descending order (Table 5.15,5.16,5.17).

2. Fatal accidents varied between 246-175 (during 1997-2001). Non-fatal accidents seem to be decreasing. FR and SR indicate that frequency and severity are slightly increasing. In 1993 and 1995, non-fatal accidents were more in textile industry. But in 1994 and 1996 the scene was reversed (Table 5.18 & 5.19).

3. Causes of fatal accidents show that, during 1993 to 1997, the highest fatal accidents have happened due to –

1.	Striking against objects, falling	-	128
	on the flat, slipping etc.	-	115
2.	Falling from height	-	86
3.	Machinery run by power	-	79
4.	Electricity Molten metal and hot substances	-	73
5.	Fire and explosion	-	72

Then comes the causes of manual handling and struck by falling body.

If accidents classified as 'others' are exactly classified to the nearest specific cause, more fruitful information can be available (Table 5.20).

4. Industry wise majority (49.78%) of the total accidents in Gujarat are in cotton textile factories. Next in descending order are in engineering, chemical, silk, wool and synthetic fibre, basic metal, alloy and non-metallic mineral products, rubber, plastic and electricity factories. Other types of factories contribute less accidents (Table 5.21).

5. Causation wise the highest accidents (fatal ani •non-fatal) in Gujarat, m 1994, (See Table 5.2 and Part 3.6.2 of Chapter-19) were -

1.	Miscellaneous (not classified elsewhere)	3342
2.	Prime movers	2749
3.	Stepping on or striking against objects	1472
4.	Shafting and Transmission machinery	1011
5.	Struck by falling body	980
6.	Material handling	949
7.	Use of hand tools	710
8.	Falling from height	506
9.	Molten metal and hot substance	497
10.	Falling on the flat	474
11.	Lifting m/c (not moved by power)	395
12.	Falling into pits, excavation etc.	338

Other causes such as gas, fire, explosion etc. are still in descending order.

This analysis reveals that non-chemical causes contribute much more accidents than those contributed by chemical causes. This may be due to more manpower employment in non-chemical factories (about 30% in textiles, 10% in chemicals and 60% scattered in various other industries) and even in chemical factories not all workers exposed to chemicals. This should not result in under-estimating the high potentiality of chemical hazards. Many disasters have proved this fact. It is good that their frequency is less.

6. Major causes of non-fatal accidents are miscellaneous (others) in textile and non-textile factories, stepping on or striking against object, material handling, struck by falling bodies, use of hand

tools, falling on the flat, hot or corrosive substances, machine tools, falling from height and machinery moved by mechanical power.

7. Looking to the number of Safety Officers employed in some big factories, Gujarat is in good position. But it is noticeable that importance of safety officers is still not recognised. It is in the interest of safety to employs requisite safety officers to work exclusively for safety and accident prevention work Head of the Safety Department should be considered at par with other departmental heads and directly reportable to the top executive.

8. It is easily inferred from the above statistics that -

1 Textile, Chemical and Engineering factories should be the main target of accident prevention activities.

2 Most of the accidents are easily preventable by good- housekeeping training of workers, engineering controls and use of personal protective equipment, and

3 The safety statistics must be more accurate, because, majority accidents classified as 'miscellaneous' or 'others' suggest nothing specific and the accident prevention work becomes helpless in that dark (undetected) area. This visualises the importance of such safety statistics and their inference.

13. MANAGEMENT INFORMATION SYSTEM (MIS) FOR SAFETY

Management Information System (MIS) has become a powerful tool for industry, trade and business in the modern world. It should be user friendly and easy to understand. With the Age of Computers, the speed, capacity, accuracy and a variety of uses of Information has been tremendously increasing in almost all walks of life. Computers are useful not only for storing information but also for generating data, designing, programming, processing, controlling, running robots and microprocessors, communication, developing science, technology and management systems, analysing and using information, forecasting and personal use. We have entered the age of internet, web-site and information highways. The information (data-processing) must be accurate, pertaining to the point, concise, updated, meaningful, trust worthy and as per the need of the user.

The area of Safety, Health & Environment has also been delighted by an entry of computers and internet. The huge amount of information on accident statistics, health data and environmental aspects can, now, be easily stored, analysed, transmitted and used for many purposes. However in our country the use of computers for these areas is yet to be developed in majority of factories, particularly in medium-scale and small ones. Software should be developed for information in this vital area of safety, health and environment.

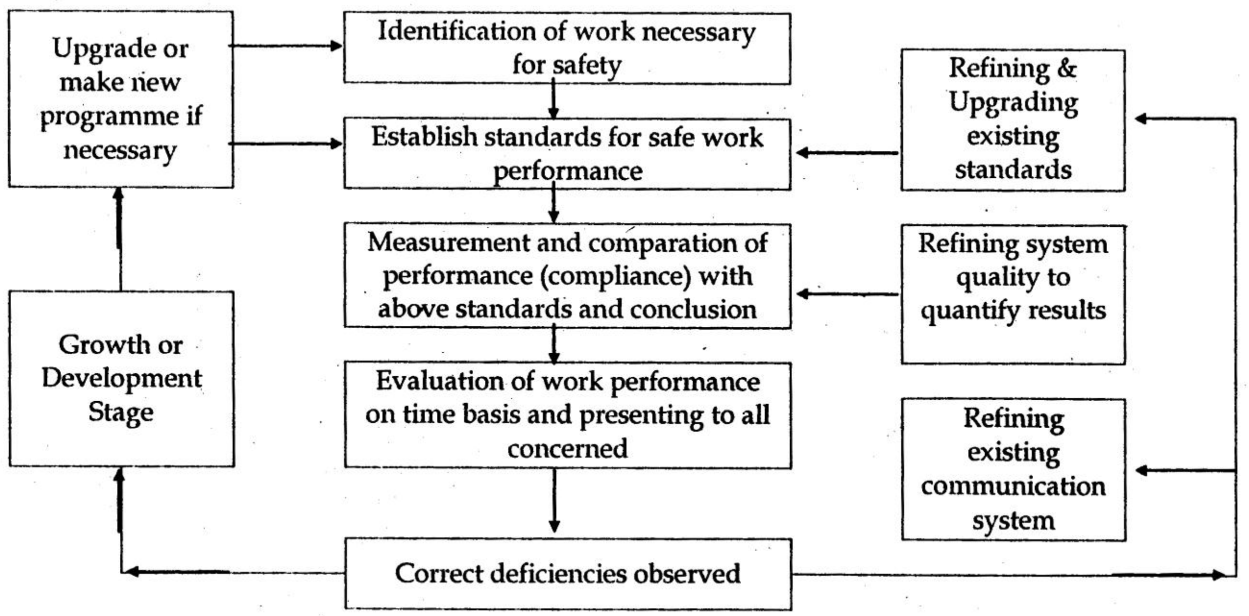
There should be effective MIS between Safety Department and the top management of the company to appraise the work being done by the Department. Similarly it should also be developed/extended for bottom line management and the outside authorities to provide quick and tabulated information in wide areas of safety, health & environment.

Computer, FAX, Internet, E-Mail and V-mail system can be used to devise various formats, tables, charts, symbols, graphs and documents to report, analyse, reply and store the information pertaining to accidents, statutory requirements, compliance, training programmes, safety meetings, future planning, budgeting, monitoring, work permit systems, safety appraisal reports, safety audits etc.

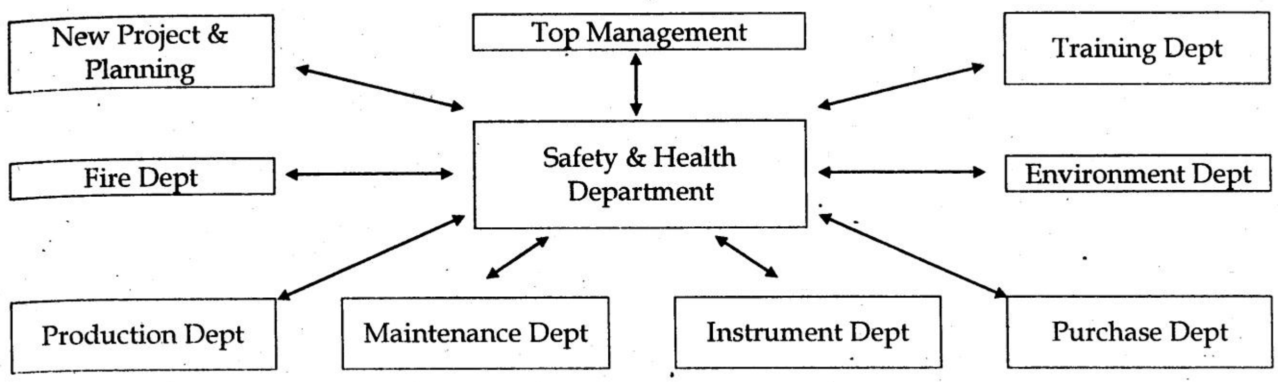
Types of information for safety may be of the following kind:

	Type	Examples
1.	Operational	Process control, fire protection system, inspection reports, test reports, environmental monitoring, training programmes etc.
2.	Legal (statutory)	Legal reports, returns, annexure. updated law. etc. regarding accident information industrial activity, compensation etc
3.	Tactical	Required for immediate need e.g procurement of safety equipment assessing training needs, daily reports etc.
4.	Strategic	Required for long term planning e.g on-site, off-site emergency plan layout planning.

MIS for SMS : MIS for Safety Management System should be designed as per own need. One general model may be of the following type :



A loop of effective communication system with safety department should be effectively arranged based on existing organisation set-up. A simple chart may be as under :



13.1 Sources of Information on Safety, Health & Accidents :

In our country the main sources to get such information are as under :

1. The Labour Bureau, Shimla & Chandigadh. Their state offices.
2. The Bureau of Indian Standards with its HQ at Delhi, four regional offices and some branches and inspection offices in major cities.
3. Loss Prevention Association of India with its offices at Bombay, Calcutta, Cochin, Hyderabad, Madras, Delhi and Visakhapatnam.
4. National Safety Council with its HQ at Bombay and Chapters in some cities.
5. The Central Labour Institute with its HQ at Bombay and Regional Labour Institutes (RLIs) at Calcutta, Kanpur and Madras.
6. National Institute of Occupational Health (NIOH), Meghaninagar, Ahmedabad - 380016.
7. The Mahatma Gandhi Labour Institute, Thaltej Road, Ahmedabad-380052.
8. Ministry of Environment & Forests, New Delhi.
9. Safety and Health Information Bureau, Sector 16, Vashi, New Bombay - 400 705.
10. Gujarat Safety Council, 4'h floor, Midway height, beside Panchmukhi Hanuman Temple, Near Kirty mandir, Kala Ghoda, Vadodara- 390 023.
11. The Council of Industrial Safety, Elphinstone Building, 10, Nariman Road, Fort, Bombay 400023.
12. The Safety First Association of India, 2nd floor, Stadium House, Nariman-Rd., Fort, Bombay 400023.
13. Directorate General of Mines Safety, Dhanbad826004, Bihar.
14. Ahmedabad Textile Industries Research Association (ATIRA), near Gujarat University, Navarangpura, Ahmedabad-380009.
15. National Institute of Training for Industrial Engineering (NITIE), Vihar Lake Rd., Bombay-400087
16. National Environmental Engineering Research Institute (NEERI), Nagpur-440010.
17. Indian Association of Occupational Health, C-62, Defence Colony, New Delhi-110024.
18. Industrial Health Organisation, Babu Vihar, 7/198, Swaroopnagar, Kanpur, UP.
19. Department of Industrial Health, Tata Services Ltd., Jeevan Vihar, 75, Apollo Street, Fort, Bombay-400 023.
20. Industrial Toxicology Research Centre, P.B. No. 80, Lucknow-226001.
21. Indian Council of Medical Research, Ansarinagar, Medical Enclave, New Delhi.
22. All India Institute of Hygiene and Public Health, 110, Chittaranjan Avenue, Calcutta-700012.
23. Occupational Health Research Institute, C/o BJ Medical College, Ahmedabad-380016.
24. Safety, Health & Environment Association, 2nd Floor, Vadilonu Ghar, Kasak Fuvara, Bharuch 392012, Gujarat.
25. Kamdar Swasthya Suraksha Mandal, Opp ESIS General Hospital, Gate No. 2, Bapunagar, Ahmedabad - 380 024.
26. Vyavsayik Swasthya Suraksha Mandal, 43, Shrinathdham Duplex, Swami Shivanand Road, B/h Dinesh Mills, Vadodara- 390007.
27. Greentech Foundation, 809, Vishwadeep Tower, Distt Centre. Janakpuri, New Delhi - 110058 (Website: www.greentech.org.)
28. Master of Industrial Hygiene and Safety Division, ISTAR Building, Vallabh Vidyanagar - 388120, Dist- Anand, Gujarat.
29. HSE Information Services, Caerphilly Business Park, Caerphilly CF83 3GG, UK.
30. Internet, websites and computer software are now available on the subjects of industrial safety, health and environment including that of British Safety Council, London, National Safety Council, USA, CSP (Certified Safety Professional) and CIH (Certified Industrial Hygienist) Examinations etc. See part 13.2 also.

The publications and periodicals of above institutions and Offices of the Labour Departments and Pollution Control Boards of various States also provide information on safety, health and environment.

NSC, USA publication 'Accident Facts' gives wide information on accident statistics of USA every year.

Some International organisations are as under :

1. International Labour Organisation (ILO), Geneva, Switzerland (Office in India at - 7, Sardar Patel Marg, New Delhi-110021).

   It has a separate branch for occupational safety and health. For collection and dissemination of Occupational safety and health information, it functions through

   1) International Occupational Safety and Health Information Centre (CIS)
   2) International Programme on Chemical Safety (IPCS) at WHO, HQ, Geneva.
   3) International Occupational Safety and Health Hazards Alert Systems. It is a part of the ILO International Programme for the Improvement of Working Conditions and Environment (PIACT).
   4) Clearing House for dissemination of information on condition of work.

   ILO publication **"Encyclopaedia of Occupational Health and Safety"** is worth mentioning for its great service on such information to the world.

2. World Health Organisation (WHO), Geneva, Switzerland (Office in India at World Health House, Indraprastha Estate, Ring Road, New Delhi-110002).
3. United Nations Environment Programme (UNEP)
4. Health and Safety Executive (HSE), Information Centre, Broad Lane, Sheffield 53 7HQ (UK).

There are many other such organisations in many countries of the world.

See reference mentioned at the end of each chapter, particularly of Chapter - 18 and 19., for ample material on health and safety.

In addition to law books, standards, codes, periodicals and publications (books), research reports, seminar or symposia reports, inspection or audit reports, accident case studies, meetings of specialists or experts and training programmes are also the main vehicles for the exchange of information on health, safety and environment.

Modern software like CAMEO, EFFECT, WHAZAN, HEGADIS, SAFETI, PHAST, BLEVE and Explosion packages -IIT, Kanpur, ALOHA, ARCHIE, CIRRUS etc. should be utilised and updated. Safety Data Banks should be created at National and State level. Global internet system should be utilised. MIS should be interlinked with National SHE System at all strategic areas.

Thus sufficient information is available from above sources. Only need is to implement it at the shop floor levels.

13.2 Websites on Safety -

Out of many websites on safety and health, some are mentioned below-

1. Chemical safety - www.chemicalsafety.co.in
2. Young Worker Health and Safety www.youngworkers.org
3. CROET Health & Safety Information www.ohsu.edu/ croet
4. Online purchasing of hundreds of safety products - www.compliancesafety.com
5. Risk Control Rating Systems (South Africa) www.rcrs.co.za
6. Free Safety Programs, Training Material, and Safety Information for Business & Industry www.safetyinfo.com
7. Applied Safety and Risk Management (Australia) - www.aplied-safety.com
8. Ergonomics web site with a lot of free Program, Training, ClipArt, Compliance information www.ergonext.com

9. On-line databases of information and downloadable software related to the environment, health & safety. www.ehsfreeware.com
10. National Safety Council, USA - www.nsc.org
11. NYCOSH website - www.nycosh.org
12. Det-Tronics, manufacturer of fire and gas safety systems - www.detronics.com
13. American Bio safety Association www.absa.org
14. Centres for Disease Control - www.cdc.gov/cdc.html
15. Electrical Safety Forum site - www.electricalsafety.com
16. Fall protection - Dynamic Scientific Controls www.fallsafety.com
17. University Safety Program- Florida State University - www.fsu.edu/~safety/
18. MSDS Surfer:
    Harvest MSDSs from the world-wide-web www.msdssurfer.com

13.3 Compilation, Collation & Analysis of Information:

At a factory or workplace level, information of hazards and past and current accidents should be collected first with facts and details. This is compilation. Then it should be put together subject or major head wise. Then in each head (viz. major hazards, minor hazards, accidents to persons, property losses, costs of accidents etc.), the information should be combined or arranged in a proper order for the purpose of easy understanding or comparing in detail. This is collation of information. Then it should be analysed or classified into subdivisions or subgroups to sharpen the information towards different subjects leading to some conclusion. This is analysis.

As an example, accidents of one particular year are first collected. This is compilation, (viz. Accidents for the year 1996, accidents costs, 1995 etc.). Then they are grouped (combined) together as mechanical accidents, chemical accidents, reportable and non-reportable accidents, fatal and non-fatal accidents, cost calculations etc. This is collation of information. Here comparison is possible. Mechanical accidents of factory A can be compared with those of factory B. If they are arranged in some order, say, date wise or code wise, it is also collation of information. But when the information is classified as male and female wise, day and night wise, different hazard or causation wise, equal cost wise, severity wise, frequency wise, body part wise etc., it is called analysis. This gives sharp or pointed information on a particular point subject to draw some conclusion.

This system of analysing data is useful to find out target areas of work and priority of remedial measures to concentrate on them. Manual exercise is reduced to a great extent if a computer is used for such work.

To foresee future possible hazards or risk estimation, by using various identification, measurement and evaluation techniques (Chapter 19) like HAZOP, HAZAN, fault-tree, event tree, risk and consequence assessment etc., detailed information can be compiled, analysed and used for accident prevention work.

Use of computer makes it easy to compile, collate, analyse and store vast information on identification of major hazard installations, risk analysis, safety audit, preparing on-site and off-site emergency plans, control pleasures, etc. and makes further easy to incorporate any additions and alterations at appropriate places to update the documents.

13.4 Modern Methods of Programming:

Such methods use computer as basic tool and software of required programmes. Therefore various software programmes are being developed and used for specific purposes.

13.4.1 Storing and Retrieval of Information:

Introduction of a computer is not much required for the modern generation, as it is taught to them from their early school-days. Therefore only a brief outline is given here. Main three visible parts of a computer are its monitor (or vision screen, also known as VDU i.e. Visual Display Unit), printer and keyboard. Central Processing Unit (CPU) is its internal part or brain that governs or controls all the work the computer does. Hardware consists of all physical components including monitor, printer, keyboard, CPU and everything else that can be touched, but not the floppy disks. Software are the instructions (programs) a computer needs to run the hardware i.e. to function as a word processor, data base manager, spreadsheet etc. A floppy disk. Zip, CD and pen drive store computer programs and data and can be read through a floppy or CD drive. Hard disk stores permanent memory until erased .or replaced. Graphics is a display of information in picture form. File is a collection of information stored on a disk. Programming means the process of providing a series of instructions to the CPU to get the desired actions. The main computer functions are input, output, storage and processing. CD writers are used to write a CD.

Information Technology (IT) and microchip have changed the world and accelerated the use of MIS. Silicon is the main element to manufacture microchip. PCB, microchip and microprocessor are working like brain and heart for information. They have reduced the size of document, equipment, stationary and files and are capable of doing many functions automatically.

Computer can store, process, change and print tremendous information. Capacity of storing is day by day increasing. Floppy, Zip, CD, VCD, Pendrive, Server etc. are the examples of progress. Hard disk capacity is also increasing. E-mail and V-mail transforms this stored information very fast. They connect all departments of a factory, all offices of a State or Nation and all countries in the world. Storing and presenting of MIS has become very fast and very easy. Laptop and palmtop are very handy. Handwriting is being replaced by keyboard writing. Correspondence and examination through keyboard have become a part of modern culture. Volumes of books and libraries have been reduced to small CDs.

Here 'retrieval' means taking back, finding or extracting information stored in a computer. Any information can be directly fed to the CPU or it can be copied by inserting floppy, CD or pendrive or through an internet. Such information stored in CPU can be recovered by a floppy or CD drive. Such information can also be modified, corrected, altered or added. Thus computer is useful in retrieving many information as per requirement. It saves too much time, labour and volume of work.

13.4.2 Computer Application and Use:

Use of computers for safety and health information systems became critical from 1.970s with the inception of Occupational Safety and Health Act in USA as much documentation, reporting and analysis were required by that Act. In our country, still it is in process.

Manifold use of computers for safety, health and environment is as under :

1. As its general use in science and engineering, computers are used for mathematical and statistical calculations, graphics, documentation, typing, printing, indexing, searching for literature, data

reduction, recording and maintenance of data, control of automated production lines (CAD, Computer Aided Design, CAM, Computer Aided Manufacturing and DCS process control) etc.

2. Automation of information paths and use of Safety Internet System.

3. Process control in plants and laboratories.

4. Accident and medical records.

5. Costing of accidents and losses.

6. Causation analysis of accidents or hazardous events.

7. Signal analysis and medical decision making, e.g. ECG analysis and diagnosis of heart problems, sonography, scanning, surgery etc.

8. Preventive Medicine and Epidemiology, screening, examinations of ill population and comparison of their data with the healthy population for early diagnosis of diseases.

9. Maintaining a long-time qualitative and quantitative record of chemical exposures to workers.

10. Maintaining environmental sampling and measurement data. Using for gas dispersion models and mathematical models for reliability engineering.

11. Preparing and maintaining periodical statements of accidents, injuries, causation wise break-ups, compensation and other costing, firstaid cases, nearmiss cases, safety training, status of compliance etc.

12. Safety reports, manuals, procedures, audit points, mutual aid systems and emergency plan items can be quickly stored, updated and reproduced.

13. Maintaining information of workplace conditions, engineering controls, fire and gas leak controls, administrative controls, medical controls, personal protective equipment and their selection, training programmes etc.

14. Maintaining employee demographics and job histories.

15. Scheduling of inspections, surveys, meetings, workplace monitoring, biological monitoring, condition monitoring, corrosion monitoring, maintenance programmes etc.

16. Reporting at any time to internal management or external statutory authorities or private agencies.

17. Keeping records of Material Safety Data. Sheets, Indian Standards, Statutory Provisions and Forms, Reports for Pollution Control Boards etc.

18. Statistical analysis by using ready-made or self-designed software.

19. Using robots, auto-controls and safety-devices to avoid accidents to persons and property.

20. Simulations to determine where hazards reductions would be more effective and the change in failure probability that would result. Useful to carry out hazard analyses, fault-tree analysis etc.

The special use of computers in addition to general benefits of software (Expertise, Up-to-date information and Improved management) is for Accident recording and analysis. Information on chemical hazards. Audit recording and analysis etc. Data on such points are as under:

1. Automatic printing of statutory and other safety forms.

2. Automatic generation of periodical reports.

3. Analysis of near misses in the same details as injury accidents.

4. Multiple records of injury, property and vehicle damage from the same incident

5. Linked incident costing so that reports can automatically include details of the costs involved.

6. Automatic summaries and their graphical displays.

7. On-line computing using own computer to contact the library or publisher's computer to obtain and read off the information required.

8. CD-ROM (Compact Disc - Read Only Memory) and player for the computer and special software on chemical hazards and control technology. The information from the disc is displayed on the computer screen. Conversely, information in the computer can be copied on CD by using CD writer.

9. Use of floppy-discs, CDs and Pendrive to read off the information.

10. Database from CAMEO, COSHH, APELL etc. and onsite and offsite emergency plans (see Chapter-2 for definitions).

11. Safety audit and environmental audit details by using a set of audit questions (also known as audit protocol). Such audit software packages include:

    a) The ability to edit the audit questions and add audit questions as new risks are identified.

    b) The ability to add guidance for the auditors to specific questions, including details of any relevant standards.

    c) Displaying two or more sets of audit results on the screen at a time and to compare them.

    d) Graphical display of audit summaries.

    e) Automatic generation of audit reports, including action plans.

    f) Diary facilities to assist in managing an audit schedule and keeping track of recommendations for remedial action.

13.4.3 Advantages and Disadvantages of Computerized System

Advantages of computerised information systems are -

1. Ready availability of data and ready reproduction (printed copy) of the stored data.
2. Elimination of monotonous or exhaustive manual labour.
3. No need to keep duplicate records (copies). Reducing files and their storing space. A shared information can be seen at many places (i.e. in different department, conference hall etc.).
4. Improved communication with neat, clean and correct copies. Electronic mail systems can facilitate communication within and between facilities and within short time.
5. Data standardisation and accuracy.
6. Improved analytical capabilities. Analyses not manually practical, can be easily done by a computer. Graphs and Chartes also available.
7. Cost savings by increasing employee productivity, decreasing manpower etc.

Disadvantages (limitations) of computerised nation systems are

1. According to circumstances, need of computers is not always justified. Sometimes it may be premature or totally unjustified on economic grounds.
2. Computers' limitations should be understood. They are not designed for automatic information generation or processing. An operator is required to make data-entry or supply basic information (programme) to computers and his error can give wrong or incomplete information or sometimes erase it and manual search becomes necessary. Mistakes can become repetitive if not corrected in time.
3. Computers can suggest references to documents. They cannot eliminate the need to go through these documents to locate the required information.

4. A typical virus can wash out all information stored in the computer. Then retrieval or restoration of data becomes necessary.
5. Manpower reduction for unemployement.

13.4.4 Hazards and Controls of Working on Computer:

Following hazards have been reported:

1. Ergonomic problems may arise with computer operators. Computer room should not be too noisy, too warm, too cold, unpleasant, humid, congested or poorly lighted. Wrongly designed furniture and sitting arrangement can cause pain in neck and back.

2. Radiation from screen (VDU) and bad contrast can cause eye fatigue and headache. Antiglare ' screen or auto glare (strain) removal device is useful.

3. Psychological problems like monotonous work in isolated position, waiting times, intense concentration (e.g. traffic control) may also arise. Good design and layout of computer room, equipment, fire protection system, records protection, utilities protection and safe storage practices are necessary.

4. A study report of Devis School of Medicine, California, USA, says that pain in waist, shoulders and neck, tension on eyes and legs pain due to decreased blood-circulation are all ill effects of constantly sitting on key-boards. Long sitting in particular posture is hazardous to health. Ergonomic design of sitting and working arrangement and training to computer operator are essential to reduce such pains (News 11-1-2000).

5. It is also reported that using a computer mouse for a long time exposes some people to carpal tunnel pressure levels that may lead to repetitive strain injury to the wrist and hand. This was said by David Rampel, Director of the Ergonomics Program at UC San Francisco (News, Bridges, COEH, June 2000).

6. It is reported that increasing use of computers will develop cataract at younger age and in the year 2050, most of the people will be able to read on computer only after laser surgery (News 23-8-2000).

7. One study report in California revealed that the women working more than 20 hours in a week on video display unit have 80% more chances of abortion than those not working in this way.

8. Another survey in western countries states that 10 to 15% employees working on computers daily complain of body pain and eye strain. Other 40 to 50% employees complain occasionally.
   As per one Japanese study, eye flickering reduces to 7/min. from normal level of 22/min. Eye watering, burning, temporary dimness or vision lose, to see double things etc. are known as computer vision syndrome (CVS).
9. Indian people are habituated to work in 27°C temperature. If they are compelled to work in 17 to 23°C temp, (VDT operators), their health is adversely affected.

Control Measures:

Ergonomists suggest many remedial measures to reduce 'computer-trauma' and other health effects. Some of them are as under:

1. **Computer Vision Syndrome (CVS) -** Eye strain is mainly due to monochromic light or burden of glare (excessive light) on eye. Pain in neck or back is caused due to improper seating of monitor from our face. Monitor should be kept at 10 to 15° below the angle of eye level and 20 to 28 inch away from the face. There should be a balance between monitor light and room light. In darkness, computer should not be operated. Eyes should be turned aside and closed for a few

seconds at the interval of half an hour. A vision guard programme is available to remind this relaxation exercise. It should be loaded in the computer.

2. Hand below the elbow should remain parallel on computer-table, and fingers on key-board.
3. Table and chair should be fully flexible so as to rearrange as requirement. Specially designed back rest necessary.
4. VDU should be so placed that the sight will fall on the correct place on the screen. Computer screen should remain below the eyes so that the eyes and neck are not unnecessarily raised.
5. Key-board should be thin, easy to operate and move and separate from the display unit..
6. Noise from printer should not be more than 55 dB, otherwise hood is required.
7. Operators having sitting work and standing work should be interchanged by job rotation. This will relax the contracted muscles and maintain the body tone-up.
8. Eyes should be examined by Ophthalmologist for internal defects if any. After the age of 40, spectacles become necessary to see from a short distance. Considering the length between the eyes and the computer screen, the special spectacles (not bi-focal) should be worn while working on computer.
9. Lighting, shining and colour have also some effects. They should not be excessive.
10. At every 15, to 30 minutes, eyes should be turned away from the screen to see aside or take rest raise-or move hands, press fingers etc. Legs should be freed from one position. They should have rest support.
11. Working hours on computer should be reduced with increasing age or difficulty.

13.4.5 Causes of MIS failure:

They are of the following types :

1. Insufficient, incorrect or ambiguous information.
2. No two-way communication.
3. Confused reporting.
4. Poor exchange of information.
5. Poor system of communication.
6. Insufficient employee involvement.
7. Untrained employees.
8. No system of feedback receiving for the improvement of MIS.
9. No advanced planning to meet and control emergencies.
10. No advance planning for protection of MIS, e.g. Steps to prevent virus in computers.

Such causes should be detected and removed as early as possible.

13.4.6 Status and Future Goals of Computer Utilization in SHE Services:

Status of computer utilization is being increased and spreading very fast. Today we are rapidly entering in the age of information technology, information highways, internet systems, super-computers to design, scan, develop, store, exchange and transmit data for many complex systems and for many purposes. Paper files and record rooms are all shortened and it seems that in every walk of life computer has to" play some role. Safety, health and environment being the vital subject, cannot remain without the use of computers. Process technology, instrument and control devices, hazard control technology, emergency planning including training, education and information to workers, public, management and Government ... everywhere use of computers is being increased.

One earlier software for SHE services is CAMEO i.e. Computer Aided Management of Emergency Operations. It is a Computer Software Package developed by the Environment Protection Agency (EPA) of USA. The CAMEO software is made operational and available from the National Safety Council, Mumbai. It was explained with the APELL/ CEP workshops at Manali, Mumbai, Kanpur, Cochin, Haldia and Vadodara during 1992 to 1995.

CAMEO gives emergency planner, first responder (fire brigade, police etc.) or safety professional vital information to help handle chemical accidents safely.

What does CAMEO provide :

CAMEO provides tools to help address issues, including

1. Response information for over 4000 chemicals commonly transported.
2. Database templates to help manage chemical inventory information.
3. A mapping capability that allows to identify the proximity and potential hazard posed by facilities to sensitive populations.
4. The ability to create scenario using hazard analysis calculations to assist .in emergency planning and overlay the estimated vulnerable zone on maps.
5. A drawing capability to pinpoint locations of chemicals stored in-community or facility floor plans that are created.
6. An air dispersion model that can be used to help evaluate spill scenarios and evacuation options for 700 airborne toxic chemicals (this features is available for the Macintosh and is being developed for CAMEO DOS).

For other Software, see Part 4.3(c) of Chapter-19.

13.4.7 Integration between Departmental MIS:

Because of wide use of computer software for many purposes, use of internal and external e-mail and information transfer systems, transferring presentation from any computer to the computer of conference room or auditorium, using stored or communicated information for design, production, sale, purchase, taxation, audit, assessment etc, good and effective integration of MIS between all departments is essential and constantly-required.

Information on safety management system, SOP, PPE, safety work permits, statutory and other safety provisions, forms and annexure, training subjects and schedules, safety Suggestions, compliance etc is required by many departments from safety department. Similarly safety department needs feedback and other information from other departments. This is not possible without effective integration of MIS between all departments.

Therefore continuous integration between departmental MIS should be maintained and updated.

EXERCISE

1. Comment on the following Statements by giving your opinion:

1. Accident problem is not a big problem. Adequate and sufficient data are available.
2. Accident cost to the injured person is not much. He is insured and therefore no need to worry.
3. Indirect cost of accident is less than the direct cost.

4. Indirect costs of accident are not visible and not important.
5. Preventive' costs may be less than the total costs of accidents.
6. Management should realize the costs of accidents to improve productivity.
7. Cost calculation of accident is not difficult. Its record can be maintained and well utilized.
8. How to fix 'man-days lost' for death of a worker, is a problem. No figure is fixed for that
9. If frequency rate is reduced, severity rate will also be reduced.
10. 'Reportable lost time injury' is more important than lost time injury' for the purpose of safety.
11. DH and FSI are same. DH denotes degree of improvement.
12. Safety activity rate takes four things into consideration..
13. A serious accident causes much effect on severity rate but little effect on frequency rate.
14. Frequency rate can be used to compare present safety performance with the past.
15. Take care of frequency rate, then the severity rate will take care of itself.
16. Frequency rate is a better base of comparing two or more units than the severity rate.
17. No 'injury rate' is capable of giving complete picture of safety performance.
18. Injury rates also represent properly damage and time losses.
19. Injury rates have drawbacks..
20. 'Man-hours worked' taken from 'Attendance Register' do not give correct picture.
21. 'Severity rate' does not represent of severity of pain and suffering of a worker.
22. There is no need to prepare a 'Safety Budget' separately. General budget can take care of it.
23. Safety budget has many items to include.
24. Safety performance rates should be considered while preparing a safety budget.
25. It is difficult to up date labour statistics.
26. Year-wise fatal and nonfatal injuries are useful to know safety-status.
27. Cause-wise injury figures have meaningful message.
28. Incidence rate and Frequency rate both are useful for comparing 'status' in safety performance.
29. Four types of information are generally required for safety.
30. Computerised information system has many advantages.
31. Computerised information system has some limitations also.
32. There is no hazard in working on computers.
33. Ill effects of constantly sitting on keyboards are many.
34. Ergonomic measures to reduce 'computer trauma' are important.
35. MIS cannot fail.

2. **Write Short Note OR Explain in brief:**

1. Need of statistics of safety.
2. Magnitude of the safety problem.
3. Inadequacy of safety data.
4. Accident cost to the injured person and his family.
5. Direct and indirect costs of accident.
6. Frank E Bird's Iceberg concept of indirect costs.
7. Factors of Hidden Costs.
8. Accident cost to the society.
9. Limitation of Accident Cost Data.
10. Utility of Accident Cost Data.
11. Utility of Safety Performance Rates.
12. Significance of Injury Rates.
13. Drawbacks of Injury Rates.
14. Benchmarking for safety performance.
15. Items of Safety Budget.
16. Use of computers for safety information.
17. Hazards of working on computers.

18. Computer trauma and remedial measures.
19. Causes of MIS failure.
20. Future goals of computer utilization in SHE services.

3. Explain or Discuss with details :

1. Why do we need safety statistics? How is it useful?
2. Who do suffer the costs of accidents? In what way? And of what types?
3. Explain Heinrich's list of indirect costs of accident.
4. As a Safety Officer, design an Accident Investigation Form with necessary contents.
5. Explain various types of 'injuries' under IS:3786, or the WC Act or ESI Act.
6. Explain how injury rates are useful and what are their limitation.
7. Explain the purpose and procedure of safety budget.
8. Explain the process of Compilation, Collation and Analysis of safety Information.
9. Explain modern methods of programming.
10. Explain manifold use of computers for SHI services.
11. Discuss advantages and disadvantages of computerised information system.
12. Discuss hazards of working on computer; and state their remedial measures.
13. What information is supplied by CAMEC software?
14. How can we integrate MIS between different departments?
15. What future do you foresee of computer utilization for SHE services ?

CHAPTER – 6

Safety Management

THEME

Before proceeding toward safety management, it is necessary to know about the general management.

1. THE CONCEPT OF MANAGEMENT

The concept of management has to origins Indian and Foreign.

1.1 An Indian Origin

Before considering the modern concept of management, it is interesting to know our ancient concept of management.

Oldest Indian concept is that the God is the Supreme Manager who manages this universe. He is the creator, protector and killer. These managerial functions are done by Brahma, Vishnu & Mahesh. He plans, creates, controls, directs; governs, organises, evaluates, motivates, communicates and co-ordinates all activities. He is the King of kings, the Great Administrator and the Manager. We still believe this.

Then with the rise of jktk (King), jkT;O;oLFkk (State Affairs or Ruling) and U;k;O;oLFkk (Law & Justice) for iztk (Public), our old management ideology moved and developed around King, Kingdom and his administration. The words jkT;/keZ] iztk/keZ and /keZ were giving and still giving many duties for better management.

Ramayana, Mahabharat and Kautilya's Arthshashtra describe elaborately ancient concepts of management. Some citations are given below :

vHkkoks ok izHkkoks ok ;=k ukLR;FkZdke;ks% A
lekts LokRe:iRrokr~ /keZpdz izorZue~ AA

Where wealth and desires are neither absent or dominating, by its own, Dharmachakra i.e. the best and dynamic management prevails in the society.

The Rugved states:

Lekuks ea=% lfefr% lekrh lekua ozre~

We should move by one common inspiration, come to a common decision and accept common rules and regulations.

Raja was the guardian of the social constitution. It is said

o.kkZJe/keZizfrikydks jktk A

Raja was the executor and protector of all sections of people and their /kkfeZd ways of life. (The word king or monarch is not a real synonym of Raja as the word 'religion' is not the synonym of /keZ).

How was the concept of self-management ?

u jkT;a uSo jktk·lhr
u n.M;ks u p nkf.Md % A

/kesZ.kSo iztk losZ
j{kfUr Le ijLije~ AA

There was neither the State nor the State Officials, neither the punishable nor those authorised to punish. The people used to protect each other only on the strength of Dharma.

But such ideal condition did not last longer and gradually the administration of the State and Raja were immerged in the society. Then Raja started administration, planning and management.

lHkk or 'assembly' was defined by Janak as under

u lk lHkk ;RFk u lfUr lUrks A
u rs lUrks ;s u Hk.kfUr /keZe~ AA
jkxa p nks"ka p igk; eksga A
/keZe~ Hk.kUrk p HkofUr lUrks AA

Unless any assembly is attended by a few exponents of Dharma, those who are detached in mind, are faultless in expression and action and have no allurements, the same cannot be said as properly constituted or held. This describes the qualitative quorum for assembly. Such assembly will manage the best. The deep wisdom of this constitutional provision is unchallengeable.

jktk Hofr Hkwrkuka fo'okL;ks fgeokfuo A % 'kkafrioZ

In every respect of public policy, the State should be worthy of reliance of people. Such are the managerial functions of the State as conceived by Indian thinkers of old age. (thousands years BC).

The whole trend of Ashram Dharma was based on non material pursuits of life and the management by minimum (MBM).

;kon~ fHkz;sr~ tBja rkon~ LoRroa fg nsfguke~ A
vf/kda ;ks·fHkeU;sr l Lrsuks n.MegZfr AA

So far one takes as per requirement of his stomach, it is his own. He who takes more than this, is the thief and liable for .punishment.

The managers (leaders of the society) are advised by Gita:

;n~ ;n~ vkpjfr Js"B % rRrnsosrjks tuk% A
l ;Rizek.ka dq:rs yksdLrnuqorZrs AA

The behaviour of the top men is followed by others. What he establishes, people follow it. This is the true method of inculcating discipline - the influence of a high ideal and example at the top level (management).

Kautilya Chanakya is the great father of Indian Administration and Management for State Affairs of his age. He says:

Izktklq[ks lq[ka jkt% iztkuka p fgrs fgre~ A
ukRekfiz; fgra jkK% iztkuka rq fiz;a fgre~ AA

In the happiness of public, lies the happiness of the Ruler (Raja). In the interest of public, lies the interest of him. It is in his interest to carry out such functions which are liked by the people and not merely by him (Example of Shri Ram).

Various management, administrative and executive functions are well defined by **Kautilya** in his Arthashashtra (Rajniti). Management of education, ministers, detectives, ambassadors. State Officials, mines, horse stable, weapons, weights and measure, income and revenue, agriculture, places for execution of death sentence, transport and vehicles, tank (Ratha), military, the Chief of Army and their functions, currency, citizens, agreements, marriage, heritage, house building, sale of property, disputes, loan, servants and labour, partnership, exchange, aggression, gambling, protection of people, theft, fine and punishment, welfare, duties of public servants, implementation, peace, industry, king, rules of friendship, war, treatises, behaviour with enemies, habits, power, weakness, situation, loss and profit, methods of defence, types of war and policies, experiment, other policies, establishment of peace etc. are described in details.

No such document was existing in the world in 'Kautilya's times (some 2500 years ago). This is his wonderful and singlehanded unique contribution on so many subjects •of management.

1.2 The foreign origin :

Since human beings started living in groups and families in ancient time, some thoughts of leadership and management were evolved from the beginning.

Egyptian papyri recognised the importance of organisation and administration in the bureaucratic states of antiquity long back in 1300 BC

Confucius, in ancient China suggested public administration and admonitions to choose honest, unselfish and capable public officers.

The Athenian commonwealth in early Greece .indicates managerial function for councils, courts, officials and board of generals. Socrates' definition of management as a skill separate from technical knowledge and experience is close to current understanding of the function.

The existence of the Roman magistrates with their functional areas of authority and degrees of importance, indicates characteristics of organisation.

The Sumerian civilisation had a system of tax collection in 300 BC

The Roman Catholic Church, the Pyramids of Egypt, the cameralists (German and Austrian public administrators in 16th to 18th century), the Chinese Civil Service and old military organisations of earlier centuries present some forms of the old foreign concept of management and administration.

See Part 5.1 of Chapter-1 also.

2. EVOLUTION OF MANAGEMENT THOUGHTS AND PRINCIPLES

Management thoughts are of two types - Old and Modern. They are discussed below.

2.1 Old Management Thoughts and Principles:

As stated in Part I, our Vedas, Rushies and Kautilya are the pioneering contributors to the origin of management thoughts of their time.

Some foreign contributors and their thoughts are given below.

	Contributor	Thoughts
1.	Robert Owen (1771-1858)	Human resources are more important than machines. He started on' human relations and suggested shorter working hours, rest intervals, training of workers in hygiene, canteen, children education, housing facilities etc. He is known as the father of personal management and co-operation.
2.	Charles Babbage (1791-1871)	Use of science and mathematics to factory operations. Division of work. Applicability of time & motion study. Cost reduction by improved methods. Participative decision making. Specialisation. Work measurement and optimum use of machines.
3.	Henry Varnum Poor	During 1849 to 1862 he watched the American railroad system and suggested three principles for managers- organisation, communication and information. He suggested 'Managerial System' of accountability, summarising costs, revenues and rates, leadership and feeling of unity.
4.	Henry Robinson Towne (1844-1924)	He urged the combination of engineers and economists as industrial managers, exchange of experience among managers and art of workshop management.
5.	James Watt and Mathew Robinson Boulton (1796-1848	Market research and forecasting standardisation of components and parts, production planning, planned machine for better workflow, statistical record advance control reports and cc accounting procedure, employ sickness benefit scheme and scheme for developing executive.
6.	Henry Metcalfe (1847-1917)	Record of observations & experiences for cost estimates. System of time cards and material cards to inform the management good work of the workers. H system of management was put record by the America Management Association.

Thoughts on Scientific Management:

- F.W. Taylor, Henri Fayol and subsequent thinkers developed the thoughts of Scientific Management since the beginning of 20th century.

F.W. Taylor (1856 - 1915) : Frederick W. Taylor is called the founder of modern scientific management. His famous work 'The Principles of Scientific Management' was published in 1911. His main concern was with achieving efficiency of human beings and machines through time and motion study. He suggested following functions for managers :

1. Replacing rule-of-thumb methods with scientific determination of each element of a man's job.
2. Scientific selection and training of workmen.
3. Co-operation of management and labour to accomplish work in accordance with scientific method, and
4. A more equal division of responsibility between managers and workers, with managers planning and organising the work.

Henri Fayol (1824 - 1925) : Henri Fayol the French industrialist published his acute observations on the principles of general management in 1916 in French and divided all activities of industrial undertaking into six groups :

1. Technical (manufacturing or production).
2. Commercial (buying, selling and exchange).
3. Financial (search for and optimum use of capital).
4. Security (protection of property and persons).
5. Accounting (including statistics) and
6. Managerial (planning, organisation, command, co-ordination and control)

Fayol identified five elements or functions of management process as under -

1. Planning to foresee and provide means for the future
2. Organising to provide a business everything useful to its functioning e.g. raw materials, tool capital and personnel
3. Commanding to maintain activity among personnel
4. Co-ordinating to unify and harmonise all activities and efforts
5. Controlling to see that everything occurs in conformity with established rules and expressed command

Fayol published his book 'Administration Industrielle et Generale' in 1916. It was also published in English in 1949 under the title ''General and Industrial Management'.

Fayol gave ‘General Principal of Management’ as -

1. Division of work.
2. Authority and responsibility.
3. Discipline.
4. Unity of command.
5. Unity of direction.
6. Subordination of individual to general interest.
7. Remuneration of personnel.
8. Centralisation.
9. Scalar chain.
10. Order.
11. Principle of equity.
12. Stability of tenure of personnel.
13. Initiative and
14. Esprit de Corps i.e. unity of effort through harmony of interests.

Fayol advocated the universality of management concepts and principles. He said that managerial functions and principles are applicable to all types of organisations.

Mary Parker Follett (1868 - 1933) : She analysed the problems of power, authority, conflict and control from a psychological viewpoint and revealed the operation of social process and group dynamics in industrial organisation. She contributed in the areas of motivation, leadership, authority and co-ordination and recognised management as a profession.

Her management thoughts can be summarised as (1) Constructive conflict (2) Laws of the situation (3) Leadership (4) Authority & Responsibility (5) Principles of Co-ordination.

George Eiton Mayo (1880 - 1949) : His thoughts concluded from his 'Hawthorne experiments', put stress on human and social factors in industry and called the 'Father of Human Relations Approach to Management'. He said that influence of inter-personal relations, attitudes of supervisors and other social and psychological factors is more than' the influence of working conditions. Worker respond to total work situation including their care, recognition, participation, work design etc.

Chester I. Barnard (1886- 1961) : His thought can be summarised as -

1. Concept of organisation.
2. Formal and informal organisations and interaction between them.
3. Elements of organisation with the systems of fictionalisation, incentive, authority and logical decision-making.
4. Functions of the executive.
5. Motivation.
6. Organisational equilibrium and
7. Executive effectiveness.

He is regarded as the spiritual father of the social system school. He stressed upon leadership, motivation, informal organisation, status, acceptance of authority and communication.

Herbert A. Simon : He was an American political and social scientist (1978). His thoughts were focused on -

1. Concept of organisation.
2. Decision-making.
3. Bounded rationality.
4. Administrative man.
5. Communication and
6. Influence.

Rensis Likert (1903 - 1972) : He was a leading social psychologist. He classified 'management styles' in four categories - Exploitative autocratic. Benevolent autocratic, Participative and Democratic. He developed the concept of linking pin' to integrate individual and organisational goals. He and his associates also developed a measuring instrument (scale) to evaluate leadership styles of managers.

Douglas McCregor (1906 -1964): He is known for his theory of motivation (theory X and theory Y). He stressed on human relations and 'satisfied and happy employees' as an objective of organisation.

See Part 8.3.7 of Chapter 3.

Chris Argyris : His books on management were published between 1959 to 1971. He is known for his immaturity-maturity model of personality. He told that employees must be given responsibility, authority and increased control over the decision-making to improve their work environment.

Peter F. Drucker : He was a leading management consultant and a prolific writer. Born in 1909, was a leading proponent of managerism. He has written 20 books on different facets of management He considers management as the dynamic, life giving element in an organisation. His writings are landmarks in management. He has exercised major influence on contemporary management thought and practice. His thoughts in brief are as under -

1. Nature of management -it is a 'practice' rather than profession.
2. Managerial functions - To manage managers, workers and the work.
3. Organizational structure.

4. Decentralization.
5. Management by objectives (MBO) - Philosophy resting on human action, behaviour and motivation. He suggests 8 key areas in which clear objectives must be laid down - market, innovation, productivity, physical and financial resources, profitability, managerial performance and development, worker performance and attitude and public responsibility.
6. Futurity - He was worried by rapid progress of technology and its impact on society.

H. W. Heinrich : He is called the father of 'safety management'. His famous book'- Industrial accident prevention - A Safety Management Approach' was first published in 1931. He is famous for his accident causation theory and five fundamentals of accident prevention. He has explained safety functions for supervisors and managers. See Part 7.1 and 8.2 of Chapter-4.

2.2 Modern Management Thoughts (Recent Trends) :

Development in technology, science, trade, business and employment have increased the size and complexity of management and organisation. Quality standards, consumers awareness' after sale-service, mass production, automation, human resource development, stress on training, trade union demands and use of computer based programmes are adding new trends in management. Public and private both the sectors have increased. Challenges and manifold responsibilities are increased demanding technocrat role of the managers and demand for MBA study is also increasing.

Areas of such modern trends are

1. Information technology.
2. Electronic Communication - advanced computers, FAX. Email. Internets.
3. Importance of human relations.
4. Challenges by trade-unions.
5. Impact of Government policy.
6. Facing Government authorities (intervention).
7. Marketing.
8. Publicity.
9. Competition.
10. Leadership.
11. Futurology.
12. Flexible Organisation.
13. Changing situations and decisions.
14. Variety of goals.
15. Professionalism i.e. increasing studies of management subjects.

New developments, systems and approaches in all above areas, provide Modern Management Thoughts (new trends). Thus, the management thoughts are changing and depending on modern trends.

3. DEFINITIONS, NATURE AND IMPORTANCE OF MANAGEMENT:

Definitions on management are available as under:

1. The accomplishment of desired objectives by establishing an environment favourable to performance by people operating in organised groups.

2. It includes the managerial functions of - (1) Establishment of objectives and (2) Process of planning, organising, controlling and directing i.e. motivating and co-ordinating to attain those objectives and innovating to improve the objectives for the future -**Rustom S. Davar.**

3. It is a multi-purpose organ that manages a business and manages managers and manages worker and work-**Peter Drucker.**

4. It is the art of getting things done through people - **Lawrence.**

5. It is the art of getting things done through and with people in' formally organised groups **Harold Koontz**.

6. The task of creating the internal environment for organised efforts to accomplish group goals. In co-ordinating group activity, the manager plans, organises, staffs, directs and controls.

7. The function of executive leadership anywhere **- Ralf C. Davis.**
8. Management is a distinct process dealing with group activity.

9. The objectives are achieved through establishing salient relationships between human and nonhuman resources.

10. The manager does not necessarily perform things for himself, but, accomplishes objectives through others in the group situation.

11. It is the art and science of decision making and leadership - **D.J. Clough.**

12. It is an art of knowing exactly what you want men to do and seeing that they do it in the best and cheapest way - **F.W. Taylor.**

13. To manage is to forecast and plan, to organise, to command, to co-ordinate and to control **Henri Fayol.**

14. Management is the coordination of all resources through the process of planning, organising, directing and controlling in order to attain stated goals - **Henry L. Sisk.**

15. Management is a social process entailing responsibility for the effective planning and regulation of the operations of an enterprise **E.F.L. Brech.**

16. Management consists of all organisational activities that involve goal formation and accomplishment, performance appraisal and the development of an operating philosophy that ensures the organisation's survival within the social system - **W.J. Duncan**.

17. Management is the creation and maintenance of an internal environment in an enterprise where individuals, working in groups, cart perform efficiently and effectively toward the attainment of group goals - **Koontz and O'Donnell.**

18. Management is a distinct process consisting of planning, organising, actuating and controlling, performed to determine and accomplish the objectives by the use of people and resources **George R. Terry.**

19. It may be defined as a technique by means of which the purposes and objectives of a particular human group are determined, clarified and effectuated - **Peterson and Plowman.**

20. It may be defined as the art of securing the maximum results with the minimum of effort so as to secure maximum prosperity and happiness for both the employer and the employee and give the public the best possible service - **John F. Mee.**

21. Management is simply the process of decisionmaking and control over the action of human, beings for the express purpose of attaining 'predetermined goals - **Stanley Vance.**

Nature (Characteristics) of Management :

1 **It is a group of people and function both :** Management is a group of people with different levels depending on responsibility and it is a group of functions (process elements) like planning, organising, staffing, directing, controlling, reporting, budgeting, motivating, coordinating etc.

2 **It is universal :** Whether it be a family, office, club, army, school, trade, industry or business, management is required every-where.- t*s fundamental principles are applicable in all areas of organised activity.

3. **It is an Art & Science both :** As it requires knowledge, skill, creativity etc., it is an art. As it requires universal application of principles for definite results and systematic knowledge, mathematics and use of scientific rules or study, it is a science also.

4. **It is an executive function :** It is a technique by which the objectives are predetermined and obtained by methods required.

5. **It is purposeful :** Management without objectives is meaningless. It is creative, decides goals and try to achieve them. Therefore, it is purposeful.

6. **It is dynamic :** because it changes with time, need, objectives and challenges of business to be successful at all times. It cannot be static.

7. **It is intangible :** because the process of management is invisible though the managers are visible.

8. **It is leadership :** Manager acts as a leader of the groups, creates environment for followers and gets work done through them. Therefore, it is a leadership function.

9. **It is decision-making :** All managers have to take decisions with utmost care using data and analysis to obtain results. Without decision, management is not possible.

10. **Co-ordination as unifying force :** The essence of management lies in co-ordinating all its efforts into a team. It requires harmony instead of conflicts. It integrates human and other resources.

11. **It is a practice & profession both :** Managers are made and not born. They learn by practice. The whole management process is practice to acquire goals. Only after training, skill and experience, it can become a profession like management consultancy.

12. **It is a social process :** Management is by people, through people and for people. Human factor is most important. After all everything is for human beings. Therefore, it is a social process.

13. **It is situational or contingency :** because decisions are dependable on situations which are changeable.

14. **It is multidisciplinary :** It derives knowledge from several disciplines like engineering, science, economics, mathematics, psychology, sociology etc.

15. **It is a continuous process :** It is an on-going process continuing to operate till achievement of goals.

16. **It strives for organisational goals :** If there is no management, there may be conflict between individual (personal) goals and organisational goals. Management has to work for organisational goals (objectives).

Importance (Significance) of Management:

1. It is a key to economic success of nations, organisations and all group activities.
2. It accelerates the process of development and cuts its cost.
3. It accelerates capital formation and progress.
4. As Peter Drucker 'says 'Only superior management, competence and continuously improved management performance can keep us progressing, can prevent our becoming smug, self-satisfied and lazy.

4. ELEMENTS OF MANAGEMENT FUNCTIONS

All above criteria conclude seven basic elements or functions of management as follows:

1. Setting up the **objectives** well defined.
2. **Planning** the course of action to be taken to attain above objectives.
3. **Organising** the structure of staff and assigning specific responsibilities to different individuals (members, workers) i.e. delegation and decentralisation of power and authority.
4. **Directing** and **Co-ordinating** the efforts of all members working for the organisation.
5. **Controlling** the activities of the members through setting up standards for performance. It includes monitoring and evaluating that the objectives are achieved and follow up for those to be achieved.
6. **Motivating** the members to cooperate with each other for the achievement of the objectives
7. **Innovating** to improve the objectives for the future.

See Figure 6.1 and 6.2.

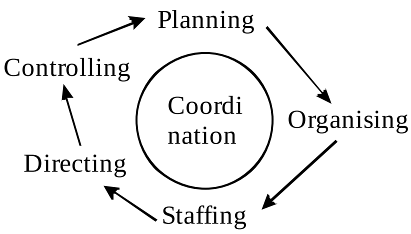

Fig. 6.1 Elements of Management Process

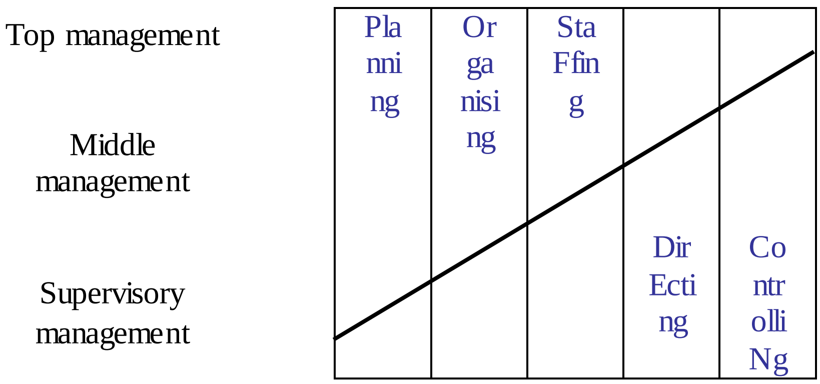

Fig. 6.2 Managerial Functions at different Levels

Fig. 1 Explains inter relationship of basic elements of management process and Fig. 2 shows their proportion at different levels.

The terms management, organisation and administration are used side by side. The term 'administration' is used to refer to the activities at the higher levels of the management, such as Government administration is the higher management for the largest section (people). The term 'organisation' is generally used for the structure of responsibilities and relationship attached to the executive and supervisory posts.

The words **direction, superintendence and supervision** are also used side by side to include determination of objectives and policy and to exercise overall control over the affairs of an enterprise, directing subordinates, motivating and leading them, communicating, getting employees to accomplish and overseeing their tasks.

Administration is that part of the management which lays down the objects, policies, programmes and procedures for which the organisation and its management strive and operate to accomplish the predetermined objectives.

Organisation is that part of the management which lays down the structure of responsibilities to distribute activities or functions among the managerial, supervisory and specialist personnel and the interrelationship among them.

Thus, administration can be said 'brain' or 'mind' and its function is 'thinking'. The organisation is 'head' and 'body' and its function is 'doing'. The management is 'eyes' and its function is 'seeing' that the things are done (by the organisation) as thought (by the administration). All the three are the organs of one body or entity.

Management are of many types such as factory management, business management, safety management, materials management, project management etc.

The materials management is defined as the function responsible for the co-ordination of planning, sourcing, purchasing, moving, storing and controlling materials in anoptimum manner so as to provide a pre-decided service to the customer at a minimum cost

5. MANAGEMENT PRINCIPLES

5.1 General Principles of Management:

According to Joseph L.Massie, general principles are 'approximations of generalisations from experience'. These principles are short statements for guidance and practice and not the rules or regulations. They are not rigid. They may change with change in conditions. They have been developed in course of time and may further develop from new experiences.

According to George Terry 'by means of principles of management, a manager can avoid fundamental mistakes in his job and foretell the results of his actions with confidence'.

According to Harold Koontz, these principles help managers to (i) improve efficiency (ii) increase knowledge (iii) impart training (iv) improve research and (v) attain social goals.

The nature of management principles is characterised by its feature of universality, dynamic, relative and human nature.

Henry Fayol has listed following 14 principles of management:

1. **Division of work** - Work of every person should be limited to a single leading function to do more and better work with the same effort.

2. **Authority and Responsibility** - They go hand in hand. Authority is the right to give orders and power to exact obedience. Responsibility arises when authority is given. Responsibility implies an obligation to perform duty (task) in a satisfactory manner. Official authority is derived from position one holds while personal authority is derived front intelligence, experience and knowledge one holds.

3. **Discipline** - It is the obedience to agreement between members and must prevail throughout an organisation for its smooth functioning. Clear understanding between workers and management regarding their rules, regulations, orders and penalties is necessary.

4. **Unity of Command** - Every employee should receive orders from one superior only. Dual command is a source of conflict or confusion. One group of workers should work under one supervisor only.

5. **Unity of Direction** - There should be one head and one plan for a group of activities having the same objective to ensure unity and co-ordination in management.

6. **Subordination of individual to general interests** - Employee's personal interest should not dominate the general i.e. management's interest. In case of conflict between such interests, personal interests should be sacrificed.

7. **Remuneration of personnel** -The amount and methods of payment should be just, fair and satisfactory to both employees and employers.

8. **Centralisation** - To decrease subordinates' role is centralization and to increase it is decentralisation. This principle should be introduced to yield the best results considering individual circumstances.

9. **Scalar Chain** - Normally a chain of authority runs from the highest authority to the lowest rank, but however if it is very long and causes delay, cross-communication (shortcut) between two employees at lower level should be permitted to avoid such delay (Gang-Plank principle).

10. **Order** - There should be proper arrangement of men and materials in required order. As there should be a place for everything and everything should be in its proper place, there should be an appointed (clear) place for everyone and everyone should be in his/her appointed place. This kind of order requires precise knowledge of human requirements and resources of the concern to maintain balance between them.

11. **Equity** - There should be equality, justice, kindness and impartiality in treatment to employees and a sympathetic and unbiased attitude toward them. This generates better industrial relations.

12. **Stability of tenure of personnel** - Provide job security and long-term service to reduce labour turnover. Instability hampers interest, motivation and efficiency of employees.

13 **Initiative -** This refers to freedom to think and take decision. Employees should be given an opportunity to take initiative to formulate and execute plans even though some mistakes may result. When employees are given freedom to work independently they tend to grow and develop.

14 **Esprit de corps** - Instead of 'divide and rule' management should strive to install team spirit, co-operation and harmony among workers to make the management united and powerful.

These principles are to be practised for safety management also.

5.2 Managerial Role, Authority, Responsibility and Power :

Managerial Roles :

Mintzberg describes following ten roles for managers:

I. Interpersonal Roles:

1 **Figurehead -** acts as head, performs legal and social duties e.g. greets a special visitor, takes customer to lunch/attends ceremony etc.

2 **Leader** - responsible for work unit e.g. hiring, firing, motivating, training, staffing.

3 **Liaison** - maintains outside contacts to get favours, feedback, follow up, information etc. e.g. meeting a peer in another department, contacting Government Official etc.

II. Information Roles :

4 **Monitor** - seeks and receives information on progress, performance, environment etc., e.g. asking reports.

5 **Disseminator -** passes information e.g. gives workers important date, briefs higher executives.

6 **Spokesman -** sends information outside e.g. represents company in meeting, replies on behalf of company.

III. Decisional Roles :

7 **Entrepreneur -** improver of the work unit e.g. looks out for new ideas, develops new programmes.

8 **Disturbance handler** - responds to pressure, crisis etc. e.g. faces strike, decides how to tackle emergency, failure of supply of money, material, services etc.

9 **Resource allocator** - allocates resources of men, money, material, market, machines, methods etc. e.g. sets budget priorities, selects good proposals.

10 **Negotiator** - represents management in settlement, agreement, bargaining, negotiating, hearing grievances and giving opinion etc. e.g. negotiating union demands.

Authority:

Authority means legal or delegated power or right to a person. Government officials have powers vested in them by law and therefore they are called 'Government authorities'. Similarly when a manager is given powers to perform his managerial roles, by the higher executive, board or the owner, it is said that he has authority to act, sign etc. e.g. Safety Officer has authority to design or sign safety work permit or to sign a purchase order of safety equipment.

Authority can be delegated also. It is decentralisation of power downward. A safety officer can delegates his authority to permit some work to safety supervisors.

Authority gives right to a manager, and disobedience of his order injures his right for which a penalty is possible. The statements of authority are called ''authoritative' which may set an example. It has force of implementation.

Definitions :

1. **Henry Fayol -** Authority is the right to give orders and the power to exact obedience.

2. **Koontz and O'Donnell -** Applied to the managerial job, authority is the power to command others to act or not to act in a manner deemed by the possessor of the authority to further enterprise or departmental purpose.

3. **Herbert Simon -** It is the power to make decisions which guide actions of others.

4. **Terry -** Authority is exercised by making decisions and seeing that they are carried out.

Characteristics:

Thus, characteristics of authority are

1. It is attached with position, is legal, legitimate and formal.
2. It gives power to superior i.e. right to act, control, command subordinates and to achieve goals.
3. A subordinate obeys the superior by virtue of his authority.
4. It is not unlimited, its extent and limits are defined in advance.
5. It is a relationship between two individuals - a superior and his subordinate.
6. It is used to achieve organisational (not personal) goals.
7. It is a key to the managerial functions.
8. It gives right of decision making and to get the decisions carried out.
9. It can be delegated.
10. It is objective, though its existence is subjective.

Theory:

Theories for the sources of authority are
1. Formal authority theory.
2. Acceptance authority theory.
3. Competence authority theory.

Scope:

Its scope or limitations are
1. Biological limitations.
2. Physical limitations.

3. Legal constraints.
4. Social constraints.
5. Economic constraints.
6. Limited span.
7. Organisational limitations.

Responsibility:

Authority brings responsibility. When authority is given to a manager, he possesses responsibility i.e. accountability and is answerable for all works, acts and functions for which authority was given to him. When a safety officer is authorised for all safety functions, he becomes responsible i.e. liable to give explanation for the success or failure of all his decisions, works, functions etc. Safety Officer is responsible for accident prevention work. When supervisor allows working on unguarded machine and accident takes place, he is responsible for this work of his omission or negligence. When responsibility is given to us, we must strive to fulfil it by all our sincere efforts and care.

A concept of responsible care' is developed to run our plant with utmost care toward surrounding society. Breach of responsibility attracts penalty.

Definitions :

1. **M. E. Hurely -** Responsibility is duty to which a person is bound by reason of his status or task. Such responsibility implies compliance with directives of the person making initial delegation.

2. **Koontz and O'Donnell -** Responsibility is the obligation of a subordinate to whom duty has been assigned to perform the duty.

3. **R. C. Davis** - Responsibility is the obligation of an individual to perform assigned duties to the best of his ability under the direction of his executive leader.

4. **Dalton McFarland** - Responsibility is the duties and activities assigned to a position or to an executive.

5. **Theo Haimann** - Responsibility is the obligation of a subordinate to perform the duty as required by his superior.

Characteristics:

Main characteristics of responsibility are

1. It cannot exist without authority and vice versa.
2. It originates from superior-subordinate relationship.
3. It is absolute and cannot be delegated. The authority can be delegated.
4. He who holds (accepts) responsibility, is accountable to his superior.
5. It is an obligation of a subordinate to perform the duty assigned to him.
6. It is a derivative of authority.
7. It flows upward while authority flows downward.
8. Accountability arises out of responsibility and they go together. Authority gives responsibility which, in turn, creates accountability.

Power :

Power means ability or capacity to do something, to act, to control, to exercise force or command etc. Power also comes with authority because authority gives right and that right gives power. Powerless person cannot do anything. Manager without power cannot manage things, subordinates do not follow his orders and goals of management can never be achieved. Therefore, power should be vested by giving authority to manager. In case of doubt or ambiguity, powers are to be assumed by the manager to get the work done. Power is to be exercised with due care and reasonable requirement. Undue use of power may create opposition.

A manager's power may be measured in term of his ability to give order or reward, punish individuals, withdraw order or reward etc. Power is an important means to enforce obedience to the rules, regulations and decisions of the organisation. Its use (exercise) may affect the behaviour of people. Distinction between authority and power can be explained as under :

No.	Authority	Power
1	Right to do or command.	Ability to do or command.
2	Derived from position in organisation or institution.	Derived from many sources like authority, seniority, knowledge, competence etc.
3	Flows downward – can be delegated.	Flows in all direction – cannot be delegated.
4	Legitimate – resides in the position.	May be illegitimate, extra constitutional or assumed.
5	Increases as one goes up in hierarchy.	May or may not accompany increase in authority.
6	Right to allocate resources.	Ability to control resources.
7	Narrow term- one source or subset of power.	Broad concept – can achieve result when authority fails.
8	Visible from organisation chart. It is institutionalized power.	Not visible from organisation chart.

Thus, authority, responsibility and power go side by side and are useful tools for managers to achieve the organisational goals.

5.3 Span of Management :

The span of management refers to the number of subordinates a manager or supervisor can supervise effectively because of his limitations of time, capacity, ability, nature of work, pressure of work etc. No single individual can effectively supervise unlimited number of subordinates. The terms span of management, span of control, span of supervision, span of authority are used interchangeably in management literature.

V.A. Graicunas, a French management consultant has given following formulae for different relationships due to span as under : Direct single relationships = n

(n = No. of subordinates)

Direct group relationships = $n (2_n / 2-1)$
Cross relationships = $n (n- 1)$
Total relationships = $2_n/2\ n (\quad +n-1)$

This formula gives some figures as under :

No. of Subordinates	Total Relationships

1	1
2	6
3	18
4	44
5	100
10	5210
18	2359602

Black and Scott have given another formula as $S = L\sqrt{n}$ where S = Span of Control, L = No. of Supervisory levels and n = No. of Employees.

Thus, if there are 125 employees and 3 levels of supervision, average span of control would be :

$$S = 3\sqrt{125} = 5$$

This is an average (general) indicator and it ignores details. Care is required in interpretation.

Modern approach discards such magic formulae and contends that span is flexible and there is no single (fixed) span for all situations. It depends on many factors as under :-

Factors determining Span of Management :

They are

1. Nature of work.
2. Type of technology.
3. Ability of the manager.
4. Capacity of subordinates.
5. Degree of decentralisation.
6. Planning.
7. Staff assistance.
8. Communication techniques.
9. Time available for supervisors and
10. Geographical distance of subordinates.

Narrow (tall) & Wide (flat) Span :

Narrow span means a few subordinates and wide span means more subordinates directly under one manager or supervisor. See Fig 6.3 & 6.4.

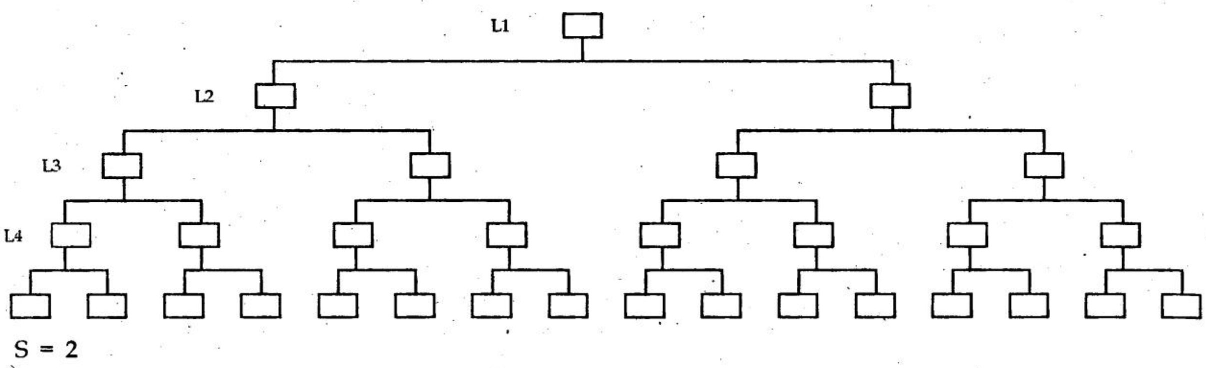

Fig 6.3 Narrow or Tall Structure, Span = 2, Level=4

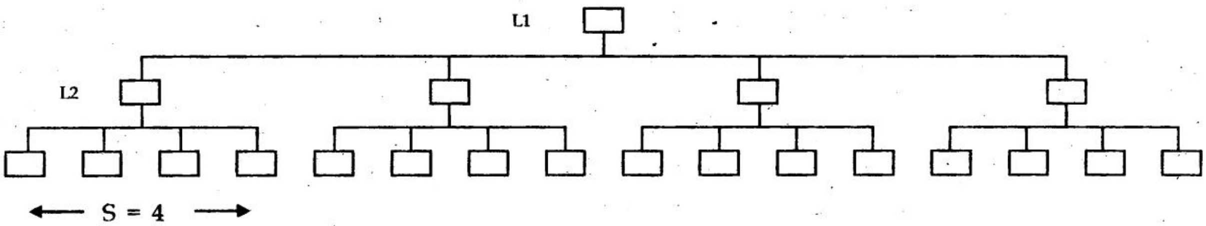

Fig 6.4 Wide or Flat Structure, Span = 4 Level = 2

Now a day a tendency toward wide span of management is increasing because of (1) the trend of decentralization (2) increasing size of organisation (3) need for quick decision making (4) faster communicant techniques and (5) growing acceptance of group processes and new patterns of leadership.

Difference between tall and flat structure is as follows :

No.	Tall (narrow) Structure	Flat (wide) Structure
1	Centralisation and close control.	Decentralistaion and loose control.
2	Better coordination due to inter-locking network.	Difficulty in co-ordination.
3	Less mistakes due to close super-vision.	More mistakes due to loose supervision.
4	Good for staff desiring detailed guidance.	Good for staff requiring independence, challenge and responsibility.
5	Distorted and delayed communication.	Speedy and improved communication.
6	Costly because of overheads.	Less supervisors and less overheads.
7	Slow decision making.	Faster decision making.
8	Greater distance between top and bottom.	Lesser administrative distance.
9	Less pressure on managers	High pressure on managers.
10	Less opportunity for development of subordinates.	More such opportunity.
11	Less competent subordinates can be employed.	Competent and willing subordinates are required.

5.4 Delegation and Decentralisation of Authority :

(A) Delegation of Authority :

Definitions :

1. **F.G. Moore –** Delegation means assigning work to others and giving them authority to do it.

2. **Koontz & O'Donnell –** Authority is delegated when decision making power is vested in a subordinate by superior.

3. **Koontz & Cyril O-Donnell –** The entire process of delegation involves the determination of results expected, assignment of tasks, delegation of authority for accomplishment of these tasks and exaction of responsibility for their accomplishment

4. **Dr. Terry -** Delegation means conferring authority from one executive or organisation unit to another in order to accomplish particular assignments.

5. **Louis A.** Alien -It is a process a manager follows in dividing the work assigned to him so that he performs that part which only he, because of his unique organisational placement, can perform effectively and so that he can get others to help him with what remains.

   Allen says "once a man's job grows beyond his personal capacity, his success lies in his ability to multiply himself through other people" (i.e. delegate his work to others).

6. O. **Jeff. Herris** - Delegation of authority is the delivery by one individual to another of the right to act, to make decision, to requisition resources and to perform other tasks in order to fulfil job responsibilities.

7 **E.F.L. Breach -** Delegation means the passing on to others of a share in the four elements of the management process, that is to say, in the command of the activities of other people and in the responsibility for the decision making that will determine the planning, co-ordination and control of the activities of such other people.

Thus, delegation means assigning work to others and giving them authority to do it. It gives right to decision making in certain defined areas and charging subordinates with responsibilities for carrying Out those assigned tasks.

Characteristics:

1. A superior grant some authority to a subordinate who must act within the limit prescribed.
2. Entire authority cannot be delegated.
3. Responsibility cannot be delegated. No manager can escape from his obligation by delegating it authority to subordinates.
4. Delegation does not reduce the authority of a manager. It is retained even after delegation. Manager can reduce, alter, enhance or take back the delegated authority.
5. Delegation may be specific or general, written or oral, formal or informal. It does not mean i avoiding decisions or abandonment of work.
6. It is an art because it is creative, practice based, involves personal skills, result oriented and b personalised process.

Importance of Delegation:

1. Human capacity is limited. By delegation, a manager can distribute his workload to others and he can concentrate on more important policy matters.
2. It facilitates quick decisions because the authority to decide lies near the point of action. Subordinate can decide easily and quickly.
3. It enables to obtain specialised knowledge and expertise of subordinates.
4. It improves job satisfaction, motivation and morale of subordinates. It satisfies their needs of recognition, responsibility and freedom. It prepares a second line of command which is always useful.
5. It increases interaction, understanding and healthy relationship with subordinates. It binds group members together.

6. It is an aid to executive development. It facilitates expansion and diversification of business through a team of competent and experienced workers.

Process (Elements) of Delegation : It involves four steps (1) Results are defined before delegation (2) Assignment of duties (3) Granting of authority and (4) Creating accountability for performance.

Degree of delegation is classified as over-delegation or under-delegation.

Obstacles of delegations are reluctance to delegate (by managers), reluctance to accept delegation (by subordinates) or if both are ready there are organisational weaknesses like inadequate planning, splintered authority, lack of unity of command, absence of control techniques, non-availability of competent persons, unclear authority, internal distrust etc.

Principles of Delegation:

1. Define functions (job, target, results) before delegation.
2. Delegate authority and power necessary.
3. Parity (balance) of authority and responsibility should be maintained.
4. Responsibility cannot be delegated.
5. Unity of command i.e. a subordinate should be responsible to one superior only.
6. Limits of authority of each subordinate should be well defined.
7. Authority level principle i.e. each subordinate should take decision within his jurisdiction only and matters beyond his scope of authority should be referred to superior.
8. Scalar principle i.e. chain of authority should go without break from top to bottom in organisation structure. Each employee should be aware of the source from which authority and command flow up to him and to whom he should report his work .and difficulties.

(B) Decentralisation of Authority':

Definitions:

1. **Henry Fayol** - Everything that goes to increase the importance of subordinates' role is decentralisation, everything which goes to reduce it, is centralisation.

2. **Joseph Meassie** - Decentralisation is an organisational concept which takes decision making to the lower levels of organisation.

3. **Newman, Summer and Warren-** It is nothing but distribution of managerial functions and assignment of definite responsibilities to various managerial units.

4. **Keith Davis** - Dispersal of authority and duties to the lowest unit in the organisation so far as it is feasible is called decentralisation.

5. **E.E.L. Breach** - It is the pattern of responsibility arising from delegation.
6. **Earnest Dale -** It is the delegation of business decisions by the owners to their immediate representatives and then to others further down in the management hierarchy.

7. **Louis A. Alien-** It is the systematic effort to delegate to the lowest levels all authority except that which can be exercised at central points.

Decentralisation is associated with fundamental principle of democratic management. Centralisation and decentralisation are relative and opposite terms. Neither 100% centralisation nor decentralisation is desired or possible. Proper balance between them is required depending on nature and span of the management.

Difference between Delegation & Decentralisation:

No.	Delegation	Decentralisation
1	It is a technique of management.	It is a philosophy of management.
2	Relationship between superior & subordinate.	Relationship between top management and other department or divisions.
3	It is essential and useful.	It is optional. Management may or may not disperse authority.
4	Person who delegates, holds control over subordinates.	Control is delegated to departmental heads.
5	It is a process or an act.	It is the end result of delegation.
6	Delegation is possible without decentralisation.	Decentralisation of not possible without delegation.

Advantages & Disadvantages of Decentralisation :

No.	Advantages	Disadvantages
1	Relief a top executives.	Difficulties of co-orindate.
2	Motivation of subordinates.	Expensive (staff cost).
3	Executive development.	Problems of control.
4	Quick decisions.	Internal constraints.
5	Effective communication.	External constraints e.g. market, unionism, Govt. policy.
6	Efficient supervision and control.	Harmful in emergency.
7	Growth & diversification.	Loss in staff service.
8	Development of initiative and responsibility.	Lack of uniformity.
9	Boosts morale.	Narrow product lines.
10	Simplifies division of work.	Pressure increases on departmental heads.
11	Development of leadership.	Importance and effect of superior are decreased.
12	Stability and continuity.	
13	Flexibility.	
14	Develops harmony.	
15	Preserves grip on market.	

Degree of Decentralisation : Earnest Dale has given four tests to measure degree of decentralisation-

1. Number of decisions.
2. Importance of -decisions.
3. Effects of decisions.
4. Checking of decisions.

Effective Decentralisation : This requires

1. Proper balance between centralisation & decentralisation.
2. Centralised authority to decide proper decentralisation, co-ordination and to resolve its problems.
3. Good number of competent managers.
4. Effective and speedy communication.
5. Adequate controls to distribute resources, assign costs, lay down standards and norms.
6. Willingness of the top management to share authority downward.

Factors determining Decentralisation : They are-

1. Size and complexity of the organisation.
2. History of the organisation.
3. Nature of functions.
4. Scattered operations of production, sale etc.
5. Planning and control procedures.
6. Degree of diversification.
7. Complexities of the situation.
8. Availability of competent personnel.
9. Communication system and
10. Outlook of the top management

6 SAFETY MANAGEMENT AND ITS RESPONSIBILITIES

6.1 Safety Management Defined :

We have seen the definitions of management in the foregoing Part 3 Based on this, we can define the safety management as The accomplishment of safety objectives by first establishing the safety objectives and then by attaining them through the process of planning, organising, staffing, directing and controlling i.e. motivating and co-ordinating all efforts to attain those objectives and also innovating to improve them for the future.

Safety organisation (higher level management) ;can also be defined as a definite, planned and organised set up whose purpose is to enlist and maintain the combined efforts of organised personnel for the purpose of total loss control including accidents and environmental protection in an industry or establishment.

In a small unit where there is no safety officer or department or group of persons for safety activity, even a single person - supervisor, occupier or Worker-should assume the duty of safety management.

6.2 Place of Industry in Society and Safety in Industry :

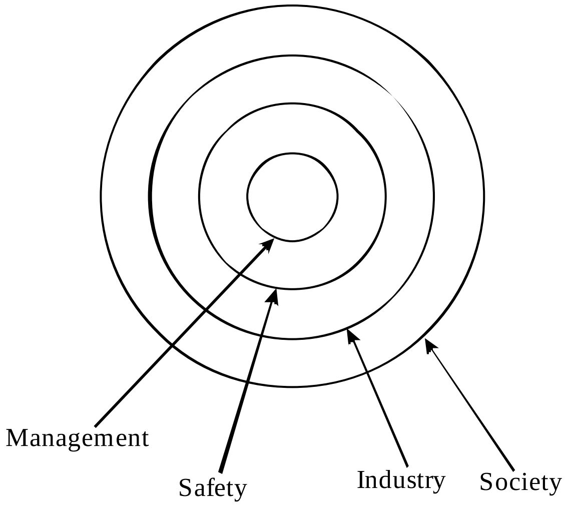

Fig. 6.5 Place of Safety Management

Industries are inevitable in modern society because human needs of foods, clothes, homes, amenities, luxuries, services and knowledge are to be fulfilled. It is also required for employment. Wants of modern society are day by day increasing with the increase in population, invention, technology, industrialisation and human desires. How to produce, distribute and supply all such wants to the whole humanity? Mass production is possible by industries only. Distribution and supply are possible by trade and business. Therefore place of industry is ahead, vital and most desirable. We cannot eliminate industry from society. Only its hazards are to be eliminated and for this purpose, the safety management is desired. As place of industry in society is inevitable, similarly the place of safety in industry is also inevitable, because safety is -most required in industries.

Industrialisation has been defined by Dr. Luigi Parmeggiani as "the process of change in the mode of production to utilise more capital per unit of output, higher levels of technology and management, widening markets with cost economics of scale and specialised location of plant, type .of plant and skills".

Industrialised country has been defined as one that derives more than 30% of its gross domestic product (GDP) from manufacturing, while a semi industrialised country derives 20 to 30%, an industrialising country between 10 to 19% and a non-industrial country less than 10% from the same source.

Accident problem created by the industrialisation is already discussed in Chapter - 1 & 5. Increasing number of accidents and their costs with rapid Industrialisation call for accident prevention work. This is an essential task for every management. Occupational hazards, accidents and diseases, are to be prevented by providing protection to men and machines, by good maintenance, medical health checkups, good working and living conditions, prompt and effective legislation and last but not the least by constant education, training and motivation of workers to work safely. Thus, a place of safety in industry must be accepted and strengthened by providing efficient safety management.

6.3 Safety Management's Role :

This is a manyfold role as described in eleven heads as under -

6.3.1 General and Scientific Functions :

The basic safety role of any industrial management is well derived from the five steps of accident prevention suggested by H.W. Heinrich. These are organisation, facts finding, analysis of the facts found, selection of remedy and application of the remedy..

The Scientific Method of Management considers more productive or improved method of management by careful and accurate classification of facts, their sequence and correlation, discovery of scientific laws and its impartial application, new concepts, experiments and observations. The six functions of scientific safety management are:

1. **Planning :** It includes setting safety objectives, formulating safety policy, safety programming, budgeting and determining safe or standard procedures. Good planting at the design stage always helps. Planning for site, effluent disposal, facilities for storing and handling raw materials, intermediates and products, types of floor, roof, construction, lighting, ventilation, layout of machinery, pressure vessels, lifting machines, hazardous processes, boilers, storage tanks, repair services, auxiliaries, utilities, fire protection, training, welfare and sanitary facilities etc., must consider safety points at this initial stage so that the planning and design defects can be eliminated or minimised from the beginning. Previous plans approval and correction after operation are also necessary.

2. **Organising :** It includes establishment of the formal structure of authority through which work subdivisions are defined, arranged, and co-ordinated for the planned safety objectives.

An organisational set-up describes four classes of management - Top or Executive, Intermediate, Middle and Supervisory management. The set-up may vary according to the size and nature of establishment. A model safety organisation is shown in Fig 6.6.

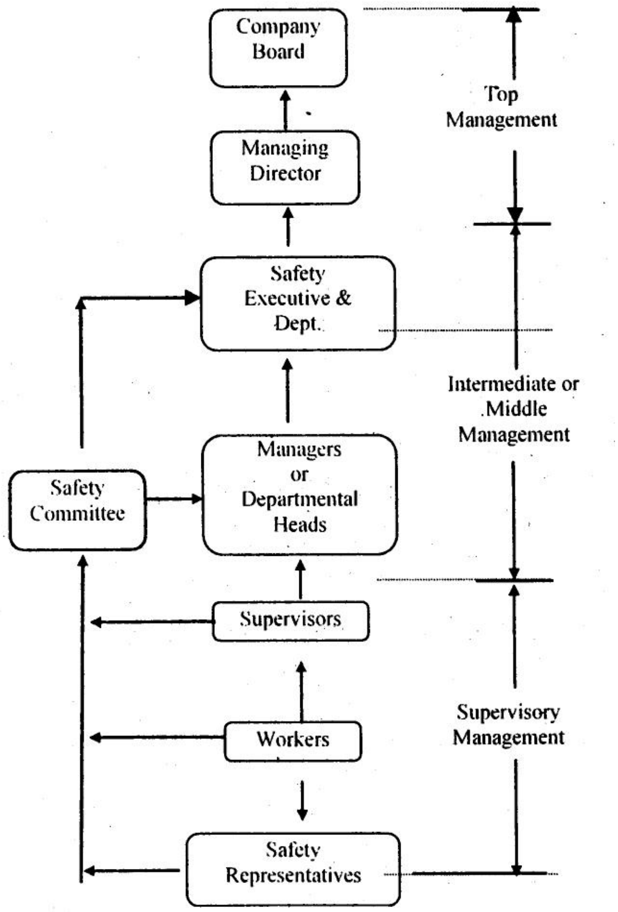

Fig. 6.6 Organisational Set-up (Structure)

The Company Board decides the safety policy and objectives and monitors its implementation. Managing Director is reportable to the Board for implementation of safety policy. Safety executive or safety department reports to MD. Managers are answerable to the Safety Department or Executive for application of the safety arrangements. Supervisors are reportable to the Managers for shop floor extension and application of safety policy, rules and procedures. Workers are responsible to their supervisors for effectively carrying out the safety rules and precautions. Safety Representatives selected from workers and supervisors advise and assist to Safety Committee for promoting health and safety. Safety Committee advises on all matters of safety and health to the Managers and the Managing Director.

3. **Staffing :** It includes personnel function of recruitment and training the staff and maintaining safe and favourable conditions of work through personnel.

4. **Directing :** It is a continuous task of taking decisions, ordering, instructing, guiding and advising on all maters of safety.

5. **Controlling :** It includes performing, evaluating and correcting the performance according to objectives, procedures and plans. It is concerned with quality, times, uses and cost in safety matters.

6. **Co-ordinating :** It includes interrelating and synchronising the different activities for achieving safety goals.

Let us see these functions one by one -

6.3.2 Planning for Safety :

Planning is the most fundamental and the first function or element of management process. Other functions rest on it- Need for planning is increasing because of changes in technology, materials, methods, processes, demands, law, government policy, procedure and competition.

Definitions of General Planning :

1. **Henry Fayol** - Planning refers to a preview of future activities.

2. **UrWick** - It is fundamentally a mental predisposition to do things in an orderly way, to think before acting and to act in the light of facts rather than of guesses.

3. **Haynes & Massie** - Planning is that function of manager in which he decides in advance what he will do. It is a decision making process of a special kind, its essence is futurity.

4. **Koontz and O'Donnell** -It is an intellectual process, a conscious determination of course of action, the basing of decisions on purpose, facts and considered estimates.

5. **George R. Terry** - Planning is the selecting and relating of facts and using of assumptions regarding the future in the visualisation of formulation of proposed activities believed necessary to achieve desired goals.

6. **Dalton McFarland -** It is defined as the activity by which managers analyse present conditions to determine ways of reaching a desired future stage. It embodies the skills of anticipation, influencing and controlling the nature and direction of change.

7. **Theo Haimann** - Planning is the function that determines in advance what should be done. It consists of selecting the enterprise objectives, policies, programmes, procedures and other means of achieving these objectives.

Planning is a process, as explained by above tinkers, and a 'plan' is the outcome of this process.

'Safety Planning' defined : From above general definitions, we can define safety planning as the first step of safety management wherein a safety manager decides in advance safety objectives, policy, procedure, strategies, rules, programmes, methods, budgets, schedules and necessary means for achieving these objectives, considering facts (of accidents and other hazards) and anticipating foreseeable events that may affect safety of plant, people and environment.

Purpose (importance) of General Planning : Purpose, importance, significance, advantages or utility of planning are summarised as under –

1. Focuses on. objectives and results.
2. Activities become purposeful and orderly.
3. Reduces uncertainly, risk, wastage etc.
4. Helps in controlling future events (loss).
5. Helps in saving of costs.
6. Imparts accuracy.
7. Helps other functions of management i.e. organising, staffing, budgeting, directing, controlling etc.
8. Provides direction.
9. Creates healthy organisational climate.
10. Provides framework.
11. Helps to visualise a clear and complete picture of the business or activity.
12. Secures co-operation from employees.
13. Maintains balance between various activities.
14. Encourages innovation and creativity.
15. Guides decision making.
16. Provides basis for decentralisation.
17. Provides efficiency in operations.

Purpose (Areas) of Safety Planning : It includes all above 17 aspects with reference to health and safety of workers and public, safety of plant and surrounding environment, and prevention of total losses. Some subjects of safety planning are given below.

1. To draft health and safety policy and environmental policy for the management.
2. To decide safety committee, its objectives and effective functioning.
3. To decide safety targets like zero/minimum accidents, maximum working hours without accident, safety education, training and awareness programmes for the workers and the public.
4. Areas of hazards and their detection, inspection, audit, risk assessment and measures for their removal or minimisation.
5. Accidents investigation, analysis, costs calculation and introducing safety measures to prevent their recurrence.
6. Organisation structure, staff, key persons and their roles for safety.
7. Standards for safety equipment, tools, permissible exposures etc.
8. Preparation, rehearsal and updating of on-site emergency plans.
9. Details of safe or standard operating procedures (SOP), close-down procedures, methods, fire fighting procedures, emergency preparedness, first-aid etc.
10. Testing, inspection and records of lifting machines, pressure vessels, ventilation, lighting, safe environment etc., as per statutory need.

11. Medical examination of workers, records and corrective action as directed by doctors.
12. Compliance of statutory and non-statutory safety provisions, their records and reporting.
13. Search for safe and clean technology for the process and hazard control techniques for detection and removal of all hidden hazards.
14. Follow-up action, evaluation of safety programmes and improvement of future plans, strategies etc.
15. Planning to achieve national and international standards, awards etc.

Nature of Planning : Nature, features or characteristics of planning are as under

1. It is a primary and most important function of management.
2. It is goal oriented.
3. It is an intellectual or rational process.
4. It is pervasive, it encompasses all levels of management.
5. It is a continuous process (function).
6. It is conscious activity.
7. It is flexible.
8. Forecasting or forward looking is the essence of planning.
9. Accuracy is essential to planning.
10. It is a choice of alternatives.
11. It is concerned with group objectives.
12. It is an integrated process.
13. It is directed towards efficiency and achievement of decided goals.

Factors (Limitations / Constraints) affecting scope of Planning : They are :

1. Inaccuracy.
2. Time consumption.
3. Rigidity.
4. Cost.
5. Attitudes of management.
6. Faults in planning system i.e. lack of reward, lack of participation or specific activities and incompetence of the planner.
7. Lack of orientation and training for managers.
8. Uncertainty.
9. Resistance to change.
10. False sense of security.
11. Environmental constraints i.e. technological, social, legal, economic and other outside forces.

Effective Planning:

According to Gray Dessler, managers should consider following points to plan effectively.

1. Develop accurate forecasts.
2. Gain acceptance for the plan.
3. Plan must be sound one.
4. Develop effective planning organisation.
5. Be objective.
6. Measure firm's market value.
7. Decide in advance the criteria for abandoning a project.
8. Set up a monitoring system.
9. Revise long-term plans every year.
10. Fit the plan to the situation.

Plans should be simple, easy to understand, clear to followers, selective, thorough, based on well defined objectives, flexible to adopt changes, balanced, comprehensive, economical, practical and should provide standards for evaluation procedure and, proper analysis and classification of actions.

Procedure (steps) of Planning : Basic steps in planning are as under

1. Identify problems.
2. Establish objectives (goals).
3. Develop 'planning premises' (e.g. land, labour, capital, market, money, time, production, public relation, employee relation, reputation, morals, policy, programmes, rules, emergencies, new inventions, population trends, supply position; economic, technological, political and social conditions etc.)
4. Determine alternative courses of action.
5. Evaluate the alternatives.
6. Select a course of action.
7. Formulate derivative (final) plan and sub-plans as per need.

These procedural steps are to be applied in planning for safety. Here planning premises for safety would be safely objectives, safety standards, safety procedures, safety rules, safety provisions, safety training, safety programmes, safety policy, committee, inspection, audit, analysis, assessment, accident analysis, other control methods, forecasting of emergencies and planning for that, development of new methods, purchase policy, safety equipment, safety reports & records, use of new material, process or technology, process revision and various subjects of safety including fire, explosion, toxic exposure etc.

A safety manager requires wide knowledge and help of other departmental heads, consultants, experts etc., while planning on above specialised areas.

Range of Planning : Based on time schedules three types of plans can be prepared as under-

1 **Short-term (operational) plans** - For a period up to one year. They are specific and detailed and cover forms and contents of long term plan. They are prepared on the basis of strategic and tactical plans. Examples are daily operations, repairs and maintenance plan, purchase plan, product plan, activity planning, working methods, procedure, accident investigation & analysis, inspection techniques, induction training etc.

2 **Medium-term (intermediate) plans** - For a period of more than one year and less than 5 years. They are co-ordinative and tactical in nature. They are less detailed than short-term plan. Examples are proposed product and its safety aspects, emergency planning and forecasting of emergencies, refresher courses etc.

3 **Long-term (strategic) plans** - For a period of 5, 10, 15 or more years. It considers future changes in environment and provides overall targets toward which all activities of the organisation are to be directed. It results in long term commitment of resources. It takes a macro view of the organisation and provides direction for the growth of the enterprise. It involves uncertainty because of the long period. Examples are environmental impact assessment, future opportunities, scientific development and its forecasting, future need of people and market trends, future expansion, competition etc.

Variety (types) of Plans : They are classified as under -

1. Based on objectives - Production plan, sales plan, financial plan, investment plan, expansion plan, research and development plan, training plan, existing business plan, reform oriented plan etc.
2. Based on time - Short, medium and long term plans as explained earlier.

3. Single use plan - Programmer projects, budgets etc.
4. Repeated use (standing) plans - they consider objectives, policies, procedures, rules and strategies.

Strategic Planning:

The word 'strategy' is used in military indicating its art (technique) of fighting the enemy. In business or industry it means a special type of plan to meet challenges, competitions, emergencies and other environmental forces. On-site and off-site emergency (contingent) plans are the best examples of such strategic planning. Their details are given in Part 7 of Chapter - 19. Strategic Plan is a master plan for the whole company and is framed by the chief executive, top level management or experts on the subject.

Definitions:

1. **McFarland** - Strategy is the executive behaviour whose purpose is to achieve success for the company or personal goals in a competitive environment based on the actual or probable action of others.

2. **Stoner and Wankel** - Strategic planning is the formalised, long range planning process used to define and achieve organisational goals.

3. **Koontz and Weihrich** - Strategic planning means to analyse the current and expected future situation, determine the direction of the firm and develop means for achieving the mission.

4. **D. L. Cleland and W.R. King** -Strategy is the complex plan for bringing the organisation from a given posture to a desired position in a future period of time.

Thus strategic planning links the resources of the organisation with the risks and challenges posed by external forces and lays down a long-term direction for the enterprise. In this sense strategic safety plans means on-site and off-site emergency plans to fight internal and external grave emergencies and long-term s public awareness and involvement programmes to deal with public or massive emergency due to industrial disaster.

Nature (characteristics) of Strategic Planning :

1. It is a long-term planning to fight future external forces.
2. It is action oriented, flexible, dynamic and forward looking.
3. It deals with basic questions.
4. It is a function of the top management.
5. It becomes a base for the detailed plans.
6. It focuses on energies and resources.
7. It analyses the environment.
8. It evolves assumption of certain calculated risks.
9. It is a contingent plan to meet demands of a particular situation.

Essentials (evaluation) of a good strategic plans:

Factors governing are.:
1. Internal consistency.
2. Consistency with environment.
3. Appropriate time horizon.
4. Realistic.
5. Acceptable degree of risk.
6. Feasibility and

7. Social or legal sanction.

Need of Strategic Planning : Need, advantages or importance of strategic planning are :

1. Helps in facing environmental or future challenges.
2. Provides direction.
3. Improved functioning.
4. Exploiting favourable opportunities.
5. Minimisation of chances of mistakes or losses.
6. Effective/efficient utilisation of resources like time, money, talent, equipment etc.
7. Facilities co-ordination and control
8. Competitive strength.

Process (steps) of Strategic Planning :

1. Decide mission and long range objectives.
2. Collect and analyse relevant information.
3. Assess the environmental and risk factors.
4. Conduct - resource audit (self-appraisal).
5. Think of strategic alternatives.
6. Select the best alternative (decision making).
7. Implement and control it.

Develop programmes and budgets for each function. Short term operational plan should b(prepared to utilise the resources. Proper sequence and timing efforts are decided to take every step at the right time. Performance should be evaluated, where result; are below expectations, strategy should be reviewed and modified as per need.

6.3.3 Organising for Safety :

Meaning:

The term 'organisation' is used in management in different ways as under

1. It refers an activity, process or function of management i.e. organising.
2. It is used in a dynamic way referring to e process by which the structure is created maintained and used.
3. It is used in a static way referring a static structure (skeleton) of responsibilities anc authorities i.e. a network & relationships among individuals and positions in an organisation.
4. It refers to an ongoing business unit i,e. a unit which is purposefully created to attain some objectives with resources.

Definitions:

1. **Joseph L. Massie -** Organisation is defined as the structure and process by which co-operative group of human beings allocates its tasks among its members, identifies relationship and integrates its activities towards common objectives.

2. **McFarland -**It is an identifiable group of people contributing their efforts towards the attainment of goals.

3. **Haimann-** Organising is the process of defining and grouping the activities of the enterprise and establishing the authority relationships among them. In performing the organising function, the

manager defines, departmentalises and assigns activities so that they can be most effectively executed.

4. **Chester Barnard** -It is a system of co-operative activities of two or more persons.

5. **L .Urwick** - Organisation is the process of dividing up of the activities which are necessary to any purpose and arranging them in groups which are assigned to individuals .

6. **John Pfiffner** - It is essentially a matter of relationship of man to man, job to job and department to department.

7. **Mooney & Reily** -It is the form of every human association for the attainment of a common purpose.

8. **Kimball & Kimball** - Organisation is subsidiary to management. It embraces the duties of designating the departments and personnel that arc to carry on the work, defining their functions and specifying the relations that are to exist between departments and individuals.

9. **Louis Alien** - Organisation is a process of (i) identifying and grouping the work to be performed (ii) defining and delegating responsibility and authority and (iii) establishing relationships for the purpose of enabling people to work most effectively together in accomplishing objectives.

10. **G. R. Terry** - Organising is (i) the establishing of effective behavioural relationships among persons (ii) so that they may work together efficiently and (iii) gain personal satisfaction in doing selected tasks (iv) under given environmental conditions (v) for the purpose of achieving some goal or objectives.

11. **Johnson, Kast and Resnzweig** - Organisation is an assemblage of people, materials, machines and other resources geared to task accomplishments through a series of interaction and integrated into a social system.

The main points that follow from above definitions of organisation are :

1. A business unit is divided into different sections or departments.
2. Each section or department is assigned a definite function or duty.
3. The authority and responsibility of each section or department or a group of people are clearly defined.
4. The interrelationship among various departments and among the groups of people working in them is clearly specified.

See Fig. 6.7 for a general organisation structure.

Fig 6.7 - Organisation Structure

Safety Organisation defined : Inferring from above general definitions. Safety organisation can be defined as the structure and process by which groups of people (employees) are divided into sections or departments, each section or department is assigned specific safety function or duty. Authority and responsibility of everybody is clearly defined and interrelationship between them is specified for the accomplishment of organisational safely goals.

A large unit may have safely department which may have groups of people for division of such safety function and responsibilities. But in a small unit (majority) if such division is not possible and only a few persons are available for safety work, they will be assigned specific duty and other departmental heads (production, purchase, personnel etc.) will be explained their role and responsibility towards safety goals. All supervisors shall be integrated with safety as part of their duty. 'Safety is everybody's duty' will be explained to all with their safety duty given in writing or by displaying at their workplaces.

Need (Significance) of Organisation : Organisation is the foundation or framework of the whole structure of management and contributes greatly to success and continuity of an enterprise in the following ways -

1. Facilitates administration and other functions of management process.
2. Facilitates growth and diversification.
3. Permits optimum use of technological improvements.
4. Encourages use of human beings.
5. Stimulates creativity.
6. Attains maximum efficiency with minimum costs.

Planning is the brain of a business unit while organisation is its physical structure. All managerial functions like planning, directing, co-ordinating, controlling, budgeting, staffing etc. are performed %· through the medium of organisation.

Its importance is remarkably explained by Andrew Carnegie (American industrialist) : "Take away our factories, take away our trade, our avenues of transportation, our money. Leave us nothing but our organisation, and in four years we shall have re-established ourselves".

Nature (Characteristics) of Organisation : Briefly they can be stated as under

1. It is a set up to realise the objectives (common purpose).
2. It is a co-operative activity.
3. It is a process (function) and structure both.
4. Division into Departments or groups. Division of labour.
5. Delegation of authority and responsibility. The chain of superior - subordinate relationship is known as 'chain of command'. (Authority structure).
6. Importance of human element (people).
7. Vertical and horizontal relationship between man to man, job to job .and department to department.
8. It is closely linked with planning. Other functions of management are not possible without organisation.
9. It is flexible and accommodates environmental changes.
10. It is stable and resists challenges.
11. Provides supervision, control and review.
12. Provides mechanism of co-ordination.
13. Provides channels of communication.
14. Provides policies, procedures, rules and regulations for systematic functioning.
15. Backbone of management and regenerates everything from beginning.

Principles of Organisation (Features of a good Organisation Structure) : They are summarised as under

1. Unity of objective - all are geared to common objectives.
2. Span of control - each superior has limited subordinates to report him.
3. Unity of command - each subordinate has only one superior to get command.
4. Scalar principle - clear chain of command from top to bottom.
5. Co-ordination - should exist among all individuals and groups.
6. Communication - should be open and clear.
7. Facilitates leadership.
8. Parity of authority and responsibility - exist by way of delegation.
9. Exception principle - only matters beyond control may be referred to higher levels.
10. Functional definition - Functions (duties), authority and responsibility of every position should be clearly defined so as to avoid duplication or overlapping.
11. Efficiency - optimum use of resources at minimum possible costs.
12. Flexibility - should accommodate changes.
13. Stability - should resist challenges.
14. Continuity - by training and development of executives and employees.
15. Balance - between centralisation and decentralisation.
16. Division of work - one member one function.

17. Unity of direction - clear-cut direction at all levels. Directions should be simple, easy to understand and unambiguous.

18. Simplicity and clarity - they add to efficacy of organisation.

Organisation for Safety: See Part 6.3.1 of this Chapter 'General and Scientific Functions'.

Safety Department : See Part 8 of this Chapter.

Safety Committee : See Part 11.3.1 of this Chapter.

Types of Organisation : There are seven types of organisation:

1. Line, military, scalar or vertical organisation.
2. Line & staff organisation.
3. Functional organisation.
4. Product organisation.
5. Project organisation.
6. Matrix organisation, and
7. Committees.

In 'Line organisation' line of authority is vertical flowing from top to the bottom and no staff specialists. In 'Functional organisation' the whole task is divided' into specialised functions (departments) and horizontal relationships also exist.

Line & Staff Organisation : 'Line & staff organisation' is a combination of line and functional structures, line of authority flows in a vertical line, but staff specialists are attached to line positions to advise them on important matters and these specialists do not have power of command over subordinates in other departments, but they possess it over subordinates in their own department e.g. Chief Safety Officer has command over safely officers in his department but he has no command over accounts officer in other department. He has only advisory relationship with other departments like production, personnel, HRD etc. A common model of line & staff organisation is shown in Fig. 6.8.

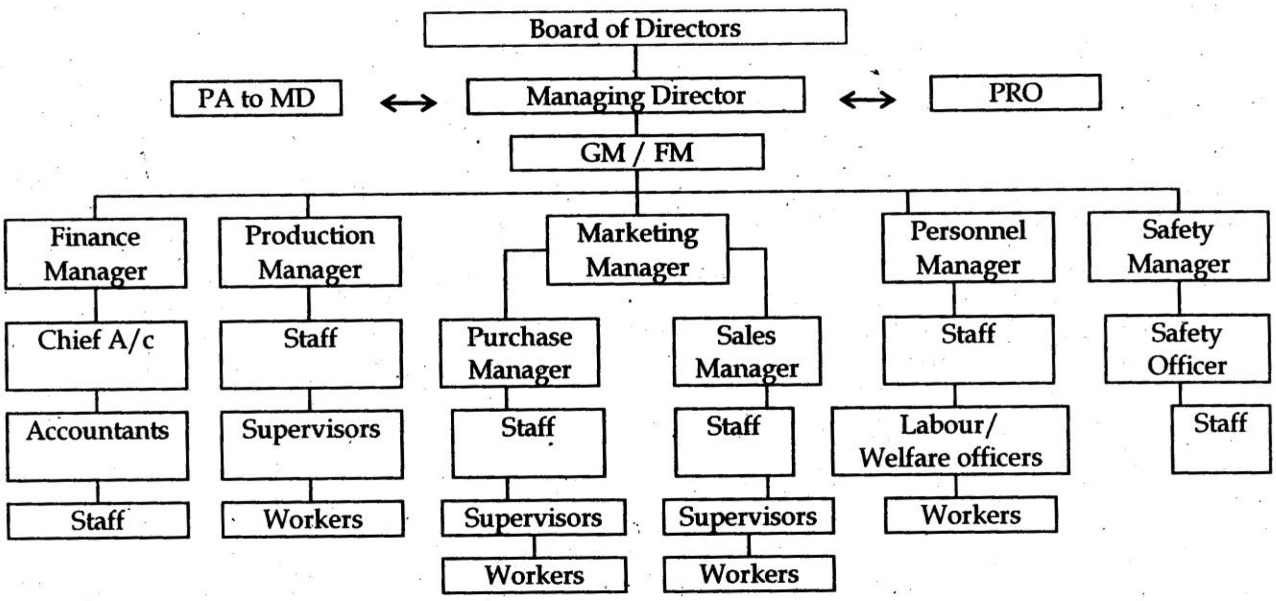

Fig. 6.8 : Line and Staff Organisation

No.	Advantages	Disadvantages

1.	Relief to line managers	Line-staff conflicts
2.	Expert advice (specialization)	Confusion in relationships
3.	Better decisions	Staff becomes ineffective or irresponsible
4.	Training of personnel	Expensive for small units
5.	Flexibility – opportunity for advancement	

Line & Staff Function of Safety :

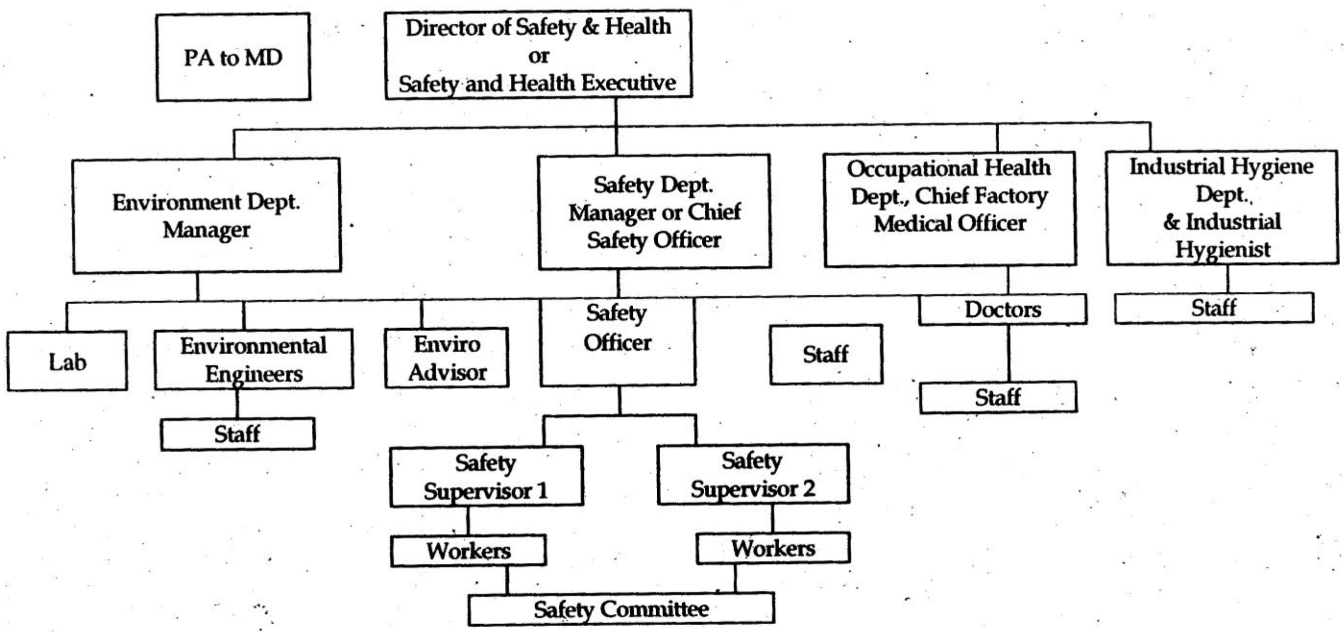

Fig. 6.9 : Line & Staff Organisation for Safety

One model of line & staff organisation for safety is shown in' Fig 6.9. For another model see Fig 6.6 of this Chapter.

Director or Safety & Health Executive is at the D of the line of authority. He has PA for assistance. Under him there are Managers for Safety, Occupational Health, Industrial Hygiene and Environment departments. They are reportable to Director but not to each other. They may consult or advise each other but cannot compel work. Safety Manager has Safety Officer(s) with staff. They have Safety Supervisors under them who supervise their respective areas and workers allotted to them. Similarly Health department has doctors under them with OHC. Environment dept. has enviro engineers, lab and staff.

Functions of safety department are mentioned in details in Part - 8 and Part - 6.3.1 and 6.3.2 of this Chapter.

6.3.4 Directing for Safety :

Meaning:

Once the objectives are decided and planning is made how to achieve them, organisation structure is designed by staff, appointing qualified and experienced persons and the organisation can be said ready for action. But this action cannot begin until orders and instructions are issued i.e. the employees are 'directed' to carry the orders. This process of inspiring and guiding people what to do and how to do the best of their ability is known as 'directing'.

Thus after planning, organising and staffing,, directing is the fourth managerial function. It is that part of the management process which guides, inspires, instructs and harnesses people to work effectively and r efficiently to achieve the goals.

Definitions:

1. **Urwick and Brech** - Directing is the guidance, the inspiration, the leadership of those men and women that constitute the real core of the responsibility of management.

2. **J. L. Massie -** Directing concerns the total manner in which a manager influences the actions of subordinates. It is the final action of a manager in getting others to act after all preparations have been completed.

Process : The process of directing consists of , the following steps :

1. Issue orders and instructions. They should be clear, complete and within capabilities of the followers.
2. Provide and continue guidance and supervision to ensure that the assigned tasks are carried out effectively and efficiently.
3. Maintain discipline and reward for good work.
4. Inspire and motivate to work hard to achieve the goals.

Thus motivation, supervision, leadership and communication are the main elements of directing.

Nature of Direction : The main characteristics of directing are:

1. Pervasive function - every manager has to guide and inspire his subordinates.
2. Continuing or on-going function.
3. Linking junction between preparatory functions (planning, organising and staffing) and controlling.
4. Creative function - It converts plans into performance. It is the management in actions. It brings life for organisation.
5. Human factor - involves human behaviour for which motivation is useful
6. Chain of command - It flows from top to bottom. Each superior directs his subordinates.

Role (benefits) of Direction :

It (1) initiates action (2) ensures coordination (3) improves efficiency and effectiveness (4) facilitates change and (5) assists stability and growth.

Principles of Direction : They are :

1. *Harmony of objectives* - Management should take care of personal goals of employees with the organisational goals.
2. *Unity of command.* - One subordinate should get orders/instructions from one superior only.
3. *Direct supervision* - There should be personal or direct supervision.
4. *Good communication* - Helps to improve understanding and speed of work.
5. *Maximum contribution* - Managers should try to get maximum possible contribution from each subordinate.
6. *Appropriate techniques* - The techniques should be suitable to superior, subordinates and situation to get efficiency.
7. *Strategic use of informal organisation* - Some informal groups should be contacted to decide direction.

8. *Comprehension* - Orders should be clear, complete and understandable.
9. *Good Leadership* - Managers should guide and counsel subordinates to win their confidence and trust.
10. *Follow-up* - Managers should follow-up their orders and modify if necessary.

Techniques of Direction : Generally four techniques are available for directing. They are delegation of authority, supervision, orders and instructions.

By delegation of authority a superior entrusts his subordinates with certain rights or powers. He assigns a part of his work and authorises him to do work.

Supervision means expert overseeing of subordinates at work to ensure compliance of plans and procedures. At operating level it is most useful and effective.

The terms order, instruction, directive and command are used interchangeably in management literature. They mean to initiate , modify or stop an activity. It is a primary tool by which activities are started, altered, guided and terminated.

Above definitions, principles and techniques of direction are equally applicable to the area of safety and safety managers should know an4 follow them while guiding, inspiring, motivating and instructing workers to detect and remove unsafe conditions and actions and to maintain safe environment in their day to day activities.

6.3.5 Leadership :

Meaning:

It is an indivisible part of the process of directing as explained in earlier part. It is a tool or means which makes direction effective. Dr. Terry says that managers have to manage business which means that they have to provide leadership. They have to instil in them desire to achieve the goals, a desire to improve their performance and a sense of co-operation. If the managers fail to provide such 'leadership the employees will search the leadership outside which may lead to conflict or distraction.

Definitions:

1. Koontz and. O'Donnell - Leadership is influencing people to follow in the achievement of common goal.
2. Terry - It is the ability of influencing people to strive willingly for natural objectives.
3. R. T. Livingston - It is the ability to awaken in others the desire to follow a common objective.

Role and Functions of a Leader :

1. He should be clear about common objectives (goals) and should communicate them clearly.
2. He has to influence, guide, instruct, inspire and supervise his subordinates to work efficiently and effectively.
3. He has to generate (awaken) desire in followers to achieve the common goal.
4. He works along with his followers, shows them how to work and gets their co-operation in return.
5. He should convince the followers that in protection of organisational (group) goals, lies the protection of their personal goals.
6. He has to provide continuous guidance till the achievement of goals.
7. Depending on situation he should alter, modify or stop order and should not be rigid in his decision.

8. He has to set an example by his own behaviour. Urwick has rightly said that It is not what a leader says, still less what he writes, that influences subordinates. It is what he is. And they judge what he is by what he does and how he behaves'.

Attributes of a Leader : Certain qualities are necessary for leadership but they must be applied at the correct place and time. Dr. Terry mentioned following qualities of a leader -

1. *Energy* - Physical and mental fitness to work by self and to guide for a longer time.
2. *Teaching ability* - He should be a good teacher.
3. *Emotional stability*- should be free from bias and anger and not emotional.
4. *Empathy* - It means the ability to understand other's viewpoint. He should have respect for others and their beliefs.
5. *Objectivity* -He should be objective to others and should find out reasons for requests or refusal by his subordinates.
6. *Enthusiasm* - is required in leader. He should be self motivated and capable of motivating others.
7. *Knowledge of HR* - Leader has to deal with human beings and therefore he should posses knowledge of human resources.
8. *Communicative skill* - He should be effective in his speech, talk and forceful impression.
9. *Social skill* - He should mix with his followers freely and socially. He should appreciate others' opinion and work with close co-operation.
10. *Technical competence* - Doubtlessly he must be technically more competent so that he can successfully teach technical aspects.

Leadership Styles (Techniques) : They are of three types -

1. Autocratic or Dictatorial leadership.
2. Democratic or Consultative or Participative leadership.
3. Free .Rein or Laissez Faire leadership.

In autocratic leadership subordinates have less freedom which increases in democratic leadership. Superior enjoys more authority in autocratic leadership arid less authority in democratic leadership. See Fig 6.10.

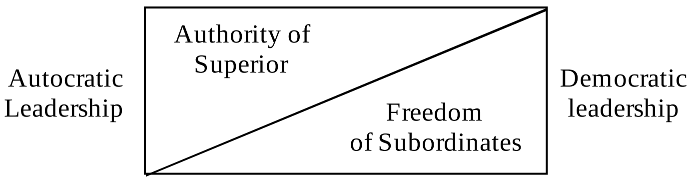

Fig 6.10 Relationship of two types of leadership

Autocratic leadership is useful when subordinates are illiterate, unskilled, untrained and secrecy in decision making is required. It can be applied when there is a clear chain of command or clear-cut division of authority. Its features are retention of power, relying on orders only and close supervision.

In **democratic or consultative leadership** method, the manager consults his subordinates and invites their suggestions before making decision. Formal or informal meetings are also held. Here subordinates work heartily because their views and opinions are respected. Close personal contacts and clear understanding of problems are ensured. It develops trust, co-operation and leadership among employees. This stage is useful when subordinates are literate, have sense of responsibility and organised. It requires much time in decision making.

In **free - rein leadership** technique, the manager delegate authority to his subordinates and they are encouraged to develop and contribute independent thought and action. This method is preferred mostly by highly educated and independent (free minded) persons. Here details are prepared by the subordinates. There is a free communication between superior and his subordinates. They don't feel difficulty in consulting each other. It is more creative and develops latent abilities of subordinates.

Selection of leadership style depends on (1) force in Manager (2) force in Subordinates and (3) force in Situation.

In Safety Management, autocratic leadership style is not suitable as safety is not to be imposed like military discipline, and involvement of employees (educated or uneducated) at all levels is required. The concept of employees participation, safety committee, safety education and training and "Safety is everybody's duty" can be well implemented by democratic or consultative leadership style. In designing safely guard or its improvement by ergonomic factors, developing safe work method, meeting safety targets by group co-operation, celebrating safety programme, creating and maintaining safety awareness and emergency preparedness, suggestions and involvement in decision-making of employees are most useful. Therefore, democratic leadership style at workers and middle level and free-rein leadership style at higher (executive) level are desirable for safety management.

6.3.6 Communication :

This is another element of the management 'directing' and also useful for» effective motivation, supervision and getting the work done.

Motivation cannot succeed without communication. It is a process involving the transmission and-reception of message, eliciting meaning in the mind of the receiver and resulting in appropriate action which is desired.

Though one way communication such as speech, posters, instruction, radio, TV has their uses, two way communications is the only effective way to transfer an idea from one mind to another. Two way communications allows for clarification and amplification.

Safety communication should be more clear, loud and effective. By good efforts create responses, desires, insight and action as soon as possible. Audio visual display, transparency arid modern teaching aid should be used for effective communication.

Definitions and Meaning:

1. **Haimann** - Communication means the process of passing information and understanding from one person to another. It is the process of imparting ideas and making oneself understand by others. It is fundamental and vital to all managerial functions.

2. **Newman and Summer** -It is an exchange of facts, ideas, opinions or emotions by two or more persons.

3. **Koontz and O'Donnell** -It is an intercourse by words, letters, symbols or messages, and is a way that one organisation member shares meaning and understanding with another.

Chester Bernard has stated "'The first executive function is to develop and maintain a system of communication".

It is communication when we speak, tell, write, read, watch, listen, hear or act or convey or transmit our message by expression or any other way of understanding feeling, attitudes, wishes, ideas, opinions, emotions, thoughts etc. Poor communication creates problem and good communication solves it.

Purpose (Role or significance) of Communication :

1. It is utmost necessary for planning, decision making, organising, directing and controlling.
2. Plans cannot be implemented without effective communication.
3. Its basic purpose is to create mutual understanding and to secure desired response.
4. Motivation and morale can be boost up.
5. Human relations can be improved.
6. Training and development is not possible without communication.
7. Co-ordination can be bridged by communication.
8. Public relations can be maintained and strengthened.
9. It increases productivity and performance.
10. It assists other functions.
11. It gives job satisfaction.
12. It is a basis of leadership.
13. It gives success to enterprise.

Process of Communication : According to Shannon and Weaver, it consists of following components or elements:

1. *Sender* - One who sends a message.
2. *Message* - What is conveyed by the sender.
3. *Encoding* - Words, symbols, gestures etc. by which the message is transmitted.
4. *Channel* -Medium or route through which, the message is passed" i.e. face to face, talk, phone, pager, radio, TV, letter etc.
5. *Receiver*- Who receives the message. He may be a listener, reader or observer.
6. *Decoding* - The process of understanding or interpreting by the receiver.
7. *Feedback* - Means reply, response or acknowledgement of the receiver that he has understood the message. It may be by words, actions or expressions. When the sender receives such feedback, the process of communication becomes complete. See Fig. 6.11.

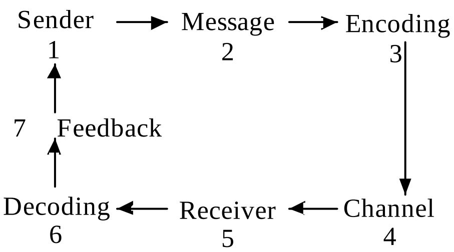

Fig. 6.11 The Process of Communication

Nature of Communication :
1. It is a continuous process. Its stoppage means stoppage of human activity.
2. It is a two way process between sender and receiver.
3. It creates mutual understanding and human relation.
4. It is a pervasive function i.e. required in all managerial functions.

Types of Channels and Media of Communication:

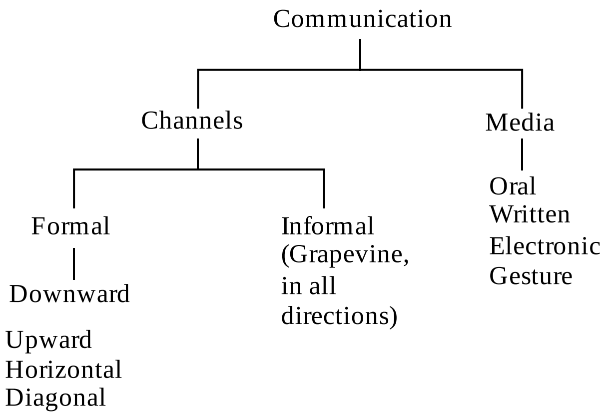

Fig 6.12 Channels & Media of Communication

A communication channel is a route through which messages flow from the sender to the receiver. It is either formal or informal. Formal (planned or systematic) communication may flow in downward, upward, horizontal or diagonal direction and creates communication networks. Informal i.e. unofficial or inter-personal (unplanned and need base) communication flows in all directions and therefore it is called structure less or grapevine. Type of communication media are oral, written or gesture i.e. implied or posture. See Fig. 6.12. Their differences are shown below:

No.	**Formal Communication**	**Information Communication**
1	Official Channel.	Unofficial Channel.
2	Intentional, deliberate, planned or systematic.	Interpersonal, unplanned or spontaneous.
3	Impersonal.	Personal and Social.
4	Slow and structured.	Fast and unstructured.
5	Stable and rigid.	Flexible and unstable.
6	Oriented towards goals and tasks.	Directed towards goals and need satisfaction.
7	Part of organisation structure.	Cuts across formal relationship.
No.	**Downward Communication**	**Upward Communication**
1	From higher to lower level.	From lower to higher level.
2	Flows downward and fast.	Flows upward and slow.
3	Directive in nature.	Non-directive.
4	Purpose is to get plans implemented.	Purpose is to provide feed back on performance or to ask something.
5	Examples: Orders, instructions, lectures, manuals, handbooks etc.	Examples: Reports, queries, Suggestions, appeals, protests, grievances, surveys etc.
No.	**Oral Communication**	**Written Communication**
1.	Generally informal.	Generally formal
2.	Involves talking and listening.	Involves writing and reading.
3.	Feedback is quick and instantaneous.	Feedback is delayed due to time of transmission.
4.	Economical.	Expensive and stable.
5.	Flexible and faster.	Rigid, slow and elaborate.
6.	Suitable for short messages.	Suitable for lengthy and organised messages.
7.	No permanent record. Hear and forget. Recording is possible	Authentic and credible record is possible.
8.	Examples : Face to face talk, group meetings, phone etc.	Examples : letters, memos, CDs, handbooks, manuals reports, Email, etc.

Difference of Types with Media:-

Oral	Written
Downward Communications :-	
Personal instructions, lectures, meetings, conferences, interviews, employee counselling, bells, whistles, telephone, movies, slides, public address system (PAS), social and cultural gatherings, union activities.	Orders and instructions, letters, Email, circulars, memos, posters, bulletin, house organs, handbooks, CDs, manuals, annual reports, policy statements, union publications, informational racks.
Upward Communications :-	
Face to face talk, oral report, exit interviews, phone, meetings and conferences, social and cultural affairs.	Personal letters, Email, written reports, CDs, suggestion scheme, grievance procedure, surveys, unions publications.
Horizontal Communications :-	
Lectures, talks, meetings and conferences, phone and intercom, movies and slides, social affairs, union activities.	Letters and memos, reports, carbons, memo, graphs, posters, bulletin, handbooks, manuals, house organs, union publications, Email.
Diagonal Communications :-	
Inter-departmental oral inquiry, talks and meetings, phone and intercom to other department, social gatherings of mixed groups.	Inter-departmental letters, memos, reports, suggestions, objections. Email etc

Tools of Communication : They are the means through which information is communicated. They can be classified as under:

Oral (Verbal) : Personal contact, talk, phone, meetings, audio, video etc.

Written : Letters, circulars, memos, reports, notices, handbooks, manuals, booklets, magazines, bulletins. Email etc.

Visual: Newsreel, film, video, play, posters, pictures, boards etc.

Informal : Casual or incidental talk, meetings etc.

Barriers to Communication:

Despite of growth in communication system and modern electronic media, it may fail due to following barriers or obstacles.

1. Incomplete, ambiguous or badly expressed message.
2. Absence of clarity of thought.
3. Absence of brevity and exactness, unwanted length, words, repetitions, over-elaboration etc.
4. Timeliness i.e. the message does not reach in time.
5. Lack of attention by the receivers.
6. Organisational barrier - Scalar chain of command, filtering of message, discouragement to informal communication, excessive control etc.

7. Status barrier - Subordinate has fear to report everything to superior and may hide unpleasant facts.

8. Perceptual barrier - Receiver may pay attention only on that part where he has interest or liking and may underrate or filter the message.

9. Information overload - Due to overload work, managers may ignore some message, may forget to inform some people or may send incomplete message.

10. Premature evaluation - The receiver evaluates the message before getting complete information i.e. he derives premature conclusion.

11. Channel distortion - Physical, Mechanical or electronic disturbance or mistransmission due to channel distortion.

12. Improper order of information.

13. Improper selection of medium.

14. Emotional or sentimental messages.

15. Change of meaning during transmission.

16. Unwanted assumptions either by sender or

Essentials of Effective Communication :

Rules, principles or guidelines of effective communication or the measures to overcome its barriers are as under:

1. Message should be clear, complete, unambiguous and expressed properly.
2. Information should be in proper order/sequence.
3. Medium should be proper and effective.
4. Channel should be sound and undistorted.
5. Clarity - There should be clarity of thought.
6. Brevity - Message should be brief, precise and perfect. Meaningless words, repetitions, and excessive details should be avoided.
7. Timeliness - Message should reach in time.
8. Compassion - Sender should be aware of level of understanding and background of the receiver.
9. Integrity - Message must be consistent with objectives, policies and programmes. Action and behaviour of the sender should support his message.
10. Feedback - There should be follow up action (if necessary) to get feedback.
11. Careful listening by the receiver is necessary.
12. Strategic use of grapevine - The sender should try to fill up gaps in formal communication by strategic use of informal channel.
13. Create a climate of faith, trust and good human relations to make the communication effective and respectful.
14. Communication should be purposeful, at propel speed, sound and with synchronising.
15. Line of communication (reporting) should be clear.
16. Evaluation of communication system is useful for improvement.

Two-way communication :

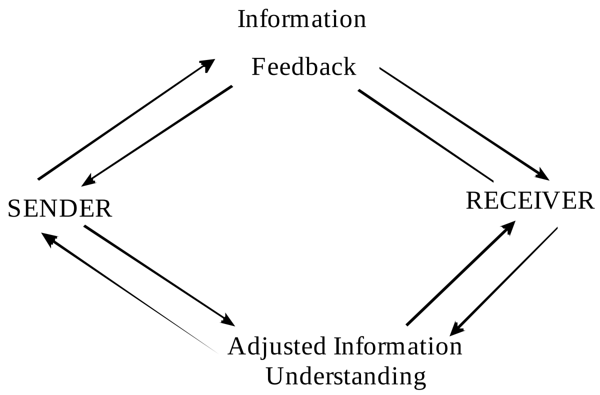

Fig. 6.13 Process of two-way communication

First a sender passes information to a receiver. He then gives feedback to the sender. If it is not as per expectation (correct),, the sender supplies adjusted information to the receiver. Then clear understanding takes place between them and in both the ways. Thus two-way communication (with correct feedback) is the effective communication. See Fig. 6.13

Ask the audience whether they have understood what you have explained. Get their feedback point or topic wise and then proceed further. One way transmission may go overhead. Therefore involve the listeners, ask questions, opinions and make the atmosphere live. First assess the needs, concerns, problems, age-group, levels of knowledge and experience of the participants and select the media and method accordingly. Effective listening steps are sensing, interpreting, evaluating and responding (feed back).

Group discussion, practical, assignment etc. are good programmes of two-way communication.

In two-way communication feedback is required which is not possible without good listening. Factors of good listening are :

1. Stop talking and thinking other subject.
2. Emphasize.
3. Maintain eye-contact.
4. Share responsibility for communication and
5. Clarify and interrogate if not understood. Two way communication is a key of success.

Communication and Group Dynamics :

Keith Davis defines "Group Dynamics" as the social process by which people interact face to face in small groups.

Group dynamics is the study of forces operating within a group. It is the study of field that deals with (1) Interactions and forces between group members in a social situation (2) The nature and development of small groups (3) Interactions among members and inter group behaviour (4) How a group should be organised and operated and (5) Nature, Structure and processes of a group, and their influence on the behaviour and performance of group members.

The assumptions underlying the study of group dynamics are as under:

1. Groups are inevitable and ubiquitous.
2. Groups can produce both good and bad consequences.
3. Desirable consequences from groups can be obtained through correct understanding of groups and their functioning.

4. Groups mobilise powerful sources that produce effects of utmost importance to individuals.

Kurt Lewin is considered to be the founder of group dynamics principle in management.

Group formation is a natural process everywhere, at home and at all work places. In industry the groups of workers does exist. By effective communication they should be motivated for safety. Instead of breaking their internal strength and informal relationship, it should be diverted to achieve organisational goals. Group training programme, group tour, group committee, group participation, group incentive and group targets can be organised by appropriate channels and tools of communication. Utmost care is required while addressing a group. Their dynamic strength should be well assessed and moulded by communication as desired.

Barry M. Staw suggests following steps to utilize groups to enhance satisfaction and performance :

1. Organising work around intact groups.
2. Having groups charged with selection, training and rewarding of members.
3. Using groups to enforce strong norms for on-thejob and off-the-job group behaviour.
4. Distributing resources on a group rather than on individual basis, and
5. Allowing and perhaps even promoting inter group rivalry (competition) so as to build within group solidarity.

The groups perform four functions of (1) Socialising the new employees (2) Getting the work done (3) Decision making and (4) Control measures.

Group dynamics states following characteristics of a group :

1. **Structure** - Each member occupies a position in the group depending on his status, power, experience, aggressiveness etc. Leadership is a special status.
2. **Roles** - Depending on position, the members perform three types of roles : expected role, perceived role and enacted role.
3. **Norms** - mean prescriptions for acceptable behaviour determined by the group.
4. **Informal managerial roles** - Managers can perform three types of roles (1) Interpersonal ' roles as a figurehead, leader and liaison officer (2) Informational roles as disseminator, monitor and spokesperson (3) Decisional roles as entrepreneur, disturbance handler, resource allocator and negotiator (Henry Mintzberg).
5. **Informal communication system** - or grapevine communications in all directions should be utilised to attain objectives.

Supervisors' good behaviour with their workers, informal relations and taking interest in their personal matters and paying constant attention for their individual growth, give desired results. Such behaviour is much more useful to make the workers safety Oriented. Sympathetic and fatherly behaviour is the best form of communication. Group dynamics should not disintegrate the organisation, rather it should strengthen integration. Art of communication should be developed for this purpose by giving special training to the superiors.

6.3.7 Controlling for Safety :

To complete the management cycle it is important to know about the function of controlling after knowing about planning, organising, staffing and directing.

Definitions:

1. **Koontz and ODonnell :** Managerial control implies the measurement of accomplishment against the standard and the correction of deviations to assure attainment of objectives according to plans.

2. **Robert N. Anthony :** Management control is the process by which managers assure that resources are obtained and used effectively and efficiently in the accomplishment of an organisation's objectives.

3. **Dr. George Terry :** Control is determining what is being accomplished, that is evaluating the performance and if necessary, applying corrective measures so that the performance takes place according to plans.

4. **Mary Gushing Niles :** Where planning sets the course, control observes deviations from the course and initiates action to return to the chosen or to an appropriately changed one.

5. **Peter F. Drucker :** Control maintains the equilibrium between ends and means, output and effort.

6. **Haynes and Massie :** Fundamentally Controlling is any process that guides activity towards some predetermined goal. The essence of the concept is in determining whether the activity is achieving the desired results.

7. **Henry Fayol :** In an undertaking, control consists in verifying whether everything occurs in conformity with the plan adopted, the instructions issued and principles established. It has for object to point out weaknesses and errors in order to rectify them and prevent recurrence. It operates on everything; people and actions.

8. **Hicks and Gullet :** Controlling is the process by which management sees if what did happen was what was supposed to happen. If not, necessary adjustments are made.

Thus controlling is aimed at (1) monitoring the outcome of activities (2) reviewing feedback about this outcome and (3) if necessary, take corrective action to achieve the outcome according to the plan.

Control function is closely connected to planning. It can be said an effective counterpart to planning.

Using these definitions, controlling for safety can be defined as "a process that verifies and guides activities towards predetermined (planned) safety goals and takes necessary action, if required, to achieve the goals."

Characteristics: Main characteristics (nature) of control are that it is (1) a system (2-) universal (3) a continuous process (4) forward looking (5) an influence process and (6) involving measurement.

Need (Purpose) : Its main purpose are (1) to measure progress (2) to uncover deviations or change, delegation, mistakes, complexity etc., and (3) to indicate corrective action.

Importance (benefits) : It offers (1) Guide to operations (2) Policy verification (3) Managerial accountability (4) Employee morale (5) Psychological pressure and (6) Co-ordination in action.

Types (Kinds) : Controls are of three kinds (1) Feedback control (2) Concurrent control and (3) Feed forward control.

Areas of Control: They are over (1) personnel (2) performance of production (with safety) (3) Finance and (4) Morale.

Steps (Elements) of Control Process : They are (1) Establishment of standards - qualitative and quantitative (2) Measurement of performance (3) Comparing performance with standards (4) Analysis of Deviations and (5) Taking corrective action.

Requirements of Effective Control System : The essentials are that the control systenn should be (1) Simple and easily understandable (2) Flexible and not rigid (3) Objective and need base (4) Forward looking (5) Prompt (6) Strategic point control (7) Motivating (8) Suggestive (9)-Economical and (10) Less time consuming.

Control Techniques: They include (1) Breakeven-analysis (2) PERT and CPM (3) Budgetary control (4) Zero based budgeting (5) Management Information System (MIS) and (6) Controlling or Monitoring by Safety Standards.

Controlling by Safety Standards:

This is an indirect way of controlling and improving safety standard of the company. Control by statutory provisions (See next Part 6.3.8) or standards are the first and legal requirement. In addition to this or in absence of this, national and international standards of safety should be followed. IS:14489 on Occupational Health and Safety-audit, OHSAS 18001 on Occupational Health and Safety Assessment Series, and ILO and EPA standards are available.

See Part 1.17 of Chapter-19.

If such standards are followed, they can help us in improving our safety standard (status) and recognition in the world market. Management control techniques should consider this aspect at the appropriate stage of the company.

For details of these standards, their document should be referred. Consultants are also available for guidance and preparation to get such standards.

Management by Exception (MBE):

It is a system or principle of managerial control based on the belief that effort of controlling everything results in controlling nothing and therefore there is no need to report performance within the permissible limits (i.e. acceptable deviations from the standards), but only exceptional (significant or major) deviation from standards should be reported to the management.

Benefits of this system are:

1. It saves time of Manager as they have to focus on exceptional matters. Routine problems are left to subordinates.
2. Managers can well concentrate on major problems .resulting in better utilisation of their talents and energy.
3. It facilitates delegation of authority for less important matters. This increases span o control and leads to motivation and development of subordinates.
4. It separates more and less important matters and tends managers to use knowledge of trends, history and available business data.
5. It keeps management alert to opportunities and threats by identifying critical problems.

6. It provides better yardsticks for judging results. It is helpful in objective performance appraisal

Management by Objectives (MBO) :

This concept was first given by Alfred Slown in 1950 but Peter Drucker popularised it in 1954 in his book 'The Practice of Management'.

This approach is also known as management by results, goal management, performance management and accountability management.

It is a system of management where (i) goals for the business as a whole are set and (ii) managers and staff members at every organisational level are actively involved in goal setting. The idea is that when employees are involved in goal setting for them, they will put their heart to achieve them.

Definitions:

1. **Peter Drucker -** Business performance require that each job be directed towards the objective of the whole business.

2. **George Odiorne** - It is a process whereby the superior and subordinate managers of an organisation jointly identify its common goals, define each individual's major areas of responsibility in terms of result expected of him and use these measures as guides for operating the unit and assessing the contribution of each of its members.

3. **W. J. Reddin** -It is the establishment of objective areas and effectiveness standards ' for management positions and the periodic conversions of these into measurable time bound objectives linked vertically and horizontally with future planning.

4. **S. K. Chakravarty** -It is a result oriented, non-specialist, operational managerial process for the effective utilisation of the material, physical and human resources of the organisation, by integrating the individual with the organisation and the organisation with the environment.

Nature (characteristics) of MBO :

1. It is a system approach integrating all employees for goal setting and achievement.
2. It is a behaviourist approach where human element is recognised at each level.
3. It is democratic approach because it is participative.
4. It measures results with the standards prescribed and suggests corrective measures.
5. It focuses on goals of the individuals and the organisation.
6. It has autonomous control because employees are not controlled from outside but they themselves evaluate their performance in terms of predetermined goals and devise corrective measures if their performance is below the norms.
7. It boosts up employees' morale and motivation because they are called for participation.

Process (steps) of MBO : Steps in sequence are:

1. Set objectives of the organisation.
2. Set objectives of the departments.
3. Set objectives of the individuals.
4. Develop action plans.
5. Implement plans.
6. Take periodic reviews.
7. Appraise results.

8. Take corrective action for improvement.

Advantages of MBO : They are :

1. Better management.
2. Clarifies organisation.
3. Harmony of objectives.
4. Motivation.
5. Evaluation of results.
6. Development of managers.
7. Improvement in superior - subordinate relations.

Scope (limitations) of MBO:

1. Difficulty of introducing for reaching changes.
2. Difficulty in setting goals.
3. Too much emphasis on results.
4. Pressure on employees.
5. Too high expectations.
6. Neglect of some important goals.
7. Not useful for all.
8. Rigidity.

Requisites (preconditions) of MBO :

1. Setting real objectives.
2. Ends - means distinction.
3. Clarity of objectives.
4. Active support from all participants
5. Active support of top management.
6. Three elements that objectives should be - helpful in evaluating performance, measurable and convertible into targets.
7. Multiple objectives and sub-optimisation.
8. Displacement of objectives.
9. Quantitative cum qualitative objectives.
10. Receptivity.
11. Training for fulfilment of objectives.
12. The 'why' spirit (why cannot be obtained?)
13. Individual growth.
14. Study of environment and flexibility.
15. Provision of performance.

Role of MBO in Safety : The concept of MBO is much more useful in setting and achieving safety goals because it is a participative approach and safety being everybody's duty and everybody's target (goal) this approach is best fitting for safety management.

First safety goals for the whole organisation should be decided by the safety department. They may be:

1. Safety policy.
2. Some million man-hours work without accident.
3. Clean environment at all workplaces.
4. Productivity with safety.
5. Hazards detection and removal.

6. Maintenance of guards and safety devices.
7. Use of safety equipment.
8. Accident reporting, detailed investigation and record for cost and lesson.
9. Safety inspections and control techniques.
10. Safety committee, its objectives and functions.
11. Ergonomic improvements.
12. Occupational health & hygiene.
13. Compliance of statutory provisions.
14. Formation of other safety rules for specific works, SOPs and safety permit systems.
15. Induction, on-going and periodical safety programmes.

All departmental heads should be involved in above goal setting and they should be convinced for their need and importance. These goals may 'be distributed department wise if possible e.g. training for training department. Then each departmental head will hold meeting of his employees and involve them in setting goals for their department. Departmental supervisors will observe fulfilment of these goals and guide their employees. Each employee will be fully convinced for his individual role and importance for the organisation, need for safety for himself and his family, cause and consequence of accident and use of his knowledge, experience and expertise in finding and removing hazards.

Lastly the performance will be measured against standards or expectation, evaluated, reviewed and reset with the participation of employees involved.

Thus the process of participation by MBO can be practised for safety to achieve desired results with live support and active atmosphere.

All above principles of Management must be utilised from planning to controlling stages of all programmes pertaining to industrial safety, health and environment. Goals must be set for safe design, construction, operation, maintenance, waste disposal, training, fire, first aid, medical check-ups etc. and their achievement should be monitored.

6.3.8 Statutory Duties of the Management :

Many safety statutes (as mentioned in Chapters 27. & 28) provide general and specific liability, responsibility or legal duties or obligations of the management. Such duties under two Acts are stated below. For other duties. Chapter 27 and 28 should be referred:

Under the Factories Act & Rules :

1. Approval, licensing and registration of factories and notice of occupation as well as notice of appointment of a new manager. Construct and run the factory according to the plans approved and statutory provisions.

2. To provide good hygienic conditions in respect of cleanliness, disposal of wastes and effluents, ventilation and temperature, dust and fume, artificial humidifications, overcrowding, lighting, drinking water, latrines, urinals and spittoons.

3. By sections 7A and 7B, general duties of occupiers, manufacturers etc. are imposed to ensure the health, safety and welfare at work of all workers in the factory. Plant and systems without risks, safety in use, handling, storage and transport of materials; information, instruction, training and supervision for the health and safety of all workers, safe places, means of access and conditions, provision, maintenance and monitoring of safe working environment and written statement of safety policy are necessary. An article is expected to be designed and constructed as to be safe and without risks. Safety instructions shall be supplied and followed.

4. Strict and absolute responsibility for safety is described for fencing of machinery, work on or near machinery in motion, employment on dangerous machines, striking gear and devices for cutting off power, self-acting machines, casing of new machinery, work near cotton openers, hoists and lifts, lifting machines, revolving machinery, pressure plant, floors, stairs and means of access, pits, sumps, openings in floors etc., excessive weights, protection of eyes, precautions against dangerous fumes, use of portable electric light, explosive or inflammable dust, gas etc., precautions in case of fire, safety of buildings and machinery and provision of safety officers. Various rules are prescribed under these provisions for textile, cotton ginning, wood working, rubber mills, centrifugal machines, power presses, shears, slitters etc. and some 27 types of dangerous operations and hazardous processes. (Rule 102 GFR).

5. By insertion of new sections 41 B and 41 C specific responsibility of the occupier in relation to hazardous processes (defined by section 2 (cb) and listed under the First Schedule) is imposed. This requires disclosure of information regarding dangers and health hazards, measures to overcome them, policy statement, on-site emergency plan and disaster control plan, publicising to workers and public, medical records of the workers and appointment of qualified and experienced persons to supervise handling of hazardous substances.

6. Provision and maintenance of various welfare facilities for washing, storing and drying clothing, sitting, first aid, canteens, shelters, rest. rooms and lunch rooms, creches, and Welfare Officers.

7. Duties for observing working hours, employment of young persons and women, annual leave with wages to workers, notice of accidents, dangerous occurrences and disease maintenance of various statutory forms, records and registers and supplying identity cards, leave cards, safety policy etc. to workers are also prescribed.

The Chief Adviser, Factories, Ministry of Labour Govt. of India, New Delhi, explains responsibility of occupiers under the Factories Act, 1948 in the following words:

"The responsibility for safety matters is -placed squarely on the shoulder of the occupier. He must comply with the safety provisions of the Act without waiting for an Inspector to visit and give instructions for what ought to be done. Unless the employer undertakes this duty, there are no. means of ensuring that this important provision will be observed. If, he shows himself determined to secure the use and maintenance of guards, he can effect this object. It is a very important point for the occupier to note, the requirements of the Act are absolute and are in no way dependent upon previous notice or warning from the Inspector'".

See Part 5 of Chapter-27 also.

Under the Environment (Protection) Act 1986:

1. Persons carrying on industrial operations etc. shall not allow emission or discharge of environmental pollutants in excess of the standards.
2. Persons handling hazardous substances shall comply with safeguards prescribed.
3. The occupier shall furnish information to authorities, allow their entry, inspection and sample testing.

Similarly, under other Safety Acts and Rules, I numbers of statutory duties are prescribed for ' management.

6.3.9 Overview of Safety Activities :

As explained in part 6.3.1 above, six functions of a scientific management reveals that safety can best be executed by a good management only and this is possible by constant over viewing of safety activities by the management.

What should be overviewed? Good planning of safety activities and statutory duties described in part 6.3.8 above, best organisational structure and staffing for it and constant direction, control -and coordination for all safety activities are to be overviewed to implement and achieve the desired safety targets.

6.3.10 Division of Responsibilities :

No management can succeed without distribution of responsibility at different levels or lines and proceeding through all such levels.

The words "responsibility", "accountability" and "authority" are used side by side creating confusion. Their deference is as follows.

Responsibility is a duty or activity assigned to a given position (s). It comes with authority. It requires answering for activities and results for targets.

Accountability is an active measurement by management to ensure compliance with its intentions.

Authority is the right use of power. Responsibility and authority should match with each other. We cannot hold a person responsible for an act unless he is properly authorised for that.

Duties and authority can be delegated but not the responsibility. A supervisor is always responsible for the actions of his subordinates and cannot escape from his responsibility by delegation.

It is accepted by good management that (1) Safety is a line management responsibility (2) Management should formulate safety accountability. The line of responsibility starts from the top executives.

Safety Responsibilities of Directors and Senior Management:

1. Legally and otherwise, top management is responsible for safe mechanical, physical and all working conditions created by them and under their control.

2. Because of its ability and opportunity it is also responsible for preventing unsafe actions of its work people.

3. By proper selection, training, instruction and supervision the top management should carry out above functions.

4. The occupier or the director so notified are responsible for compliance or breach of all statutory duties and liabilities explained in part 6.3.8 above. Not only the legal, it is their financial and human responsibility also.

5. Line managers have to carry out the safety policy approved by the board. They should promote and encourage awareness and willing acceptance of importance of safety among their staff.

6. Senior Managers have a similar responsibility for safety as for productive output and should ensure that this responsibility is accepted and shared throughout all supervisory levels. They must provide personal leadership in carrying out the policy, in participating in safety committees, in

introducing programmes, considering all accident investigations and setting a personal example in observation of safety regulations in their day to day work. They should also keep the board informed of the progress in implementing the policy, of supplying data on safety for the guidance of the board and making recommendations necessary for improving safety standards. They should recognise efforts of the staff who seek to improve safety. They should also be ready to take, any disciplinary action for breach of safety duty of the company's safety regulation.

Roles of others are explained in Part 6 to 8.

6.3.11 Location of Safety Functions :

After dividing the responsibilities up to supervisor's level it is necessary to fix the location of safety functions. Area jurisdiction of plant, department, shop, section should be decided and distributed along with the responsibilities. Who will carry out what function, where, who will report to whom, where the tools, equipment, records, registers lie, who will inspect, who will carry out job safety analysis, hazard analysis, HAZOP study, training and teaching etc. must be decided for smooth direction and co-ordination. They all should have common awareness for insisting to provide guards, wear safety equipment and to follow safe practices.

6.4 Safety and Purchasing Policy :

This is a 'planning' function of a management.

Definitions of Policy:

- **Koontz and O'Donnell** - Policies are general statements of understandings which guide or channel thinking in decision making of subordinates.

- **Dalton McFarland** - Policies are planned expressions of the company's official attitudes towards the range of behaviour within which it will permit or desire its employees to act.

Policy may be express or implied, verbal or written. Mostly it is in a short document form in writing. Objectives indicate destination and policy provides its route. Policy is the basic guidelines of attitudes, intentions, commitments or determination of the top management telling employees and the public its broad objectives and means to achieve them.

Types of Policies: They are classified as basic, general or departmental policies, production policy, sales policy, purchasing policy, accounting policy, marketing policy, finance policy, personnel policy, safety/health or environment policy, imposed policy, appealed policy, originated policy, opportunism policy (in politics and military), restrictive or permissive policy '(nature), written or implied policy etc.

Safety Policy is statutorily required u/s 7A(3) and 41B(2) of the Factories Act, 1948 and its details arc prescribed u/r 12-C and 68-0 of the Gujarat Factories Rules, 1963. For details see Part 6.4 of this Chapter - 'Safety .and Purchasing Policy '.

Need and Importance of Polities : They

1. Operationalise objectives.
2. Save time and effort.
3. Facilitate delegation of authority.
4. Speed up decision making.
5. Facilitate administrative control.

Characteristics of a sound policy (Principles of Policy Making): It should be:

1. It is based on objectives and should indicate how to attain them.
2. Clear, definite, explicit, precise and easily understandable.
3. Indicative of criteria limits and yardsticks for action.
4. Stable as well as flexible.
5. Planned development.
6. With norms of ethical behaviour and legal standards.
7. Just, fair and equitable to internal as well as external groups.
8. Communicated to people for implementation and
9. Reviewed and periodically revised to keep upto-date.

Steps in Policy Formulation :

1. Define policy area.
2. Identify policy alternatives.
3. Evaluate policy alternatives.
4. Select the best alternative.
5. Make policy document (if more details are required then policy manual). Follow statutory guidelines.
6. Communicate for implementation.
7. See its application into operational plans and all activities.
8. Review and revise to keep it up-to-date.

Factors influencing Policy Making : They are :

1. Values and beliefs of the top management.
2. Objectives (goals).
3. Prevailing techniques.
4. Availability of finance.
5. Employee relations.
6. Effects on public.
7. Policies of competitors.
8. Government rules and control (legality).
9. General business environment.
10. Level of prices.
11. Public attitudes and behaviour

The first step or objective of any safety management is to formulate its clear safety policy. It should be in consultation with the Safety Department, in writing, and should be updated as requirement from time to time. Now this is statutorily required under sections 7A(3) and 41B (2) of the Factories Act.

Content of Safety Policy :

As per rule 12-C and 68-0, of the Gujarat Factories Rules, 1969, safety policy should contain –

1. Commitment of the top management to health, safety and environment and compliance of the statutory requirements.
2. Organisational set-up to carry out the policy.
3. Arrangements to make the policy effective.
4. Arrangements for involving workers.
5. Consideration of health and safety performance for career advancement.

6. Fixing responsibilities of contractors, subcontractors, transporters and other agencies entering the premises.
7. Declaring health and safety performance of the factory in its Annual Report.
8. Techniques and methods viz. safety audit, risk assessment, at an interval of 2 years, on the status of healthy safety and environment and taking remedial measures.
9. Arrangements for informing, educating and training workers and the public where required.

A copy of the policy shall be given to authorities, workers, contract workers, apprentices, transport workers, suppliers etc. It shall be displayed at conspicuous places. It shall be revised whenever any expansion, modification, use of new substance or ; articles affect the health and safety of persons at work.

Model Drafts:

Health and Safety Policy are given below. Though these drafts do not contain all nine items mentioned above, they are useful in drafting the safety policy. Guidelines of statutory rules should be included in the draft.

Draft-1 :

This (name) company recognises the importance of safety for all its employees and the general public. It will be our endeavour to decrease environmental loads, including noise, through effective application of available technical measures.

The company accepts this as one of the prime responsibilities and to achieve the above policy, the company adopts the following principles.

1. Matters concerning safety, health and environmental protection will have squal standing in our objectives to perform the business efficiently. These aspects will duly be considered during projects, planning and decision-making.

2. All the statutory regulations on health, safety and environmental protection will always be complied with. Besides the company will extend fullest co-operation to public agencies like Fire Brigade, the Collectorate, Police, in combating any off-site emergency. The company will maintain its On-Site Emergency Action Plan to a high degree of preparedness. In case of any emergency endangering lives of the people, safety and health protection will have the highest priority.

3. The plants, equipment, systems and working conditions will be provided and maintained to be safe and without risk to the health of all the employees, contractor's workers, public and the environment.

4. Safety, Health and Environmental protection is a collective responsibility. Every employee needs to contribute to the best of his ability. The contribution thus made shall be, one amongst other factors, the criteria for assessing the performance and potential growth.

5. Ensuring safety, health and environmental protection is the responsibility of the line functions. Safety and Environmental Protection Department will supplement the line functions as advisor.

6. The specific responsibilities will be clearly defined in the safety concept of the company.

7. Every supervisor , manager and specialist must update their knowledge on the applicable guidelines and apply them in their functions as an ongoing programme.

8. Necessary information, instructions and training programmes and safety publicity aids will be developed for inculcating safety consciousness amongst the employees and to enable them to perform their duties in a safe manner including contract employees and transporters.

9. Internal safety audit reports will be dealt as one of the most useful tools for the technical management priorities.

10. It will be our constant endeavour to make the technology environmentally-friendly and minimise the outflow of wastes.

Draft-2:

It is the policy of this (name) company to :

1. Provide and maintain, so far as is reasonably practicable, plant, equipment, systems and working conditions which are safe and without risk to the health of all employees, visitors, contractors and the public and which avoid damage to property and adverse impact on the environment;

2. Protect all employees from exposure to any substance or activity which may be hazardous to health by providing suitable control measures based on assessment of the risks and recommendations made through periodical safety audits;

3. Provide information, instruction, training and supervision for all employees to enable them to carry out their duties and responsibilities in a safe and effective way;

4. Develop and maintain appropriate emergency response procedures, contingency plans and resources commensurate with the risks to business activities.

5. Provide an effective occupational health and hygiene programme.

6. Take full account of health, safety and loss prevention considerations in projects, planning and decision making;

7. Treat local laws and regulaticins on health and safety as minimum standards to be improved upon wherever reasonably practicable;

8. Actively encourage the involvement of employees in the promotion of health and safety;

9. Encourage employees to accept individual ' responsibility for their own health and safety and for that of their colleagues, and to cooperate fully with company management in maintaining and improving health and safety standards;

Draft - 3

It is the policy of this Company (Name) to conduct its activities in a manner which ensures the healthful work environment and safety of its employees.

At all Company locations Local Management has the responsibility to ensure that all processes, equipment and facilities are designed, constructed, operated and maintained in a safe condition. It is also their responsibility to adhere to all applicable national, state and local government regulations. Cost considerations or the demands of production and operations, must not overshadow safety considerations.

It is the obligation of every employee to know and follow our safety rules and procedures, to teach what we know to others; to recognise unsafe acts and situations; to warn others of unsafe conditions; to react positively to emergency situations; to report promptly hazardous or unsafe practices and conditions to 'concerned Department Head; to protect the company property from loss or accidents and to perform his or her tasks to ensure the health and safety of themselves, fellow employees and the neighbouring communities.

Our Company is committed to achieving high standards for your personal safety and healthful work environment, as well as the safety of the communities where we operate. This type of safe and healthful work environment will be the result of complete cooperation, positive, prompt actions and a sincere commitment from all employees.

Draft-4

"Safely of person overrides all the production targets" - is the Health, Safety and Environment Policy of (Name of the Company).

To attain this, the Health,' Safety and Environment in the plants are safeguarded by the provision of:

1. Properly designed plants and machinery.
2. Effective use of safe working procedures, tools and equipment.
3. Meeting in all respects the applicable statutory requirements.
4. Clearly defined procedures for inspection, operation and emergency shutdown and their updation.
5. Continuous, systematic and micro level auditing - internal as well as external - of work procedures and practices.
6. Continuous and systematic education of Company's, Contractors' and Transporters' personnel for observing safe work practices.
7. A detailed investigation of all incidents including the minor ones and near-miss incidents followed by recommendations to avoid recurrence.
8. Analyse the findings or investigations of accidents in similar industry and take steps to prevent such accidents in the plants.
9. Keep abreast with the latest international codes, standards and practices.
10. Continuous monitoring of plant and ambient environment as well as of various effluents liquid, gas and solid - to maintain a clean and safe environment in and around the plants. .
11. Pre-employment and periodic medical check-ups of employees for early identification of occupational health hazards.

The policy so made should be circulated to top, middle and supervisory management and also to shop floor workers, apprentices and new entrants. Its enforcement should be effective and 'the top management must take full interest in it. It should be re-circulated at appropriate interval to redirect the attention.

Purchasing policy:

This should always consider safety aspect while placing order for machinery, vessels, tools, equipment, materials etc. A safety man should be charged with responsibility of checking plans and specifications of the items to be purchased. An approved list of items can be prepared for purchase department. The head of the department where the item is to be used should be consulted for his experience and requirement. Purchase orders should always specify that machinery be fully safeguarded and complying fully with the statutory requirements. Such type of purchase inquiry will encourage the machinery manufacturer or supplier to co-operate gladly with purchasers to solve their safety problems and to supply built-in-guards. Personal protective equipment should be purchased of good quality, reliability and standards and after consultation with the supervisor and the workers concerned. Inadequate protective equipment is worse than none, because it gives a wrong impression of safety.

The safety department should have good liaison with engineering and purchasing department. It should devise and enlist the safety standards that will guide the purchasing departments. Generally purchase people are cost conscious. They may buy the cheaper tools and equipment. Then they should be convinced of accident costs due to that. Safe mode of transport and handling material should also be suggested. Various codes, standards and statutory requirements should be considered. The purchase man should understand the hazard, accidents caused in past, legal or safety requirements, cost due to inferior quality, location or use of the machine and equipment etc. from the safety man.

6.5 Role of the Supervisors or Foremen:

A Supervisor or foreman (or forewoman) is a chief worker in charge of a group of workers and who exercises such control over them as delegated to him (her) by the management.

A supervisor is an important link or key-man between management and the workers. He is constant on the shop floor, more close to the workers, devoting more time in close observation of performance. He converts management's policy into action with the cooperation of workers. Management looks him as a shop floor manager in-charge of men, machines and materials and responsible for men's behaviours on jobs. Workers look him as their representative for the management. Workers like to give their opinions or complaints through supervisors. Management likes to influence workers' behaviour through supervisor and the workers like to gain first hand knowledge through supervisor. Management achieves the production targets through supervisor and workers achieve their targets, resources and facilities through supervisor. Therefore good supervisors are essential for effective implementation of management policy (including safety policy) on the shop floor.

A good supervisor performs the following functions:

1. Assurance of quality production within specified time and cost. He has to see quality, quantity, efficiency and effectiveness all at a time. This requires high skill.

2. Constant watch over safe conditions and actions for accident less production. He has to teach safety through his behaviour. His attitude is first reflected.

3. He has to see continuity in production. Therefore he manages to repair the machine and restart the job at the earliest possible.

4. He helps the workers in training them for their fobs and in solving their problems. He is useful in carrying out job safety analysis and on the job training.

5. He ensures safety through four major areas (1) Working machine/equipment and the job (2) Work area/environment or surrounding (3) Work methods, SOPs and actions and (4)- Work attitudes. For this purpose he inspects machine condition, job condition, surrounding situations, working environment, methods and worker's attitudes and tries to remove any defect if noticed. Checklist for this purpose may be very long but his eye should be the checklist. He establishes work methods, assigns jobs to persons, gives job instruction and maintains man-machine reaction safe.

6. For matter out of his control, he will immediately report to his higher officer. Meanwhile he makes temporary safety arrangements.

7. He pays attention on good maintenance of machines, materials, tools, etc. and also on good housekeeping and good health of the workers.

8. He reports all accidents and defects to the management and carries out their investigation for the purpose of stopping its recurrence.

9. He supplies proper protective equipment to workers and persuade to use them.

10. He observes and understands worker's difficulties. He observes physiological and psychological factors such as body movement, reaching-walking time and distance, weight, workload, environment, boredom, monotony and tries to find the solutions.

11. He has to carry out compliance of safety measures suggested by Safety Department, Factory Inspectorate and other authorities. Here he needs support from the management as well as workers.

12. He has to fill requisite production report, performance report, safety report and other records required. This requires his manifold personality.

Thus sympathetic and intelligent support of the able supervisor is essential to any safety programme. Proper training of supervisors in accident prevention is essential.

The status, responsibility and the degree of supervision of a supervisor varies according to the size and type of the industry, number of workers under control, position in hierarchy and extent of authority delegated. In a small factory a supervisor may enjoy wide power while in a big one where safety officer and workers safely committee exist, his role becomes limited to that extent.

6.6 Role of the Workers :

Who are most exposed to hazards? Who are nearer to the unguarded machines? Who handle the hazardous chemicals? Who lift the heavy materials? Who .face the dangerous machines, hazardous processes, unsafe conditions, situations and environment? Who mostly lose the life or get injury in accidents? No doubt, they are the workers only. They are the first victim of any accident. They are the sufferers of pain and all ill effects of occupation. Their families also suffer the losses. Occupational diseases and poisoning, minor or major injuries first touch them, because they are nearer to machines, hazards and environment. Therefore they must realise that any accident prevention work is in their interest and will save their lives. If they understand this fact, they will understand the need of safety and their role to promote and maintain safety.

The management should bring above facts to the worker's knowledge by accident figures, costs, compensation and company losses. Trade unions of workers should also teach the workers their safety duty and safe ways of working. **Workers' role should be explained to them as follows;**

1. Safety is worker's well-being and in their own interest. Their actions should be based on this.
2. Before starting the work, they should check all guards, fencing, safety devices and equipment in proper order and should always follow the safe methods of working. It should be checked after the closure of work also.
3. If safety guards and personal protective equipment are not provided, they should demand it through their supervisor or safety department.
4. Surrounding place should be kept clean, safe and without obstruction. "Safe Production is the best Production" and "Good housekeeping is always essential" should be their habit.
5. Wrong habits at work should be left.
6. They should take part in Safety Committee as expected under section 41 G of the Factories Act.

7. It is their right and duty under section 41 H of the Factories Act to warn about imminent danger in hazardous processes and to inform the occupier/manager and also the Factory Inspector.

8. They should analyse their own mistakes and failures tending to hazards and accidents and shodid rectify them with the help of supervisor or safety department.

9. Temptation to earn more by working overtime causes health hazards. Hurry, worry, short-cuts, chance-taking, over speed and over confidence also contribute accident causes. A shortcut may cut short. Therefore they should be avoided.

10. Sections 97 and III of the Factories Act draw attention toward offences by workers and their obligations. They are supposed to comply with the provisions of this Act, Rules and orders made there under imposing any duty or liability on them, otherwise, they are punishable.' Such duties cast upon them are :

    (a) They shall not wilfully interfere wither misuse any appliance, convenience or other thing provided for the purpose of securing health, safety or welfare of workers.

    (b) They shall not wilfully and without reasonable cause do anything likely to endanger themselves or others.

    (c) They shall not wilfully neglect to make use of any appliance or other thing provided for the purpose of securing health or safety of the workers and

    (d) They shall not refuse to undergo medical examinations for their health and safety.

11. They are responsible to their employer for their safe conduct of their work and safe upkeep or maintenance of machines and equipment.

12. They should not unduly interfere with the work of fellow workers and similarly should not allow fellow workers to interfere with their work. They .will exercise due care and good judgement in preventing accidents.

13. They should give their knowledge and experience in safety to new workers for safe working.

14. Through safety committee or union they should suggest their views in formulating safety rules and regulations. Thus they should give their • share to participate in safety management.

15. **Safety Representatives:** Some senior, experienced and selected workers can be assigned responsibilities to help supervisor in his work and to develop safe work methods, keep watch and to report hazards, correct and warn co-workers if they are found committing unsafe acts or breach of safety rules and to develop safety interest and behaviour among others, investigate small accidents and thus to act as a safety assistant to the supervisors. Such safety representative can then be easily promoted as supervisors. They can also join worker's safety committee or the joint safety committee.

6.7 Role of the Trade Union

Generally a trade union is a combination o work-people for collective bargaining on pay and conditions of employment, though its activities have expanded with the passage of time. Unions first grew up in UK and Eastern Europe and now they exist in each country. International trade unions also exist. In demands of better service conditions they should insist for safe and healthy working conditions also.

At present we see the trade union's role as mostly opposing management, raising demands for wages and allowances and launching cases in Labour Courts and elsewhere. With a few exceptions, hardly they do any work of teaching or educating for safe work practices. It is desirable that whatever may be their other activities; they should help the management in the joint task of safety by playing the role as under:

1. Checking and demanding for safe place, tools, machines, equipment, working conditions and environment for work.
2. Training and insisting their members to use and maintain guards, safety devices, protective equipment and to follow safe work practices. They can run the teaching classes in their offices in addition to the training by the management.
3. Always helping in maintaining safety in running the plant and safe closure of the plant in case of emergency. They should take lead in executing on-site emergency plan and the disaster control plan under the guidance of the management. In the matter of safety all problems should be solved by co-operation. Safety is not a field for quarrel. Safety equipment and conditions must be demanded but sabotage or any act endangering safety of plant, machinery, workers and others should not be committed. A helpful approach should be followed.
4. Checking for physical workloads, working hours, odd shifts, welfare facilities and statutory requirements for health, safety and welfare of workers and bringing them to the notice of the management and the authorities.
5. Actively participating in all safety campaigns, safety-day-programmes, seminars, publicity and every type of motivational safety movement.
6. Urging both management and members to measure up their responsibilities to safety drive and fulfil their obligations to each other so as to supplement the efforts.
7. Deputing their members on worker's safety committee or joint safety committee.
8. Sending their members for safety courses, seminars, and training classes.

6.8 Role of the Competent Persons:

By the Gujarat Factories (Amendment) Rules, 1995, rule 2-A was added from 15.02.95, regarding competent persons for following types of testing, examination and certification.

1. Structural stability of a factory building.
2. Dangerous machines (Rule 57 names such machines).
3. Lifts and Hoists.
4. Lifting machines and tackles.
5. Pressure plants (vessels and piping u/r 61.)
6. Dangerous fumes.
7. Ship building, repairs and breaking.
8. Ventilation and exhaust system.
9. Every work of engineering construction i.e. any building, tank, silo, scaffold, platform, chimney, bridge, supporting structure, retaining work or any similar structure (Rule 3C).
10. Centrifugal machines (Rule 54, Sch.5)
11. Power presses and their safety devices, (Rule 54, Sch.6).
12. Thermic fluid heaters (Rule 68D)
13. Ovens and Dryers (Rule 68 G)
14. Ventilation system in Asbestos manufacturing (Rule 102, Sch.17).
15. Instruments, safety devices, plant & equipment in chemical works (Rule 102, Sch.19).
16. Carbon disulphide plant (Rule 102, Sch.22).
17. Foundry operations (Rule 102, Sch.26).

Role of a 'Competent Analyst' is prescribed for ship building, repairing and breaking u/r 68 H and that of a special competent person (in-house) for a solvent extraction plant u/r 102, Sch.21.

B.E. and M.Sc. degrees in respective branch, 7 to 10 years experience and necessary facilities (equipment) are prescribed for a person or institution to apply for certificate of competency. Powers of the Chief Inspector are also prescribed.

Role of such competent persons in promoting and maintaining safety is most important for the management. By rules it is prescribed to examine and certify:

Duties and functions of the competent persons should be as under :

1 He should be a master of his subject.

2. He should have full facility of workshop, equipment, instruments etc, required for various tests to be carried out Equipment for extra heavy load testing, tensile testing, non-destructive testing, wind velocity meter, speedo-meter, metal quality, composition and thickness detector, hardness tester, various gas detection equipment, O_2/N_2 and hydrocarbon detector, noise meter, gauges/gadgets for testing-hoists and lifts, ' facilities for heat treatment, hydraulic testing and testing of effectiveness of the extraction systems for dusts, fumes, gas, vapours etc. should be available with him.

3 He should have qualified and experienced technical persons who know the use of above equipment.

4. He should have a library of technical books, safety codes and standards (viz. 18:2825, ASME code etc.).

5. He should have prescribed forms and certificates readily available, preferably computerised.

6. He should maintain the copies of certificates given to his customers, party wise, date wise and section wise.

7. He should have records/registers for the names, addresses and phone numbers of his customers, schedule of testing dates and a system of advance intimation of due dates of next testing to his customers.

8. He must report to the Chief Inspector of Factories and local inspector wherever it is statutorily required to do so.

9. He should keep a list of suppliers of safety standards and codes, safety devices, equipment, instruments etc.

10. He should guide properly and with details to the customers and the authorities as an expert and should be prompt for follow up action.

See Part 3.9 of Chapter-15 also.

6.9 Role of the Safety Specialists (Consultants or Professionals) :

The safety specialist or consultant is an outside expert agency whose services are hired by the management to guide or advise them on the matters of safety.

The safety specialist may be (a) An engineer to carry out tests and to suggest engineering controls (b) An occupational hygienist to suggest hygiene points (c) An occupational doctor to check, report and treat workers and work places for occupational health and (d) An industrial psychologist to study and guide for the psychological problems of the workers.

Having much experience and the latest knowledge on safety subjects, his role is important He can design and prepare plant layout, suggest safety guards and devices, protective equipment, safe working conditions, actions, methods, procedures, instruments, technique and all matters of statutory requirements. He can investigate accidents, analyse hazards and risks and furnish report of remedial measures. He may carry out special (e.g. Non statutory) tests for pressure vessels, lifting machines, illumination, noise, vibration, toxic exposure, utility services, control equipment and instruments and all safety aspects needed by the management. Thus he has got a vast and specialised field requiring high qualification, experience, insight and good power of observation, inspection, investigation and report-writing.

He recommends improvements, takes part in training and educating supervisors and workers, participates in safety meetings and seminars, acts as coordinator of safety work and as liaison officer with top management. Such safety specialists are rarely available, though it is a need of time. Experienced factory inspectors, safety officers and engineers can play good role of such safety specialist or consultant.

The safety professional's challenge is to accelerate and sustain use of safety techniques with the help of line managers. Therefore any safety professional must promote safety in diverse ways thereby getting the required attention and impact for the function within the organisation.

Some of .the ways in which can be reached to practising managers are : setting up experience sharing forums, projecting safety statistics to top management, empathising with "safety users" to get the right appliances, dissemination of accident stories, companywide consistent awareness programmes by use of multimedia and video, continuing education and use of positive reinforces to promote safe behaviour. The way safety is internalised is limited only by the safety professional’s imagination. Because safety is common sense, it may be taken for granted, therefore, one needs to bring energy and creativity to reinforce safety concepts in employees.

7 SAFETYORGANISATIONS

7.1 Types and Objectives (Need) :

Safety organisations include industrial management described so far, the governments and their labour or safety departments and the voluntary organisations such as International Labour, Organisation, National Safety Council, Central Labour Institute, State Labour Institute (viz. Mahatma Gandhi Labour Institute, at Ahmedabad), Gujarat Safety Council, Safety Chapters, Loss Prevention Associations, Safety Specialist or Consultancy Services and Safety Associations.

There are occupational health organisation, World Health Organisation and many other national and international organisation working for health, safety and welfare of people.

The objectives may vary depending upon the object, area, scope, team or personnel structure, qualification and experience, goals or targets and capacities of above organisations. Major difference is their jurisdiction, limitation and specialisation of safety work.

Some common objectives are :

1. To promote and maintain safety in all walks of life viz. industrial safety, road safety, home It safety etc.
2. To suggest safety rules for statutory amendments.
3. To conduct safety studies and seminars on major hazards and to publish reports for guidance.
4. To educate and train people for safety.
5. To run special safety services such as for engineering controls, health and hygiene, industrial psychology, testing laboratories, workshops for guards, design and performance, training and education, and various safety programmes.
6. To publish safely bulletins, booklets, posters and literature for general safety awareness and increasing knowledge.
7. To conduct safety courses for safety officers, supervisors, inspectors, workers and management.
8. To conduct safety competitions and to give' safety awards for encouragement.
9. To give requisite guidance on special safety problems of industries, government, workers, unions and associations, and
10. To carry out safety surveys, analysis, inspections, accident investigations and specific work studies for the purpose of detecting, directing and removing hazards. More such objectives can be available from the written constitutions of such organisations.

7.2 Role of the Organisations:

Role of three organizations is explained below:

7.2.1 Industrial Organisation's Role :

Part 5.2 and 6.3 of this Chapter have already described general and safety management's role. Some more information is given below:

An industrial management tries to achieve maximum productivity by its efficient organisation. Similarly in the field of occupational health and safety, it should try to achieve the goals of safety by reducing accident frequency and severity rates and risks and hazards tending to accidents. It should organise and integrate all efforts involving everyone from top management to the shop-floor workers. For this purpose it should (1) make a definite safety policy statement (2) divide and assign responsibilities (3) describe staff and line functions and duties of safety departments, safety committee, safety officer, supervisors, workers and others, (4) organise safety programmes which include inspection, audit, analysis, investigations, evaluation etc. (5) review the programmes and policy and make them updated and most effective based on timely requirements.

Essential elements (objectives) of a safety organisation are:

1. Management leadership.
2. Assignment of leadership.
3. Maintenance of safe working conditions and actions.
4. Establishment of safety education and training centre involving active participation of workers and unions.
5. Accident record system and management information system (MIS) with all safety statistics and costing.
6. Medical and first aid facility and
7. Acceptance of personal responsibility by employees.

Division of responsibilities is already explained in Part 6.3.10 of this Chapter. One model set-up (structure) is explained there. But this is variable from industry to industry. In a big company the resident manager takes the responsibility to develop effective programme for accident prevention or total loss control. Plant Superintendents are responsible for maintaining safe working conditions and practices in the areas under their jurisdiction. Department Heads and Supervisors are responsible for accident prevention in their departments and foremen (below supervisor) are responsible for accident prevention in their crews or a team (group) under their control. The Safety Director delegated by the Resident Manager has the responsibility to provide advice, guidance and any aid needed by the plant people. He decides for selection of protective equipment and safety devices, planning and holding safety meetings, devising forms and registers for - safety training, inspection, audit, checklist, safety sampling, job safety analysis, hazard analysis and different safety studies, posters, notes, notices, first-aid-training, fire-fighting training, hygiene training, and arranging periodical safety programmes for safety awareness, maintaining safety records and registers, keeping in touch with new safety developments, coordinating efforts of management and workers and rehearsal of on-site and off-site emergency plans.

7.2.2 The Government's Role :

Role of the Government in promoting and implementing safety is vital, because when voluntary efforts do not succeed, it is only the force of law which actuates people to move according to the desire of the Government. This is true from the ancient time. Because the older saying vxzr% prqjks osnk% i'pkn~ l'kjks/kuq% conveys the same meaning that "O men, follow the knowledge of four Vedas which are kept ahead, otherwise there is a bow with arrows behind". This indicates the need or fear of legal punishment in case of infringement of rules. Thus the legal enforcement is the primary duty of any Government organization.

Various safety statutes are enacted by Central and State Governments and number of amendments is being added to it. It is the duty of the Government to publish afresh all such Acts and Rules as early as possible for the knowledge of all public. It is also the duty to employ inspectors to check the legal compliance of such rules and to guide the management and workers for smooth implementation of all safety provisions and to institute legal actions if needed. Vast powers are now given to officers to seek strict compliance including issue of prohibiting order to stop manufacturing till the compliance is achieved. Sections 9, 10, 39, 40, 40A, 40B, 41, 41A, 41B, 41C, 41D, 41E, 41F, 41G, 41H, 87, 87A, 88, 88A, 89, 90, 91, 91A and various penal provisions under Chapter-X of the Factories Act describe wide powers of factory inspectors. Such powers are also provided under different state wise Factories Rules. This is a volume in itself and may be referred for details.

Powers of the Government were added in the Factory Act in 1987 regarding constitution of Site Appraisal Committee, compulsory disclosure of information, specific responsibility in relation to hazardous processes, appointment of Inquiry Committee, permissible limits of exposure of chemical and toxic substances, worker's participation in safety management, right of workers to warn about imminent danger and power to prohibit employment on account of serious hazard. Similar safety powers of government authorities are also available under other safety statutes (See Chapter 27 and 28 for this purpose).

Detailed instructions are listed for Inspectors of Factories. Their General Duties in short are:

1. To promote and enforce the uniform observance by occupiers and workers of the legal provisions of the Act and Rules.

2. To supply information and advice to employers, workers and their association concerning the best methods of complying with the legal provisions and the means of securing the best possible working conditions.

3. To bring to the notice of the competent authorities any defects or abuses not specifically covered by existing legal provisions and

4. To carry out such other duties as may be allotted to them.

Role of friend, philosopher and guide is also expected from them.

7.2.3 Role of the Voluntary Organisations :

International Labour Organisation (ILO) at Geneva carries out various functions to back up national action in occupational safety and health as follows:

No.	National action	ILO action
1	Legislation.	Conventions, Recommendations & advice on the drafting of legislation.
2	Regulation	Model codes, codes of practice, technical advice.
3	Technical and medical inspection.	Manuals, guides, technical publications, the CIS services.
4	Activities by safety and health institutes, training and information of specialists.	Fellowships, courses, symposia, congresses, technical advice and co-operation, the CIS services.

5	Worker's education.	Seminars, publications, audio-visual aids, the CIS services.

Details of such activities of the ILO can be had from its various publication, (see Reference No.5 at the end of this Chapter).

Central Labour Institute at Sion, Bombay-22, also carries out similar activities in India. Its ILO observation runs as "Examples of active specialised occupational safety and health institutes in Asia are to be found in India whose Central and Regional Labour Institutes are among the best of their kind in the world".

Some activities of the CLI are: (1) Safety education and training including (a) One year Post Diploma course in Industrial Safety for safety officers (b) Training of Factories Inspectors (c) ILO/ARPLA/ CLI courses (d) Training of foreign nationals (e) Safety training of executives, supervisors, workers and trade union leaders (f) Mobile safety exhibition and (g) Films and posters, (2) Research activities including (a) National study of accidents in the sheet metal working machinery and their safety features (b) Study of accidents in ferrous foundries (c) Ventilation studies (d) Noise studies (e) Textile studies etc. and (3) Consultancy projects. (4) It publishes various reports and publication.

National Safety Council sitting in the same building (now shifted in a new building in Navi Mumbai)- carries out the similar nation wide safety activities including safety seminars, publication of "Industrial safety chronicle" and plenty of safety literature.

Gujarat Safety Council at Vadodara and **Gandhi Labour Institute** at Ahmedabad are the state level safety institutions carrying out the similar activities. The GLI follows the CLI pattern and also conducts Post Diploma Course in Industrial Safety, various safety studies and training of employers, employees and inspectors.

Safety, Health and Environment (SHE) Association established at Bharuch in Gujarat unites safety officers, doctors and environment officers and carries out regular safety programmes including safety publication.

See Part 13.1 of Chapter-5 for names & addresses of 30 such organisations.

8 SAFETY DEPARTMENT

8.1 Size, Status and Functions of the Safety Department:

In foregoing Part 6.3.1 and 6.3.3 of this Chapter hierarchy of Safety Department from the Safety Board to Safety Committee, their general and scientific functions and their division of responsibilities are described. This constitutes a Safety Department. Its size and function varies with the size, nature and type of the factory with varying style of designations. There may or may not be Safety Board and may or may not be Safety Director. It may be headed by a Safety Manager or Chief Safety Officer or Safety Officer or Safety Superintendent, and he may be directly reportable to the General Manager as a Head of the Safety Department.

A system of making safety manager reportable to Personnel Manager or Public Relations Manager of Chief Engineer or Production Manager is not proper and not desirable as it keeps his status below to them.

By qualification (engineer with special diploma in safety), experience and expectation of the most important responsibility of health and safety of the whole factory and surrounding and of manifold functions (described in following paras) his status is not at all lower than these officers and therefore he should be positioned as independent Head of the Safety Department directly reportable to the top executive of the company. Unless and until his status is not so recognised, we shall not get the full advantage of this department and it is not matching with the safety policy declaring safety as the most desirable and lover-riding management function. Statutorily also it is required so.

Thirty years have been passed to the insertion of section 40B (with effect from 26.10.1976) for the I requirement of "Safety Officers" under the Factories Act 1948 and twenty three years have been passed to the ' Gujarat Safety Officers Duties, Qualification and Conditions of Service Rules, 1983 (with effect form 1-12-1983), but still many companies hesitate to give such full recognition and status to the safety officers disappointing them and thus impeding safety.

There are many functions for safety department and it will soon be realised if any management will go through the subjects and contents of this book. The subjects of safety are many requiring many duties, systematic planning and daily performance of regular checking, monitoring and training of workers. Actually the Safety Department must be equipped with sufficient staff and assistants to the Safety Manager or Officer for his many fold functions and for promotional opportunities of the safety men at lower cadre in this I department.

Functions and duties of' Safety Officers are discussed in the next part.

8.2 Safety Officer :

8.2.1 Need of the Safety Officer:

1. The mankind has always felt an age-old and permanent need of a saviour. The concept of God, Head of family. Head of a group and Head of society or people for their safety and protection indicates the basic need of a safety officer in its widest concept. The God is the greatest safety officer for all of us.

2. **Statutory need** is the base of requirement of an industrial Safety Officer. They are as follows:

    (a) Section 40B of the Factories Act 1948, creating the post of safety officer since 26.10.1976.
    (b) Notification No. KHR-566/FAC-107736875-M-1 dated 17.09.1983. Labour and Employment Dept., Sachivalaya, Gandhinagar, first published the Gujarat Safety Officers Duties, Qualifications and Conditions of Service Rules 1983, under the Factories Act 1948.
    (c) Notification No. KHR-728-FAC-1077-36875M-l dated 28.11.1983, above department appointed 1-12-1983 to be a date for the aforesaid Rules to come into force.
    (d) By the Notification No. KHR-294-FAC1085-1-130-M (1) dated 23.04.1985, the Government of Gujarat recognised (1) Diploma in Industrial Safety awarded, by the Technical Examination Board, Govt. of Gujarat and (2) similar Diploma by the Director of Technical Education of the States of Maharashtra, Tamil Nadu, West Bengal and Uttar Pradesh for the purposes of the Rule 3(ii) i.e. requisite qualifications under the Rules published as mentioned in para (b) above.
    (e) By the Notification No. GHR-2005-124FAC-2005-M (3) dated 4-12-2005 of the same Department; the Govt. of Gujarat adds the degree of MIHS (Master of Industrial Hygiene and Safety) of Sardar Patel University as a qualifying degree to become a Safety Officer.
    (f) By the Notification No. KHR-529-FAC1077-36875-M (1) dated 19.12.1985 of the same department, the Govt. of Gujarat specified the number (need) of safety officers as below:

No. of workers	No. of Safety Officers
1000 to 1500	1
1501 to 3000	2
3001 to 4500	3

4501 & above	4

(g) By Notification No. KHR-2003-57-FAC2003-2872-M(3) dtd 28-5-2004 of the same Department, the Govt. of Gujarat specified that each Major Accident Hazard (MAH) installation employing 100 or more workers shall employ one Safety Officer.

For definition of 'MAH installation' see section-2(g) of the Chemical Accidents (EPPR) Rules 1996.

(h) The syllabus is also prescribed by the Technical Examination Board, Gujarat for one year full time or two years part time course of Post Diploma in Industrial Safety. *This book is written to meet the requirements of this prescribed course, but, it contains many additional materials also so that the whole book is most useful to industries, safety officers, safety engineers, factory inspectors, managers, supervisors, workers and tJie public.*

3. Safety is the most important aspect. It must be given prime importance. There should be an exclusive officer for it. That's the Safety Officer.
4. Accidents and injuries must be prevented. The human life must be saved. These are the basic needs. For this the Safety Officer is required.
5. The Safety Science is much developed and widened. It has included many branches, techniques and many safety devices. All this needs a Safety Officer.
6. Factory Inspector has to look after so many factories and manifold duties. He cannot pay daily attention to each factory.
   A Safety Officer is expected to be a Factory Inspector for his own factory. He will keep a constant Watch for the safety in his factory.
7. Now-a-days machines, equipment, control measures, processes, process parameters and hazards are increased. This has increased the need of a safety officer.
8. Now-a-days more and more systems are developed. Work planning and work system are given more importance. Safety is also a work as well as a system and there should be a man to maintain it. This man should be a Safety Officer.
9. Major accidents in the world (like Bhopal) have emphasised the need for safety officer in a big or hazardous factory.
10. Two questions always need attention:
    1. WHY accidents (industrial losses) take place?
    2. HOW they can be prevented?

    Q.1 explains the causation analysis
    Q.2 explains the prevention techniques and safe work practices.

For constantly thinking of these two questions, their replies and to implement the safety measures, a safety officer is a must.

11. Use of chemicals is tremendously increased. This brings many hazards, occupational diseases, poisoning and health problems. To identify, minimise and prevent these increasing chemical hazards, need for a qualified and skilled safety officer is increased.

12. For appraisal of statistical' safety data and planning based upon it, a safety officer is required.

8.2.2 Safety Officers' Rules and their Role:

Summary of these Rules along with its last amendment in December 2005 is given below.

Gujarat Safety Officers Duties, Qualifications and Conditions of Service Rules, 1983:

Qualifications:

Rule-3 requires that basic qualification of a Safety Officer should be a degree or diploma in industrial safety recognised by the State Govt. Degree of MIHS (Master of Industrial Hygiene and Safety) of Sardar Patel University, Gujarat has also been recognised since 14-12-2005. He should have adequate knowledge of Gujarati language. **Without safety qualification, appointment as a Safety Officer shall not be continued after two years.**

Rule 3A and 3B are added by the amendment dated 30-11-2005 regarding appointment of Safety Officer and its procedure. Occupier is required to appoint number of Safety Officers as notified by the State government within six months from such notification. Advertisement in two local news papers is necessary before the appointment of a Safety Officer. A committee will select such officer from the applicants. The appointment will be notified to the Director, Industrial Safety and Health.

Filling up of Vacancy:

Rule-4 - Every vacancy in the post of a Safety Officer shall be forthwith notified to the Chief Inspector and shall be filled up within 3 months. Status:

Rule-5 regarding conditions of service states that where the number of Safety Officers exceeds, one of them shall be designated as the Chief Safety Officer and shall have status higher than that of others. The Chief Safety Officer shall be in overall control of the safety functions envisaged in rule 6 and the safety officers shall work under him.

The Chief Safety Officer or the. Safety Officer where only one safety officer is required shall be given the status of a Senior Executive and shall work directly under the control of the Chief Executive of the factory. All other safety officers shall be given the appropriate status to enable them to discharge their actions functions effectively. The Safety Officer shall be provided with adequate technical and secretariat staff and such equipments as is required by them to enable him to function effectively.

By the above mentioned amendment of 30-11-2005 sub rules (c), (d) and (e) are added requiring pay scale, allowances and other conditions of the Safety Officers same as those of other officers of equivalent status. Dismissal of Safety Officer is not possible without the consent of the Director, Industrial Safety laid Health. Thus his service is now protected.

Duties of a Safety Officer:

Rule 6 and 7 regarding duties or functions of Safety Officers are reproduced below:

Rule 6: Duties of Safety Officers: The duties of & safety officer shall be to advise and assist the factory management in the fulfilment of its obligations, statutory, or otherwise concerning prevention of personal injuries and maintaining a safe working environment. These duties shall include the following namely:

1. to advise the concerned departments in planning and organising measures necessary for the effective control of personal injuries;
2. to advise on safety aspects in all job studies, and to carry out detailed job safely studies of selected jobs;
3. to check and evaluate the effectiveness of the actions taken or proposed to be taken to prevent personal injuries;
4. to advise die purchasing of stores department in ensuring high quality and availability of personal protective equipment;
5. to advise on matters relating to carry out plant safety inspection;

6. to carry out plant safety inspection in order to observe the physical conditions of work and the work practices and procedures followed by workers and to render advice on measures to be adopted for removing the unsafe physical conditions and preventing unsafe actions by workers;
7. to render advice on matters related to reporting and investigation of industrial accidents and diseases;
8. to investigate selected accidents;
9. to investigate the dangerous occurrences reportable under rule 103 of the Gujarat Factories Rules, 1963 and in the cases of industrial diseases contracted by any of the workers employed in a factory reportable under rule 104 of the Gujarat Factories Rules, 1963;
10. to advise on the maintenance of such records, as are necessary relating to accidents, dangerous occurrences and industrial diseases;
11. to promote setting up of safety committees and act as an adviser and catalyst to such committee;
12. to organise an association with the concerned departments, campaigns, competitions, contests and other activities which will develop and maintain in the interest of the workers in establishing and maintaining safe conditions of work and procedure;
13. Design and conduct either independently or in collaboration with the training departments, suitable training and educational programme for the prevention of personal injuries.

Rule 7: No Safety Officer shall be required or permitted to do any work which is inconsistent with or to the detrimental performance of the duties prescribed in rule 6.

This means that 'duties other than safety' should not be given to Safety Officers.

Now let us see general duties (vital role) of the Safety Officer as under:

1. He shall carry out all statutory duties, as mentioned above. He should constantly check the strict compliance of all statutory safety provisions.

2. Where no statutory provisions are available, he should find out necessary safety rules from Indian Standards, Codes, literature, technology, experience and should try to implement them.

3. He should analyse all accidents, their causes and remedial measures and keep the abstract of it

4. He should suggest and implement the requisite safety measures, after appraisal of factual and statistical data.

5. He should carry out job safety" analysis and plant safety inspection, for the purpose of safety.

6. He should behave as a friend, philosopher and guide to workers and the general public. He should fit the unfit to survive.

7. He should always study various books, reported and publications on safety and should find out things necessary for him. (A list is given in Reference No.6 at the end of this Chapter). Constant increase in knowledge of safety is necessary for him.

8. He should design and implement newer and safer working conditions and working actions. Safer working conditions include all safety devices, engineering controls and process revisions, machine guarding and preventive measures. Safe working actions of all workers will be possible after deep observation, attention and training of them.

9. He should pay more attention on "duty" rather than on "right". This position is like a driver of a vehicle and his primary duty is to save life and property both. He has to work for total loss prevention.

10. He should train all his subordinates and workers for their safety duties. A programme of constant training and refresher course should be arranged. He should be a good lecturer on safety. He should utilise modern techniques for safety training, should display more safety posters, signs etc, should observe Safety Day (4th March, Dashera,Vishwakarma Day) etc.

11. He should consult factory inspector, other Govt. authorities on safety, his co-officers, other safety people and workers in case of need.

12. He should use better check-lists (of safety points) for his factory.

13. He should devise and rehearse a safety manual and Emergency and Disaster Plan for his factory to control abnormal situations.

14. He should carry out preventive and corrective maintenance with the help of maintenance staff. He should advise and follow periodical checking and testing schedules for this purpose. All safety and health test reports must be filled in only after due checking and testing. He should thoroughly study Form No.8, 9, 10, II, 2.0, 21, 2.6A, 37 etc. of GFR and also other statutory safety records and try to minimise the accident rates.

15. For chemical hazards, occupational health and hygiene, diseases and poisoning, much attention must be paid by him. He must take utmost care for Chemical Safety. He should well study and implement all aspects of this chemical safety to prevent health injuries due to chemicals, their storage and processes, vessels, equipment, exposures etc. He must consider all factors affecting health and safety viz. work, working methods, working conditions, working environment including ventilation, temperature, contamination etc., maladjustment to work, physical and mental strain from heavy and monotonous work, high speed, long working hours etc. These factors require proper study, engineering controls, preventive measures, health check-ups, workers education and training.

16. As an adviser to the management, he should give his advise based on his knowledge, experience and judgement regarding safety decisions. .

17. As a consultant to the line organisation he should give assistance in suggesting safety measures, interpretations of rules, codes, standards and regulations on safety.

18. As a coordinator and leader of the plant safety organisation, he has to provide enthusiasm and guidance to keep the organisation active and productive. He has to generate team-spirit, evaluate situations and solve the safety problems. He should work in close harmony and collaboration with line management and trade unions to ensure that no aspect of safety is neglected.

19. He must ensure that basic safety rules are followed in the design stage of building, plant, process, storage, handling etc. and in all working conditions, actions, usage of machinery, materials and protective equipment, accident investigation, inspections and audit, preparation of emergency instructions, training courses, records, safety incentive schemes etc.

20. His role is of manifold personalities. In addition to technical knowledge, he needs attitudes and qualifications of a good leader to make succeed all safety programmes.

8.2.3 Work Suggestions for Safety Officer :

1. Creation of independent office, staff, furniture, stationary, records etc.. for exclusive work of safety planning, design and administration.

2. Creation of class-room with black-board, teaching aid, safety postures, slogans, literature and effective display to carry out training for workers, supervisors, executives etc.

3. Creation of necessary registers, records, checklists, inspection-proforma, accident investigation proforma, maintenance-proforma, test-records etc. for the purpose of safety of plant, machinery, material, equipment, building etc.

4. Display of safety posters, slogans, maxims, banners, stickers near main gate, canteen, restroom, pay-office, other work-rooms and places where workers can easily see them. As far as possible, they should be in the worker's language.

5. Display of summary of monthly accidents just at the main-gate and some prominent places to bring them to the notice of all concerned. Monthly accidents should be classified as fatal, non-fatal, due to machinery and working conditions, due to worker's unsafe actions and place/shed/plant of serious accidents in the factory etc.

6. Preparation, rehearsal and updating of on-site and off-site emergency plan of the factory.

7. Conducting regular classes for one or two hours for all workers, supervisors, executives etc. by rotation and in small batches. Explain them the hazards, safety precautions and safety duty pertaining to the factory. Use effective teaching aide viz. video, safety films, pictures, computer etc.

8. Carry out regular rounds for plant safety inspection and risk analysis of all plants/ sheds/stores/places to check .safe and better working conditions in the factory.

9. To study unsafe actions of the workers causing more accidents and try to train them for removal of such actions.

10. To get the speedy compliance of the remarks of the factory inspectors, certifying surgeons and other safety authorities and to send the reply thereof.

11. To procure necessary safety equipment including personal protective and fire fighting equipment and to give training to the workers for their effective use.

12. To check all accidents, investigate them and to take necessary steps to minimise-them. To keep a proper record thereof.

13. To check compliance of the provisions of the Factories Act, Rules and other Safety Laws. To keep ready the prescribed forms under them.

14. To prepare monthly, half-yearly and yearly reports of safety work done and to submit them to the top executive of the factory and other authorities when asked for.

15. To carry out the duties prescribed under the Gujarat Safety Officers Rules 1983, and mentioned in foregoing Part 8.2.2 of this Chapter.

8.2.4 Attitudes of the Safety Officer :

To elaborate the role mentioned in foregoing para-20of Part 8.2.2, some philosophical and psychological attitudes and qualifications (qualities) necessary for a Safety Officer are given below:

1. Always search for knowledge. This is the basic tool. In our country the importance of knowledge is well recognised since ages :

fo}Roa p u`iRoap] uSo rqY;s dnkpu A
Lons’ks iwT;rs jktk] fo}ku loZ= iwT;rs AA

This states that the knowledgeable man is greater than a king because king is respected in his kingdom while the knowledgeable man is respected everywhere.

;L;ukfLr Lo;a izKk] 'kkL=a rL; djksfr fde~ A
ykspukH;ke~ foghuL;] niZ.k% fda dfj";fr AA

He who has no knowledge is not benefited by books, for, a mirror is of no use to him who has no eyes.

O;lukfu lfUr cgq’k%] O;lu};eso dsoya O;lue~ A
Fo/;kH;lua O;lua ;n~ ok gfjikn~lsou O;lue~ AA

Habits are many but only two are important a habit of learning or a habit of serving the feet of the God.

Now, how to acquire this knowledge? This is well explained by Gita as:

Rf}f} izf.kikrsu] ifjiz’usu lso;k A
Mins{;fUr rs Kkua] KkfuuLrRonf’kZu % AA

Know it by leaning down, interrogating and serving the Gums (men of knowledge) who will induct that knowledge into you.

2. Help of teacher/preacher is useful to interpret the knowledge.

xq: xksfoan nksuska [kM+s] fdldks ykxw ik; A
cfygkjh xq: vkidh] xksfoan fn;ks crk; AA

A teacher is greater than the God, because, it is the teacher who showed the God.

3. After acquiring the knowledge, work with full concentration. Example of Eklavya is eye-opening. Do everything carefully, nicely and whole-heartedly.

4. Make full use of the library. Read maximum books and reports on safety. Gain the working experience based on that knowledge.

5. Have tremendous self-confidence and work hard till the goal is reached. This is the only way to any success. What is the distance between success and failure ? "It is only three feet" was replied by a young American Engineer who drilled three feet more and received the goldmine. This distance is "only one stroke" as it was proved by Maharana Pratap in the famous fight of Haldighati. This distance is "only five minutes as the success was seen by Captain Nelson by waiting for five minutes only. The secret of success explained by Marshall Fox is that "simply determine not to be defeated". The cutting of ropes by Suryaji just before the capture of Sinhgadh proved the same thing. William the Conqueror said it "to burn your bridges". The escape of Shivaji from Agra fort became possible only due to his unparallel tremendous self-confidence.

6. After gaining knowledge and self-confidence as above, proceed to implement the knowledge of safety.

7. Insist more on engineering controls. Personal protective equipment should be the last resort.

Such attitudes are most useful to nil safety personnel for success in their work and life.

9 SAFETY PROGRAMME

9.1 Formulating the Programme:

Safety programme means a method employed by management to share and to assign responsibility for accident prevention and to ensure performance under that responsibility.

Four basic Elements (essential prerequisites) of Effective Safety Programme are:

1. Forceful continuous executive leadership.
2. Plant and equipment must be free from hazards.
3. Supervision must be competent and intensely safety minded and
4. Full co-operation ,in preventing accidents or health effects from all levels.

Of these the second element is more important as it is the main object of any safety programme.

9.2 Introducing and Developing the Programme :

Two purposes of any safety programme are to reduce hazard factor and to develop safe behaviour of all employees.

For the first purpose of reducing hazards the required activities are: (1) Planning for safe and clean technology (2) Safety in purchasing (3) Inspection (4) Job Safety (or hazard) Analysis and (5) Hazard investigation and (6) Prevention by remedial measures.

For the second purpose of developing safe behaviour the required activities are: (1) Placement (2) Training (3) Supervision (4) Education -and (5) Employee participation.

The techniques to detect unsafe behaviour are not so definite and clear-cut as those to detect unsafe conditions, because the human behaviour is not fixed like machines or materials. It is live and changing from time to time arid responding in different way due to different reaction. Chapter-3 explains this psychology of human behaviour. Therefore a programme of developing and maintaining safe "behaviour includes selected placement for a selected worker, education, training and supervision allowing participants in safety committee, advertising and publicity of safety rules and motivational slogans. Perhaps on-the job safety training by personal contact is more effective. Unsafe actions should be corrected till full rectification.

9.3 Evaluating and Reviewing the Programme :

For full success of any safety programme it should be evaluated and reviewed from time to time. Chauler-19 suggests such appraisal methods. The appraisal keeps the performance up to the mark. Careful watch for safe performance is necessary. The top executive can set suitable goals and means of gauging improvements in human behaviours.

The benefits of value measurement of safety activity/programme are: (1) It conveys to the top management the status of safety efforts and safety development (2) It enables the safety professional to promote effective loss prevention measures (3) By comparing weighted score from year to year, the progress is monitored.

Methodology: Various criteria are selected for evaluation. Weighted values are provided to each sub-activity under each criterion. This way it can be known in advance what is going to be measured and how the results will be compared with the previous results. The evaluator should have good grasp of the operations and the expected standard of the activity.

Main Criteria or area for evaluation are : (1) Organisation and administration (2) Industrial hazards control (3) Fire control (4) Industrial hygiene and health (5) Supervisory participation, motivation and training and (6) Accident investigation, statistics and reporting procedure. Each of these criteria are subdivided into 4 to 6 sub-criteria and rating (marking) is given to each of them as poor, fair, good and excellent. One model rating form used by Dow Chemical Co. (USA) is given in Table-5, Chapter-32.

10 SAFETY EDUCATION AND TRAINING

10.1 Definitions :

R. P. Blake has explained the difference of education and training. He says, "Education deals with developing the mind, broadening knowledge and understanding. Education in a specific subject means acquisition of broad and thorough knowledge m .that subject. Training deals with the development of skill in performance. In industry it refers to the skilled trades as applied to safety. Education and training are not completely separable, each participates to some extent of the nature of th» other. Safety Education is for developing safety mindedness - a vivid awareness of the importance and correcting conditions and practices that might lead to injury. Safety training is for developing the worker's skill in the use of safe work techniques and practices. It is described as a detailed extension of the educational safety programme applied to specific occupation, processes, jobs or activities".

Oatey (1970) defined training as "Any activity which deliberately attempts to improve a person's skill at task".

Hesseling (1971) defined it as a sequence of experiences or opportunities designed to modify behaviour in order to attain a stated objective.

Hamblin (1974) defined it as "Any activity which deliberately attempts to unprove a person's skill on a job as opposed to education which is mainly concerned with personal development and not related directly to the job."

McCormic & llegen (1987) opined that the crux of training is that "It is the management of learning. It is an organised procedure which brings about a semi-permanent change in behaviour for a definite purpose. When this definite purpose is "Safety", it defines "Safety Training".

A functional definition of training is the acquisition of concepts, theories, knowledge, skills and attitudes so that employees are equipped to perform competently in their present or future jobs resulting in increase of efficiency of the organisation as well as their own job satisfaction.

On the other hand "development" is defined as lie application of acquired knowledge, theories, skills and attitudes to the job for increasing organisational effectiveness.

Training is one way to develop a more flexible rand efficient work force. Modern technological change is a driving force behind today's training, especially in technical areas. Modern technology also brings hazards and suggests remedial measures. Therefore safety training is becoming more and more essential to develop a skilled and motivated work force to understand and identify hazards, to find out and apply the appropriate safety measures to maintain safe working conditions-and actions.

Safety Training is an extension of educational safety programme applied to specific activities or process viz. industrial activities, work on machines, .chemicals etc.

10.2 Elements of Training Cycle :

As per OSHA (Occupational Safety & Health Act)'s training guidelines, seven chronological steps are suggested to complete a training cycle. These are the basic elements of any safety training programme. Fig. 6.14 shows them in a cyclic order.

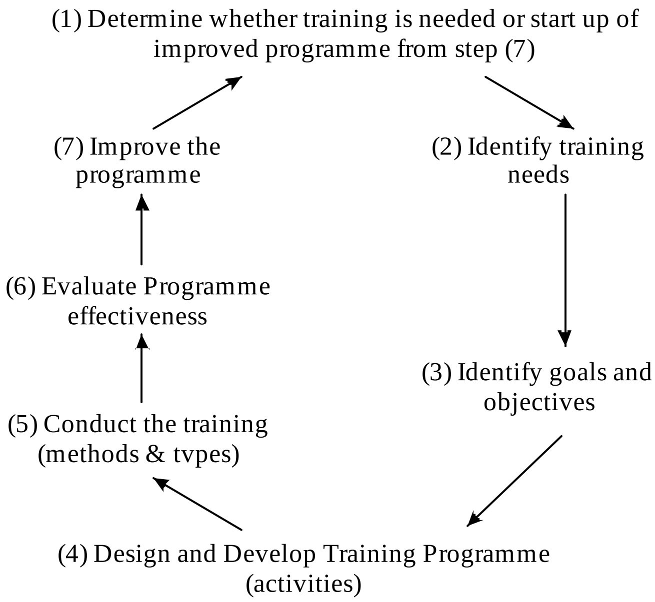

Fig 6.14 Training cycle

These steps are explained as under:

1. **Determine if training is needed** - The first step is to determine whether a problem can be solved by training. All skill deficiencies are not solvable through training and some other tool may be required. This step includes need of any improved (revised) training programme.

2. **Identify training needs** - Analyse the worker's duties and what he or she needs to perform the job more skilfully and safely.

3. **Identify goals and objectives** -A list of specific job knowledge and skill deficiency derived from Step-2, will fell employers what workers should do, do better or stop doing.

4. **Design & Develop training programme** - After listing precise objectives and goals, learning (training) activities must be identified and described. Type of training will be decided based on the training resources available to the employer, the kind of knowledge or skills to be learned and whether the learning should be oriented towards physical skill or mental attitudes.

5. **Conduct the training** - Now the training programme should be conducted by (a) providing overviews of the material to be learned and (b) relating each specific item of knowledge or skill to the worker's goals, interests or experience to be learned.

6. **Evaluate programme effectiveness** - By knowing trainee's opinion, supervisor's observation, work place improvement, hazard reduction, performance improvement etc., it should be checked whether the training has accomplished its goals.

7. **Improve the programme** - Based on feedback from the workers, supervisors etc., and from evaluation and observing the gap, the training programme should be improved (revised) as per need.

10.3 Assessment of Training Needs :

The first step of any training process (cycle) is to be sure about the needs. Following four questions (approaches) should be considered:

1. Does an actual or potential performance discrepancy exist ? (viz. unsafe conditions, actions, efficiency).
2. Is it important to the organisation ? (viz. in reduction of cost of accident, hazards, losses etc.).
3. Is it important to the employees ? (viz. basic training to new employees, refresher course for old employees, more mistakes by workers, more accidents to them).
4. Is it correctable through training? (If yes, then only the training becomes useful and cost effective.

General training needs are assessed from following grounds:

1. New employees are not very clear about job description. Therefore training is essentially required for them.
2. Old employees require knowledge of new topics, new technology, process revision, new methods and forgotten old items. Training for emergency preparedness, safety audit, fire fighting, hazard detection etc. are also necessary for them.
3. Change of position due to promotion or transfer. New position may require training.
4. Technological changes in the organisation. Addition of new material, machine, method, process, equipment etc. create need of training.
5. To make a person more versatile to do more than one job (safety supervision, accident analysis and computer data feeding).
6. When performance, productivity and efficiency fall down at any level, training may improve them.
7. Supervisors/foremen feel need of training for workers working under them.
8. Records of production, turnover, accidents, absenteeism, rejects, errors, wastes point out areas of training.

The safety training programme is generally needed for all the times as an induction or introductory course or a refresher or ongoing course but is specifically needed when

1. New employees are recruited
2. New plant, material, process or equipment are introduced
3. When safety procedures are evolved or updated
4. New information of hazard is received
5. Safety performance needs to be improved
6. The accident rates are increased
7. Labour turnover is increased and
8. Excessive waste, rejects and scrap are noticed.

Under sections 7A (2) (c) and III A (ii) of the Factories Act new provisions are added for training to ensure the health and safety of all workers at work. This is statutorily required as under.

Every worker shall have the right to get trained within the factory or at a training centre or institute duly approved by the Chief Inspector, where training is imparted for worker's health and safety at work.

Four-approaches are suggested to determine safety training needs as under:

No.	Approach	Content
1.	Common concepts approach.	Assess own situation / requirement based on real need. Specific result oriented programme instead of general knowledge.
2.	Safety need analysis approach.	Job Safety Risk Analysis useful. Gap between job requirement knowledge and employee knowledge suggests training need.
3.	Problem Identification approach.	From employee's performance appraisal report, his need can be assessed and fulfilled by personal coaching, instructing, guiding etc.
4.	Organisational Safety Survey approach.	Classify and analyse accident and calculate and compare performance rates. Conduct hazard survey. Study existing safety measures, interview key personnel and arrive at needs and deciding priorities.

10.4 Objectives of Training:

Training cannot and should not be started without any pre-decided objective. Training without objective (purpose) or for the sake of training is of no use and becomes wasteful activity. Training need must be assessed first and from that the objective(s) should be specified as under :

1. Transmitting information about policy, product, services, accident causes and remedial measures, new process, methods and technology or the company itself.
2. Developing skill for safe behaviour and to work efficiently.
3. Modifying attitudes more favourable to safety, production, co-operation, discipline etc.
4. To give a worker a new, necessary and broader view point of his safety responsibility
5. To explain him potential hazards of unsafe working conditions, actions, environment and safe views to prevent them and
6. To increase his safety consciousness, perception of danger, knowledge, experience, confidence, responsibility and ability in safe performance.

10.5 Techniques (Procedure) of Training: Competence Building Technique (CBT)

The concept or basic object of any training is to generate or build competence in participants (workers). Only knowledge is not sufficient. Knowledge alone cannot give competence or confidence of safe or successful working. Knowledge should be put into practice by necessary training. Training shows the practical part of knowledge and generates competence of work gradually.

Competence in safe working is necessary. Due to advancement in technology, new processes, new equipment, modification or changes, training is always required to become familiar with tins. Therefore, safety is an online function. It should not end with any slogan, suggestion, award or safety day celebration.

It should be considered as' a part of continuous or ongoing activities. For this purpose, induction training and refresher training are organized. Effective communication system should be utilized. Role of multimedia and computers should be utilized. Safety films, pictures, hazard points, accident case studies etc should be shown and explained during training.

See Part 10.8 to 10.14 for different roles, teaching aids, and techniques of success training.

A good safety training programme contains following steps:

1. Determine safety training needs and priorities by four approaches stated in Part 10.3
2. Design training to meet the needs. The steps are: (a) Assess training requirements (b) Determine training contents (c) Decide training methods and aids (d) Organise training content (e) Formulate training plan and (f) Decide evaluations measures.
3. Implement training process. The steps are: (a) Discuss with company officials (b) Decide administrative aspects and time schedule of training (c) Execute (give) training to the decided trainees (d) Monitor the programme (e) Conduct review of safety training and (f) Have follow up of trainees.

Techniques of training are generally the "training methods" which are discussed in detail in Part-10.7 following. All these training (teaching) methods are broadly classified into two types of techniques known as off-the-job techniques and on-the-job techniques:

(A) Off-the-job training techniques :

No.	Category	Techniques (methods)
1.	Information presentation techniques (less involvement of trainee).	Reading list, Correspondence course, Films, Lecture, Panel discussion, Programmed or Computer based instruction.
2.	Information processing techniques (trainees are involved).	Conference or discussion group, T (training) group.
3.	Simulation techniques (experiment or practice).	Incident / case, role playing, In-basket, Vestibule, Mock-up, Business game.

(B) On-the job training techniques :

No.	Category	Techniques (methods)
1.	Actual job assignment.	Coaching, Job instruction training (JIT).
2.	Temporary job assignment.	Special assignment on job, committee, project etc. job rotation through predetermined set of jobs to provide exposure to different part of the organisation.

10.6 Design and Development of Training Programme :

Any training programme should be designed for its specific purpose. Design and development of safety training programme need systematic job safety or risk analysis. For steps (detail) of such analysis see Part 1.5 and 4.3 of Chapter-19.

Following general points are useful in designing and developing any training programme.

1. Motivation should be the first condition of any type of training.
2. Number of lessons and content to teach should be well designed beforehand. Steps or sequence of topics should be decided.

3. The amount to be taught in an unit (period) should not be too large or too small.
4. An objective of the training should be decided and the training process should move toward it. The training procedure should be developed.' A list of training aids should be prepared.
5. The task to be performed should not be descril)ed only but it should be demonstrated in actual or simulated conditions. "Doing" is important than mere "Hearing" or "Seeing". Practice makes perfect.
6. The demonstration (by teacher) should be followed by the learner (trainee) as soon as possible before' he forgets it. The teacher should be given feedback or knowledge of results.
7. Questions of learners should be properly replied and discussed at all stages (steps).
8. Ample practice opportunity should be provided and practice encouraged.
9. Frequent and accurate knowledge with examples, pictures, practical etc., speeds up learning rate and motivation.

10. The training should be taken to the point of goal and not be left unfinished.
11. Effectiveness of the training should be evaluated and conclusion be drawn to revise (improve) the training programme and it should be followed in the next cycle.

According to Gagne, any human task (including safety) can be analysed into a set of component tasks (Job Safety Analysis, Part 1.5, Chapter-19). The basic design of any training should consist:

1. Identifying the component tasks of a final performance.
2. Ensuring (in training) that each of these tasks is fully achieved or mastered by the learner.
3. Arranging the training of the task components in such a way that there will be positive transfer from learning of one to another.

The design work may be done by specially designated training professionals, especially for programs to be offered several times or left to individual instructors.

Main design steps include (1) Setting instructional objectives (2) Determining programme content.. and (3) Selecting instructional techniques for off-the-job and on-the-job training.

10.7 Training Methods and Strategies :

Aspects and Goals : The training methods have two aspects:

1. Theoretical or formal in the classroom and
2. Practical or informal in the job place.

There are two basic goals :

1. To explain the worker to know the job and to do it correctly and
2. To be certain that he knows how to do it ' correctly.

Steps: Any training method should have following steps:

1. Lay down the objective of the training programme.
2. Prepare the training programme.
3. Brief the trainee.
4. Use audio visual aids where appropriate.
5. Review the contents and
6. Follow lip with trainees when the programme is completed.

Effects of Methods : Effectiveness of different training methods is given by Bird as follows:

A trainee tends to remember 1-0% of what he reads, 20% of what he hears, 3Q% of what he sees, 50% of what he sees and hears, 70% of what he sees as he talks and 90% of what he says as he does a thing. This percentage is variable depending upon one's memory power, intelligence, grasping, understanding, susceptibility and interest in the subject. It also depends upon the explanation power. These factors can be developed by education and training. Speaking, writing, involving and doing are the most effective exercises to digest any subject.

Types of Methods : Some usual methods are: Lecture method, discussion method, case study, role play, project work, programmed instruction, on-the-job instruction, training aids, fault analysis, algorithm as an aid to fault analysis, fault tree analysis, drill, demonstration, panel or group discussion, meeting, simulation, pictures and posters, films and closed circuit television, filmstrips and slides, projectors and microphones, charts, boards, and working models, checklists, exercise, rehearsal and use of press and other mass media.

Thus methods are many from old to the ultramodern. Which method is the best? No one method can be named. Appropriate method should be selected depending upon the size, age and experience of the group, the amount of material, type of presentation necessary and time and money available. Selection of method requires skill and experience. Result of effectiveness depends upon it. Therefore make the best choice of the method and apply it successfully. Display of relevant safety posters at workplaces contribute much without saying.

Some common methods in use are mentioned below:

1. **Lecture Method :** Oldest and most basic method. Well planned lectures can cover a large amount of information in a short time. More useful when participants are more, or their involvement is less required.

2. **Discussion Method :** Useful with small number of people in a group. The trainer acts in a limited way as a scene setter or referee encouraging participants to speak out. The two way communication moves toward objectives. Participants are more attentive, active and don't feel boredom.

3. **Case-study Method :** Accident case study is presented explaining how an actual accident happened or an imaginary accident can happen. Causation analysis and remedial measures can be discussed by questions and answers. Good pictures are more useful to explain the situation effectively. See Chapter-30 for accident case study.

4. **Role playing method :** It is a form of learning by doing but in a simulated situation. Trainees are given 'a situation like in case-study method but instead of just discussing it they resolve the problem by acting out the roles of the people involved. Here extrovert trainees show their skill but introvert or shy trainees unused to such situation get embarrassed.

5. **Business Games Method:** More useful for business people and skill required for safety attitude or inspection in buying/selling items which are more safe or with the details of safety.

6. **Sending at training Centres :** Institutes, seminars, workshops, special courses etc. utilises external resources for required training.

7. **Job instruction training:** Useful to train supervisors who in turn train the employees. Job instruction training (JTT) involves four steps (1) Preparing the trainee (2) Demonstrating the job (3) Having the trainee performed the job and (4) Checking frequently the trainee's performance. All new job assignments should be preceded by on-the-job training. Each step of job safety analysis (JSA) is explained with hazard, safe procedure and use of safety equipment. Use of guards and controls are also explained.

8. **Programmed instructions :** Programmed instructions are given in a book form. A trainee learns it, answers the question or solves the problem. The system has mechanism of learning-checking and relearning.

9. **Project work :** Project writing is given to trainees. They apply their knowledge to practical situations.

10. **Other methods :** Job rotation, committed assignments, HRD training, sensitivity training, creativity training, in-basket training etc. are other specific methods.

10.8 Types of Safety Training :

Types of safety training are formal and informal. Formal training may be general or specific.

General Training includes -

1. Induction courses for new employees.
2. On-going safety training.
3. Safety representative training.
4. Supervisory training.
5. Senior/ middle management training and
6. Directors training.

Specific Training includes -

1. Safety system of work for particular operations where the potential hazard is high and guarding is not feasible.
2. First aid training.
3. Specific items of plant or equipment.
4. Use of protective equipment.
5. Fire precautions.
6. Safety inspections.
7. Change of job for which a worker is not trained.
8. Role of workers in emergency planning.
9. Techniques of safety audit, Hazop, Hazan, FTA, ETA etc.
10. Safety permit system.

Some details are given below:

1. **Orientation or Induction Training :** It is obvious that new employees may not be knowing much about the factory they joined, its safety policy, specific raw-materials, their characteristics, processes, methods, pollution control, health check-ups, role in emergency planning, first-aid, fire fighting, use of personal protective equipment, accident record, hazards of their work, remedial measures and workplace monitoring etc. Therefore it is always useful to design training on such subjects for the new employees. This basic knowledge builds their confidence, skill and interest towards the work and the company both. See also following Part 10.9 - for "Training to New Workers".

2. **Apprenticeship Training :** A learner who has just completed his school or college education or is still undergoing it and agrees to work as a trainee or apprentice or employed under the Apprenticeship Act as an statutory requirement, is given this type of training. It is a combination of on the job and off-the-job training taking the strengths of both. Intention is to show him the practical or applied part fitting to his type of education.

3. **On-the-job training** is practical in nature and generally takes place on the job. Such job contact sessions may involve individual on one to one basis with the supervisor training an operator for the work he has to carry out.

First the supervisors are trained for this purpose showing them the job safety or risk analysis. Then in turn they train the employees mostly new. It imparts necessary skill for the job involving worker to do the job systematically and safely. Injury to the trainee or the job is possible due to normal mistake of the trainee. Therefore its usage is limited to situations where mistakes can be tolerated. Airline pilots and Surgeons are allowed on the job practice only after their skills have been sharply honed using off the job simulation techniques.

Some methods used in this type of training are coaching (personal attention), job instruction training (JIT), special assignment and job rotation.

It is supervisor's or training instructor's responsibility to train the employees under him for safe methods, machine guarding, identification of hazards in each step and its remedial measure, need and use of safety equipment, avoidance of shortcuts, hasty actions, overconfidence etc.

4. **Off-the-job training :** All types except on-the-job are called off-the-job training. It includes classroom or lecture method, audio-visual, film, reading list, books, correspondence course, panel discussion, conference or discussion group, T-(training) group, computer based instruction, case study, role playing, in-basket, vestibule, mock-up, business game etc. and explained as "training methods" earlier.

5. **Vestibule Training:** It is an approach between on-the-job and off-the-job training and used when the job is dangerous and can harm the trainee if taught on the job. The training takes place away from the actual work place but the equipment and procedure to be followed are similar to be used on-the-job.

6. **Individual and Team Simulations:** Equipment and procedures that duplicate actual equipment and work conditions as closely as possible are known as "simulators" e.g. set up for training pilots and astronauts. When economic or human costs of error are very high, this type of training is safe and cost effective.

7. **Team Training:** It is required to increase coordination and co-operation amongst team members and make them realise that their behaviour may help or hinder co-workers from performing effectively.

8. **Individualised or Programmed Instructions:** This is a technique to supply instruction through printed material or machines. Safety instructions by placard, slides, banners, notices, boards, film, transparencies, check list etc. are useful. It eliminates need for an instructor and trainees can learn when and where they choose. They do not have to be assembled at one place and one time. This type is useful where a number of trainees cannot be spared from their duties simultaneously.

9. **Modern methods of Training:** It is a derivative of programmed instruction and utilises computer as medium of instructions. A computer is fed with the entire programme of presenting material asking questions and evaluating responses.

The computer adjusts instructions according to the learner's abilities, prior'knowledge and his replies to computer's questions.

It is like a private tuition by a computer as teacher who has full command of the subject and who never gets tired of repeating replies. It gives immediate feedback without sarcasm, anger or error. The disadvantage is the cost of computers and programs if they are need in bulk to supply individually.

See Part 10.13 for training aids.

10. **Other types:** Types are also classified as technical training, HRD training, safety training, productivity or creativity training, voice training, ISO training, computer training, customer training, supervisor's training, training for training etc.

Now-a-days importance of training is widely accepted at all levels. Type should be selected best fitting to our need and budget.

10.9 Training of Workers and Supervisors :

Safety training should begin with every new worker and continue till he is in the service. Successive steps may be increased. Japanese system of weekly training (one day .in each week for training) is the best example of such training. The type of training, frequency, content and trainer may vary according to the need and type of industry.

Training to New Workers :

Safety training should be given to all new workers, irrespective of previous experience. He should be taught:

1. Safety Policy, rules and practices of the company. Provisions for safety committee.
2. Worker's duties and rights under the Factories Act and other safety statutes.
3. Emergency signals and their meanings.
4. Observance of warning signs and symbols.
5. Location of means of access, phones, fire alarm and extinguishers, emergency exits and procedure, first-aid and ambulance room, safety office, assembly points etc.
6. Types of protective equipment, their need and practice to wear them.
7. Types of hazards of his job and safeguards provided and to be maintained.
8. Safe practice and full job instruction for his job.
9. Codes and standards to be followed.
10. Records to be filled in.
11. Means of reporting hazards, absence of guard or defective equipment.
12. Need for good housekeeping.
13. Types of frequent accidents in his plant and means to avoid them.
14. Not performing any new job or machine without first learning from the supervisor.
15. Seeking medical assistance in case of any type of injury and reporting it to the supervisor.

Even older and experienced workers need periodical job safety training and new knowledge to them. Safety meetings and .various types of safety refresher courses should be arranged to increase their job-training and safety performance.

Training to Supervisors:

Training to supervisors is most important because safety and production control are associated with supervisory functions and it is their main duty to prevent accidents. Objectives of safety training to supervisors include

1. To explain them their principal responsibilities of establishing work methods, giving job instruction, assigning people to job, supervising people at work and maintaining good housekeeping, plant and equipment.
2. To acquaint them with the company's safety policy, rules and practices.
3. To emphasise that accident investigation work is solely for prevention purpose and not for fixing blame.
4. To establish their status of a key-man for safety and production.
5. Ways and means to maintain safe conditions and actions.
6. Special information on accident causes and methods of prevention, particularly in their areas "of work. Case studies of actual accidents.
7. Job instructions for safely, supervising for safety, accident reporting, investigation and. record writing, job safety and risk analysis and group meetings for safety etc.
8. Ways and means of job training to workers and training aids.
9. How to participate in planning of safety programme and safety committee.
10. Solving of supervisory problems. The steps are :
    (a) Identify the problems.
    (b) Find and verify the reason for the existence of the problem.
    (c) Select the appropriate remedy and apply the remedy.

Some supervisory problems are stated below :

Kinds of Supervisory Problems :

1. *Work Problems*: (1) Error of commission or omission (2) Insufficient work (3) Poor work quality (4) Breakage, wastage, spoilage etc. (5) Improper methods, tools, equipment etc.
2. *Procedure, Rules etc.:* (1) Violation of rules (2) Failure to report facts (3) Abuse of privileges (4) Failure to maintain premises, tools etc. (5) Play, gossip, loafing etc.
3. *Additional Problems:* (1) Direct refusal or insubordination (2) Assumption of unwanted authority (3) Loose talk (4) Ridicule of criticism of the company (5) Creating disturbance, noise etc.
4. *Personal Problems:* (1) Dissatisfaction, wages, treatment, unhappiness (2) Chronic tardiness -or absence (3) Outside, home, social situations (4) Demands for premature promotion (5) Trivial tale bearing.

Reasons and Remedies of Supervisory Problems :

Reasons for existence of problems: (1) Lack of skill (2) Insufficiently informed, misunderstands (3) Not convinced-indecision (4) Finds standard procedure difficult, awkward etc. (5) Spare, light, tools etc. inadequate, unsafe etc. (6) Physically unsuited (7) Personal characteristics unsuited.

Remedies: (1) Engineering or process revision (2) Persuasion and appeal (3) Personnel adjustment (Placing and medical treatment (4) Psychological treatment and (5) Discipline.

10.10 Individual v/s Mass Training :

Both are necessary. When common things are to be taught, mass training saves the time and therefore it is mostly utilised. Class-room or workshop training, lectures and demonstration, seminars, tours, radio, TV and all audio-visual methods are invented for effective mass trailing. Individual training is on-the-job training and it is mostly given by a supervisor to a new worker or wherever necessary at the work places. Handling tool or material, setting and performing job, art of repairing, wearing, and using personal protective equipment, using fire extinguishers, gas-detectors and other safety -devices, calibrating, testing and examination, driving, report writing etc. need individual training for good practice.

Disadvantages of mass training are: (1) Individual attention is not possible and it is not equally utilised by all (2) It is hasty (3) Things which are to be seen at the situation cannot be explained properly (4) Use of mass training aids requires expenditure.

Disadvantages of individual training are (1) It requires much time, patience and skill (2) All are not trained at a time (3) Groups cannot be trained (4) Advantage of expert's teaching or seminar is not possible for an individual. Its main advantages are: it is cheap, builds personal relation and provides in depth training.-

10.11 Need for Re-training (refresher course):

This is also felt necessary to refresh the memory and maintains skill and ability for continuous good performance. Generally higher officers and top executives are more benefited by periodical re-training, because owing to their attention divided on multiple administrative and technical matters their chances of forgetting particular details are more.

When it is felt that a worker has started making mistakes or accidents, it indicates need of re-training. Before giving re-training facts of past training should be known for guidance.

10.12 Integration of Safety Training with Job Training :

This is necessary to increase overall knowledge of doing the job safely. With specific subjects if some safety subjects are integrated, it promotes safety in better ways. In a big concern the manager of training and the safety manager should work together in the planning of various kinds of training programmes. Generally safety training should be job oriented to bring perfection in job performance. If safety training is not so integrated, it is of little use. Therefore at the planning level such integration should be designed to extend the maximum benefit of safety training. Safety should be part and parcel of the job or industrial activity and such integration should be -like a chemical compound which is deferred from mixture.

Curriculum for degree, diploma and craftsman courses in engineering must contain more and more safety subjects at teaching and training levels.

10.13 Types of Training Aids :

Following aids are useful in training :

1. Black boards, magnetic boards and flannel boards.
2. Charts, drawings and posters.
3. Slides, filmstrips, transparencies and overhead projector.
4. Printed material like books, manuals, handouts etc.
5. TV and Movies.
6. Scale, models, mock-ups, training devices and simulators.
7. Computers, Software (e.g. power point, page maker, graphic design and display etc.), CDs, LCD projector etc.

Training or teaching aid should be selected judiciously to make learning interesting, meaningful and without boredom or monotony. Just after lunch interval in the afternoon, film may be more effective than mere lecture. Where machines and equipment are used as aid, they should be safe and clean and their safety and ergonomic aspect should also be explained.

10.14 Evaluation & Reviewing of Training Programme :

An evaluation i.e. measurement of effectiveness or result of the training programme conducted, is useful in reviewing .the programme content, method, aid and redesigning the programme as per feedback for improvement. An effective training programme should show;

1. Increase in quantity and quality of production.
2. Increase in production rate.
3. Increase in knowledge, skill and ability about job performance.
4. Increase in job satisfaction and motivation.
5. Decrease in accident rate.
6. Decrease in production time, breakage or use of consumable items.
7. Decrease in absenteeism.
8. Decrease in labour turnover.
9. Decrease in job turnover.
10. Decrease in operational cost.
11. Refinement of human behaviour towards intended objective or goal viz. safety outlook, interest and safety mindedness, production and quality orientation etc.

The benefits of value measurement of safety training programme are:

1. The top management understands usefulness and cost effectiveness (in relation to accident costs) of the training programme.
2. Confidence, morale, skill, status, prestige etc. of the employees and the company itself are seen improved.
3. Most effective loss prevention measures can be segregated for repetition.
4. Strengths and weakness are highlighted and suggest the steps for next programme.
5. Safety professional can find out and promote most effective programmes.
6. It can be determined whether objectives/goals are met and reason of gap if any. This is useful in reviewing the programme.

For evaluation participant and/or supervisors reaction should be assessed through interviews or questionnaires. Following questions are useful in such assessment.

1. How much change occurred ?
   The criteria include knowledge, attitudes, skills, behavioural change on the job and/or improvements or decrements in organisational results. These criteria can be measured by paper and pencil tests, questionnaires, work sample tests, timings of performance etc.
2. Can the change attributed to the training programme ?
3. Was the training worth the effort ? Here cost of training is justified against gain to the organisation.
4. Whether employee development needs are fulfilled ?

This can be judged through effectiveness, efficiency and affirmative action and helps to guide decisions concerning planning, programming and budgeting.

Assessment is carried out by using Rating Form (see Table-5, Chapter-32) where activity standards and rating norms (poor, fair, good, excellent) are prescribed and marks are given. Activity standards can be decided for (1) Organisation & Administration (2) Industrial hazard control (3) Fire control (4) Health and Hygiene (5) Participation, motivation and training (6) Accident investigation, statistics & reporting procedure etc.

After evaluation, its results should be utilised to review the programme. Such review will give (1) Agreed recommendations for future action (2) An agreed action plan for the department (3) A follow-up and action plan for agreed recommendation.

After review a new (improved) safety (training) programme will take shape with drawbacks filtered and more effectiveness and usefulness reinforced. This process of refinement of better and better training programme yields good results.

11. EMPLOYEE PARTICIPATION IN SAFETY

11.1 Purpose :

Employees are the major work force working under hazards. Some know the hazards and some do not It is of great importance that they must realise that they would be the first victim of any accident, their safety awareness and all accident prevention work is in their interest and therefore their active participation in showing hazards and helping in removing them by the joint efforts of management and all employees is most desirable.

Section 41G of the Factories Act speaks worker's participation in safety management. A method of safety committee is suggested. Right of workers to warn about imminent danger is also created by sections 41 H 111A of the Act. Display of the Extract of the Act and Rules (Section 108(1), Rule 106 and Form No. 23) is for the same purpose of making workers aware and to call for their participation. Some areas and methods of participation are discussed below:

11.2 Areas of Participation :

General areas of participation are as under :

1. To set safety goals and training programmes.
2. To design and improve standard operating procedures (SOPs) and methods of operation.
3. Appraisal of progress towards goals.
4. To give, collect and discuss safety suggestions and to implement which are necessary. Rewards for good suggestions boost up motivation for participation. '

McGregor's theory states that **participation management** has a basic belief in the competence and abilities of individual employees regardless their status in organisation. Employees' and supervisory participation is essential for success of any safety programme.

When workers are taken into confidence in designing any .safety programme or goal they feel themselves responsible for its success. This element of involvement and joint responsibility is most fundamental to employee participation.

Statutory areas are discussed in Part 11.3.1 below.

11.3 Methods of Participation :

11.3.1 Safety Committee :

Rensis Likert has described four types of management systems within an organisation (1) Exploitative authoritative (2) Benevolent authoritative) Consultative and (4) Participative. This last approach of participative concept is adopted by many countries and joint efforts of workers have resulted in reducing accidents.

Statutory Provisions:

A new provision was added since 23.09.87, u/s 41 G of the Factories Act to set up a safety committee consisting of equal number of representatives of workers and management to promote co-operation between the workers and the management in maintaining proper safety and health at work and to review periodically the measures taken in that behalf.

Thereafter by addition of rules 68F&Y in the Gujarat Factories Rules, on 15-2-1995, following revisions are added regarding safety committee :

Applicability:

1. Factories employing workers more than 250.
2. Factories carrying dangerous operations u/s 87.
3. Factories listed in the First Schedule.

Formation, Tenure & Rights:

1. A senior official shall be the Chairman.
2. A Safety Officer or Factory Medical Officer shall be the Secretary.
3. A representative each from the production, maintenance and purchase departments shall be members.
4. Workers representatives, of equal number, shall be elected by the workers.
5. The tenure of the committee shall be 2 years.
6. At least one meeting in 3 months. Minutes shall be recorded and produced before the Factory Inspector on demand.
7. The committee has right to be informed of potential hazards of work places and data on accidents and working environment. The committee shall keep the data confidential and use it solely to guide on safety measures.

Functions & duties:

1. Co-operation to implement health and safety policy.
2. All matters of health, safety and environment and solutions to problems in that regard.
3. Creation of safety awareness amongst workers.
4. To conduct educational, training and promotional activities.
5. To discuss reports on safety, health and environmental surveys, safety audits, risk assessment, emergency plans and implementation of the recommendations of the reports.
6. To carry out health and safety surveys and identify causes of accidents.
7. To look into complaints of imminent danger and suggest corrective measures.
8. To review the implementation of its own recommendations.
9. To form sub-committees, if necessary.

The main object of the committee is to advise to Managing Director and the Safety Board or the top executive of the company on all matters of safety and health of the workers. It is not a substitute for the management. Like other committees it is an organ or part of the management function and helps the management in specific area of safety. It is a body of safety representatives for group suggestions and decisions, co-operative safety efforts and a two-way channel of communication through which suggestions can flow from employees to management and vice versa. It does not bypass the overall management control of general supervision and communication, but it aids to it.

Its advantages are: It (1) brings together varying view points, yield sounder .decisions than the individual members (2) widens interest by allowing participants of work-people in their own .work and (3) allows checks and cross-checks by different opinions which are essential for safety.

Its disadvantages are: It (1) causes delay in 2. decisions till the meetings are held (2) consumes more time in meetings' (3) may sometimes turn into a trade union meeting if so pulled by the employees. Therefore its good control to the point is necessary.

Types of Committees may be: (1) Main or Central Safety Committee (2) Plant or Shop Safety Committee (3) Technical Safety Committee (4) Special purpose Safety Committee etc.

Technical Safety Committee is useful for specialised knowledge viz. guard design, process and engineering revision, hazard and risk analysis, special investigation etc. It comprises of chief engineer, safety engineer/officer, head mechanic, chief chemist and similar expert technicians.

Special Purpose Safety Committee can be setup for specific jobs and dissolved when its purpose is accomplished. Such jobs include special accident investigation, specific problems of worker behaviour, off-the job safety, rehabilitation or relief problem, safety celebration or contest or award occasions etc.

For a big concern different safety committees as ' stated above are possible, but in a small factory a single committee can carry out all functions.

Size of Committee depends on size of establishment, quantum of unsafe conditions/acts, size and relationship of various departments/units, type of business etc. Workers' representatives should not be less than that of the management.

Its Essential Requirements are: (1) Set-up should be appropriate to the work (Main Committee to include 12 key executives) (2) Members should be well-known and have respect to fellow-members (3) Members must be well aware of working conditions, work methods, practices, hazards, causes of accidents and remedial measures, and (4) It should be as small as possible with minimum members from the sections necessary.

Policy and Procedure: When a committee is formed, written instruction should be issued covering (1) Scope of activities (2) Extent of authorities and (3) Procedure as to time/place of meeting, frequency of meeting, order of business, records to be kept and attendance requirements. The management should make it clear that it wants results and should give effective executive supervision over the affairs of the committee. The committee members should have firm determination to advance the cause of Safety.

Some non-statutory functions are as under:

Functions of Main/ Central Safety Committee arc:

1. To decide safety policy and planning for purchase of equipment with in-built safety devices, relationship between departments standards to be followed in guarding, testing designing, layout, housekeeping, material handling and placing, inspections, accident investigation and records etc.
2. To plan and supervise programmes of safety propaganda, education, training and maintaining interest of employees in safety.
3. To make arrangement or develop safe work practices and procedures; inspection, audit and appraisal systems and all efforts to avoid or reduce accidents. To discuss and control the accident rates.
4. To discuss and initiate action for correction of unsafe conditions and actions. Action plan should be drawn and suitable dates fixed for completion of each task.
5. To suggest safety devices and protective equipment.
6. To carry out fire drill and rehearsal of on-site emergency plan.
7. To scrutinise safety suggestions received through plant safety committees and to initiate action to implement the accepted suggestions.
8. To arrange safety competitions and to decide awards for encouragement.
9. To improve co-operative spirit between management and employees and among various departments to promote safety .

10. The safety knowledge of committee members should be increased by arranging lectures of safety experts of the plant and outside and by sending the members to seminars. Factories inspectors and safety specialists can be utilised for this purpose.
11. To discuss and approve safety budget.
12. To discuss, distribute and supervise responsibilities for quick compliance of safety remarks.
13. To suggests changes in safety organisation and its activities for better performance.
14. To suggests safety aspects of new design and construction of plant, machinery and equipment and
15. To decide disciplinary procedures and disposal of specific safety problems.

Functions of Plant Safety Committees are:

1. To review accident records.
2. To investigate accidents and to implement corrective actions.
3. To implement directives of the Central Safety Committee.
4. Enforcement of safety rules, procedures an accepted safe practices.
5. To encourage and enforce the use of persona protective equipment.
6. Safety inspection rounds of various shops an< sections.
7. To encourage safety suggestions from worker and to forward them to the Central Safety Committee.

11.3.2 Workers' and Union's Participation :

Equal number of safety representatives from workers (or their union) and management should constitute their joint safety committee. This may be a central one or different in different plants. All must be sincere in their desire to co-operate in the matters of safety. Scope of the activities and agreement should be limited to Safety. Union representatives should be selected from the basis of their safety knowledge, interest and experience and should be cooperative and sincere. They should not bring other union demands like bargaining, grievance setting etc. in the meeting of safety committee. Union must recognise management's right of leadership in a joint safety programme. Accident prevention is an area of mutual interest and not of dispute or quarrel. Therefore the workers or union must participate to show their abilities in this area and thus strengthening their relationship with the management and saving their own lives from accidents.

Central Board for Workers' Education, Ministry 'of Labour, Govt. of India runs many schemes for workers' education and training such as (1) Tripartite scheme (2) A worker to worker training scheme (3) Voluntary scheme (4) Need based education (5) Education Officer's training programme (6) Worker Teacher’s training programme (7) Workers' training programme etc. In Gujarat the first workers' education I centre was established in 1967 with the co-operation of the State Govt, employers and trade unions.

The Central Labour Institute at Bombay, Gandhi V- Labour Institute at Ahmedabad and some trade unions also run such education and training classes for workers. All such efforts should increase workers' participation in safety.

See Part 6.7 also.

11.3.3 Supervisor's Safety Contact :

In foregoing Part 6.5 of this Chapter, role of the supervisors is explained at length. By their key position between workers and management and by their constant contact with workers they can easily and effectively promote workers' participation in safety. The supervisor should always try to get such participation. A critical incident technique explained in Part 1.11 and -1.12 of Chapter-19 is based on such safety contacts of plant people. Safety contact by safety manager, safety engineer/officer is also useful.

11.3.4 Safety Suggestion Scheme :

This is an old practice to invite safety suggestion for improvement in process, method, equipment, safety meetings, contests, inspection procedure etc. Criticisms should be replied in the plant magazine or on the notice board to provoke further suggestions and ideas. For suggestion scheme to be successful it is advisable that the employees' effort must be acknowledged, even if the suggestion is not adopted. It must be given careful consideration. Good suggestions should be rewarded among others to encourage them to participate. Written suggestions are the best, but, the oral or telephonic should also be allowed. Sometimes a contest of submitting good suggestions provides useful information and stimulates such effort. This system is effectively accepted by Japanese management. Boxes and forms can also be used to collect suggestions.

11.3.5 Safety Competitions:

This is another method of workers' participation in safety. Competitions (contests) are of two types: (1) Individual comparison - where individual worker takes part in competition and award is given by comparing individual performance. Examples are safety speech or quiz, essay, poem or slogan writing, posters or cartoons etc. (2) Group comparison - where groups take part in competition and award is given by comparing group versus group. Examples are department wise housekeeping competition.

11.3.6 Safety Incentive Schemes :

(i) Financial Incentive:

Financial reward to the most useful suggestion or activity in safety is the commonest method. Other financial incentives should also be given for suggestion to solve particular safety problem of plant or process, machine or equipment etc. Suggestion of good design for a guard or safety device should always be rewarded by handsome amount.

(ii) Non-Financial Incentives:

Award for safety performance, trophy, memento, certificate of merit, public honour, praise or pride, awarding special safety hat or kit or symbol of recognition, awarding special status and duties of safety work, giving special position such as honorary member of safety committee, raising the cadre or post, giving extra designation for any remarkable safety contribution are all examples of non-financial incentives.

These non-financial incentives are self preservation, personal and material gain, loyalty, responsibility, pride, conformity, rivalry, leadership, logic and humanity. If these incentives are properly utilised they help much in accident prevention work.

Safety performance (frequency and severity rates) of different groups can be compared for the same period. Here groups are motivated for competition. Similarly factories can be invited for contest if district, state or nation-wide competition is arranged. State and National Safety Councils do this. Every year safety competitions are held among similar class of factories to boost up safety activities and group motivation.

In any type of safety contest the rules of contest and comparison must be well defined, declared beforehand and fair and reasonable to all participants. Scoring system should be simple or easy to understand. Winners may get shield, certificate or good prize but non-winning participants should also be compensated for encouragement. The competition movement as a whole should be encouraged as this effort itself is most important. Care should be taken to avoid any discredit. Cheating or malpractice like compelling an injured worker to continue work to show less man-days lost, shall be disregarded. Similarly false reporting of safety figures should also be avoided. Competition should be fair and fine and fitting to its noble cause.

Safety Quiz is one type of safety competition or contest. It can be conducted by asking questions to participants or by giving them an objective question paper containing quiz questions to be answered in a stipulated time. It touches wide area of safety in short time and participation looks live.

11.3.7 Audio-Visual Publicity :

As we saw in foregoing Part 10.7 of this Chapter, a trainee tends to remember 50% of what he sees and hears and 70% of what he sees and talks. This is possible by audio visual aid only. Television and video effectively reproduce actual happening. Therefore safety education and training by safety films on TV is the most powerful method. Only difficulty is in getting safely films or safety video cassette easily and frequently. This should be made possible if we wish to utilise its full role in increasing safety.

Slides, filmstrips and transparencies are easily available or prepared and therefore they should be used to die extent possible to hold the picture to discuss and understand it in details which is not possible with a moving film.

Modern media is a closed circuit television. Travelling units are complete television studios in themselves and have up-to-date equipment with the control room housed in a single vehicle. There are fixed and moving cameras, telecine equipment, a video tap recorder and monitor screens which can be installed up to 500 meter away from the studio. Using both inside and outside cameras, extensive safety programmes can be broadcast through the closed network. Such unit can be hired also.

11.3.8 Other Promotional Methods :

Other promotional teaching methods for employees' participation are safety posters, cartoons, signs and slogans, publications, booklets, bulletin boards, safety contests and rewards, counselling of education and training, demonstration, safety meetings, safety campaigns and stunts, first-aid training, fire brigades, safety- inventory or questionnaire, accident investigation, inspection, job safety analysis etc.

12 APPROACHES TO COMPLIANCE & VIOLATIONS:

12.1 Approaches to Compliance

All rules are for compliance. Rules on paper are no rules. Rules in effect are real rules. Strict and quick compliance of safety rules is most desirable. Poor or no compliance goes against safety. No compliance of statutory provisions may bring dire consequences. Loss of various types results in decreasing productivity. Therefore measures for compliance of safety rules must be adopted whole-heartedly.

Responsibility for compliance should be fixed and so divided that the compliance is achieved and reported within stipulated time. Action for compliance should be started at once and interim reply should be given if the action is still continued. Probable time for completion should also be reported.

Defending delay or avoiding compliance is of no, use. Effective measures for speedy compliance should be determined and applied. Preventive and corrective maintenance, trained team, sufficient spares and tools, ready procedure, drawing, charts, tables, extra equipment and safety devices are good measures for' quick compliance.

The measures may vary according to the matters to be compiled. Quick decision for selection of measures for compliance is equally important.

When some rules are not, compiled their reasons must be considered. The reason may be fault with rules, employees or supervisors. Such fault should be detected, studied and removed to achieve compliance.

12.2 Approaches to Violations:

Violation of safety rules must first be detected and removed. Violation may result in accident and economic losses. It must be prevented. Rules are made for non-violation. Therefore no violation should take place.

However if it takes place, it should be studied and its reason should be removed. Violation of statutory rules may result in prosecution and compensation. Despite of this legal proceeding it adversely affects health and safety of work people.

Violation of non-statutory internal rules calls for disciplinary action. If such corrective action is not taken, the rule ceases to exist. First correction is to teach the requisite measure for compliance so that the mistake is realised and action is soon taken for non-recurrence.

If repeated violation is noticed, some appropriate punishment may be necessary. Only punishment will not serve the purpose, as solution of unsafe behaviour is not any admonition or penalty. Anyhow requisite safe behaviour must be reflected and that is the real solution.

Normally the approach to violation of a safety rule should be to detect and remove the cause and not to find and punish a wrong doer.

E X E R C I S E

1. Comment on following explaining it is True or False:

1. The oldest views on 'management' found in ancient India are well explained.
2. Elements and principles of management are the same.
3. Safety management in industry is evitable.
4. Leadership is not essential in safety management.
5. Trade union's role in safety management should be co-operative with the management.
6. MGO can function better than the Government organization in the field of safety.
7. Training for safety is a waste of money.
8. Methods and types of training are the same.
9. Workers are reluctant to participate in a safely programme.
10. Approach to violation of safety rules is to find and punish a wrong-doer.
11. Supervisors should not be blamed for accidents.
12. Human Resource (personnel) aspect is equally important as the material resource aspect in safety management.
13. Supervisor is a key person in any safety programme.
14. Management should take leadership in safety.
15. Safely committees are usually not effective.
16. Safety is the line responsibility and staff functions.

17. Management's 'involvement' is more important than its 'support' in safety.
18. Trade unions have to play a vital role in the interest of safely.
19. Supervisor is a link between management and the workers.
20. Management is more responsible than workers for safety.

2. Write Short Notes on:

1. Old Indian concept of Management.
2. Old foreign concept of Management.
3. Definition of 'Safety management.
4. Nature of management.
5. Seven elements of management.
6. Types of management.
7. Span of management.
8. Planning for safety.
9. Definition and areas of 'Safety planning'.
10. 'Planning premises' for safety.
11. MBO OR MBE.
12. General definition and types of organization.
13. Definition and need of safety organization.
14. Techniques of direction.
15. Leadership styles.
16. Process of communication.
17. Barriers of communication.
18. Group dynamics OR Two-way communications.
19. Safety policy OR Purchasing policy.
20. Role of safety organizations in Gujarat OR Elements of a training cycle.
21. Duties of a Safety Officer.
22. Attitudes of a Safety Officer.
23. Objectives of Safety training.
24. Modern methods of training safety training.
25. Kinds of supervisory problems.
26. Benefits of training programme.
27. Safety committee.
28. Reasons of failure of safety committee.
29. Steps to revive the usefulness of safety committee.
30. Safety suggestion scheme.
31. Safety competition or contest.
32. Psychological safety rules.

3. Explain, State, Narrate or Describe in detail:

1. Evaluation of Management thoughts OR Thoughts of scientific management.
2. General definitions (any three) of management
3. Elements of management functions.
4. General principles of management.
5. Strategic planning.
6. Role of MBO in safety.
7. Role and functions of a leader OR Attributes of a leader.
8. Definition and purpose of communication.
9. Essential of effective communication.
10. Definition and steps of controlling.
11. Statutory duties of Safety Management.
12. Role of Supervisors in safety.

13. Role of Workers in safety.
14. Role of Trade union in safety.
15. Role of Competent persons in safety.
16. Role of Safety specialists or Professionals.
17. Role of the Government in safety.
18. Size, Status and Functions of Safety department
19. What do you mean by a Safely programme? What could be the areas of such programme?
20. The steps of training process.
21. How will you assess the training needs? OR How will you integrate safety training with job training?
22. Methods of training OR Types of training.
23. You are a Safety Officer. You have to plan a training programme for new workers. State in brief what topics you will include.
24. Narrate the content of a training programme for safety supervisors.
25. What are the indicators of a successful training programme?
26. State areas of participation by workers OR their duties and functions.
27. State various methods of participation in safety activity of a factory.
28. Explain the functions of a safety committee.
29. Explain the needs for safety rules, procedures, codes etc.
30. What should be the criteria to formulate safety rules?

4. State the Difference between:

1. Authority and Responsibility
2. Authority and Power
3. Tall and Flat structure of management.
4. Delegation and Authority
5. Delegation and decentralisation of Authority.
6. Directing and Co-ordinating.
7. General planning and Strategic planning.
8. Formal and Informal communication.
9. Oral and Written communication.
10. Role of a Competent person and that of a Safety Professional (specialist).
11. Safety education and training.
12. On the job and off the job training.
13. Individual v/s mass training.
14. Safety policy and safety committee.
15. Financial and non-financial incentives for safety.
16. Statutory and non-statutory safety rules.

CHAPTER – 7

Plant Siting and Safe Design

THEME

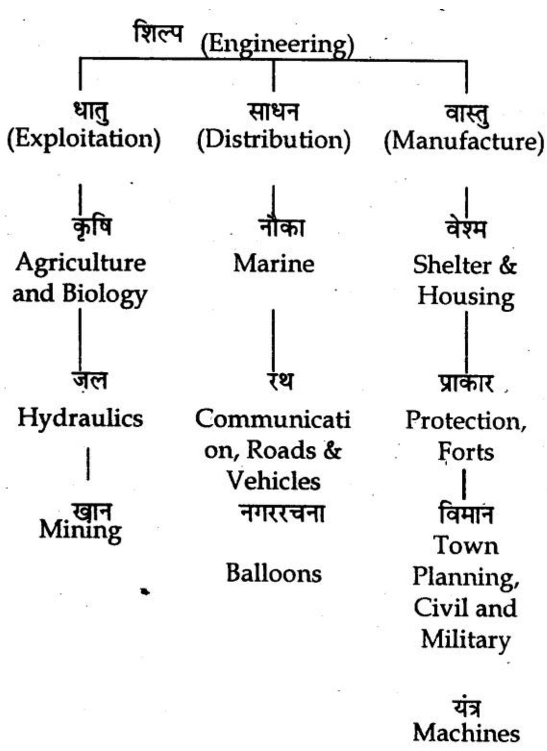
1 INDIAN HERITAGE

When we look at the old Indian structures and architectures which still exist, really we surprise. Without the aid of modern engineering drawing, techniques, lifting and shifting machines, our forefathers had designed and constructed such an amazing architecture which was unparallel not only in that time but also in present era.

Various temples, forts, step-wells; etc., on mountains and in towns, Tajmahal and leaning towers, varieties of monuments and antiquities, sculptures, incarnation, places and havelies of aesthetic and historical value are some of the glorying examples of our cultural heritage and archaeological wealth. List of sites and details can be had from the Department of Archaeology. We were ahead in the world in safe design, layout and construction of structures of those days. A remark of Claude Batley, A.R.I.B.A. F.I.I.A. describes as under:

"The great heritage of Indian architecture has been neglected and many modern buildings are exotics unfit to exist in India's climates, under its often vertical sunlight and its monsoon winds and rains. The essential of Indian traditional architecture are : The stone plinth, the thick walls, the window openings extending to the floor so that the air may circulate freely, the internal courtyard, the caves, the terraced roof. **Above all, planning was employed to increase the health and amenities of the community."**

According to Hk`xq f'kYi lafgrk (Some 1000 years BC), 'kqØuhfr v/;k; & 4 and page 20, izkphu fgUnh f'kYi'kkL= Hkkx &1] iquk 1928] Bharatiya Schools of Engineering are as under:



There were 75 sub-branches of above main branches of engineering.

As published by Rao Sahib K.V. Vaze, LCE, Bombay, PWD, in Vedic Magazine, Lahore, January 1924 main ten branches of Bharatiya Engineering were as follows :

1. d`f"k'kkL= Propagation, agriculture, biology etc.
2. ty'kkL= Imsrrm Hydraulics.
3. [kfut'kkL= Mines and minerals, stones, metals etc.
4. ukSdk'kkL= Navigation, boats, playing in rivers, tank, sea etc.
5. jFkk'kkL= Construction of roads, vehicles, carts etc.
6. vfXu;ku'kkL= Aeronautics.
7. okLrq'kkL= Building construction, houses etc.
8. izkdkj'kkL= Defensive workes, fort, trenches, protection etc.
9. uxjpuk'kkL= Town planning.
10. ;a='kkL= Machines, Mechanics etc.

Qualities of an engineer (LFkifr) are described in e;er v/;k; & 5 izkphu fgUnh f'kYi'kkL=] Hkkx&1 as under.

LFkifr% LFkkiukgZ%L;kr~ loZ'kkL=fo'kkjn% A
u ghukaxksfrfjDrkaxks /kkfeZd'p n;kij% AA

vekRl;ksulw;'p rkaf=dLRofHktkroku~ A
xf.krK% iqjk.kK% lR;oknh ftrsafn+;% AA

fp=Kks ns'kdkyK'pkUun'pkI;yqC/kd % A
vjksxh pkizeknh p llrO;luoftZr% AA

An Engineer should be fully qualified and capable of doing all types of construction work. None of his body parts should lie defective or excessively short or long. He should be practitioner of Dharm, benevolent, unmistaken, active, mechanic, healthy, tolerant toward others' progress, mathematician, historian, truthfully and self controlling. He should be well conversant with drawing, design, time, weather and meteorology. He should be free from disease, laziness and seven evils of greediness, intoxication, gambling etc.

A book Indian Sciences and Scientists' by N.K. Jain, Delhi, throws much light on our ancient advancement in many faculties of science, engineering, medicine, surgery etc. Nalanda and Takshshila were the world famous universities where even foreign students were also learning. Hu-en-Chang of China was one of them.

Now let us see the current provisions for constructing a factory.

2 STATUTORY REQUIREMENTS UNDER. THE FACTORIES ACT & THE G JARAT FACTORIES RULES :

Following arc some useful points for design, layout and construction of a factory and preparing plans for the purposes of the Factories Act and Rules. The plans are to be submitted to the concerned Factory Inspection Office. Plans are required u/s 6 of the Factories Act 1948 and. u/r 3 & 3B of the Gujarat Factories Rules 1963. Following details must be considered at the initial (design) stage of preparing plans.

In following parts, 'sec' means section of the Factories Act 1948 and 'rule' means rule of the Gujarat Factories Rules 1963.

2.1 Points at Drawing (Blue-print) Stage :

Rule 3B states that plans of the factory drawings should be drawn to scale and should include factory site, surrounding buildings, roads, drainage etc., plan, elevation and cross sections of the buildings showing lighting, ventilation, means of escape, plant and machinery layout, aisles, passage ways etc.

Rule 3C requires drawings for every work of engineering construction i.e. any building, tank, silo, scaffold, platform, chimney, bridge, supporting structure, retaining wall or any similar structure.

After approval of such drawings, a Stability Certificate in Form No. IA is to be obtained from a Competent Person recognised u/r 2A by the Chief Inspector of Factories and should be submitted to the Factory Inspection Office. Fresh certificate is required after each period of 5 years or after every extension, alteration, repairs, or addition of machinery, plants etc. Manufacturing process cannot be started if such certificate is not obtained and sent to the CIF.

Only applicable requirements should be furnished. All attachments should be in duplicate, signed and stamped by the Occupier of the factory and in order. All drawings should have been to proper scale and with north direction shown. Proposed construction / alteration / arrangements should be shown in red and that to be removed in yellow. Factory boundary should be shown in green including all its premises and precincts therein.

All figures, dimensions, specifications, distances and necessary schedules of doors, windows, machinery and equipment should be shown on plans at proper places. The requirements are as follows :

1. Plans in ammonia(blue) or modern prints (white with black lines) showing details of site ' (location), all buildings and machinery layout including lifting machines,- pressure plants, storage & process vessels, godowns, warehouses, stores, furnaces, means of access, stairs, floor openings, pits, reservoirs, sumps, tanks, boiler house, coal yard, generator room, effluent treatment plant, mess room, water facilities, etc., workshops, canteen, rest-lunch room, creche, cloak-room, first-aid or ambulance room, drinking water centres, latrines, urinals, washing places, spittoons, fire protections, emergency control room, locations of FEE & PEE, tools & transport equipment, means to remove heat, dust, fume, vapour, smoke, gases, airborne contaminants, radioactive waste etc., adequate lighting, ventilation, temperature and noise control; necessary elevations, end-views, cross-sections showing roof design and other details and all safety measures to be provided.

2. Certificate from local authority viz. Gram Panchayat, Nagar Palika, Municipality, I Corporation, Industrial Estate, Urban Development Authority, Collector etc. regarding permission for the site of the factory.

3. Form No. I, GFR, duly filled in with necessary enclosures.

4. Annexure-7 u/r 68J, GFR, and u/r 7(1), MSIHC Rules, in case of a hazardous factory.

5. Annexures 8 to 10 u/r 10(1), 17 and 18(5) of the MSIHC Rules, 1989, in case of hazardous chemicals or/and MAH factory.

6. Stability certificate from a Competent Person in Form IA to be submitted before starting a factory.

7. List of raw materials with their storage quantities and parameters.

8. List of products (including by-products) with their production capacities.

9. Process flow chart and description of manufacturing process in brief.

10. List of machinery with their Horse Powers and other capacities.

11. MSDS and safety manual in case of chemical factories, and information required by the Site Appraisal Committee u/s 41A, if such Committee exists.

12. Details of safety fittings, equipment, tools, devices and measures to be adopted with the list of protective wears and fire protection to be provided.

13. Details of fire water reservoir, pumps, suction, hydrants, fixed fire installations, control valves etc.

14. Copy of the last site plan and plan-approval letter from the Chief Inspector of Factories, in Case of plans for extension / alteration of the factory.

15. Copy of approval from or application to the State Pollution Control Board in case of factories polluting land/water/air.

16. Copy of approval from or application to the Explosive Dept. in case of factories using/ manufacturing explosive substances.

17. Copy of approval from or application to the Prohibition Dept. in case of factories using/ manufacturing prohibited substances.

18. Load-bearing calculations for the stability m the structure.

19. Any other information required by the Factory Inspection Office.

20. A forwarding (covering) letter mentioning which items from the above (1) to (18) is submitted therewith.

Minimum Dimentions :

(A) Roof Heights (minimum required):

For RCC Slab/Tiles/False Ceiling	-	12’ or 3.7 M
AC Sheet	-	16’ or 4.9 M
GI Sheet	-	18’ or 5.5 M

To prevent fall accidents, it is highly essential to use unbreakable metal sheet instead of a fragile AC sheet as roofing. Now a days, reinforced plastic sheets are available against the normal fragile AC sheets. Fragile AC sheets are unsafe as they have caused many fatal (fall) accidents.

Minimum roof height for Canteen, Shelter, Rest room. Lunch room and Creche - 12' or 3.7 M. (B)

(B) Other Dimensions (minimum required):

1. Work Room area (Sq.M) $\geq$

$$\frac{\text{(No. of Workers in the room x 14.2) + Volume in cub m. of machineries in the room}}{\text{Height of roof in m. (Consider max. 4.2 m only)}}$$

2. Sanitary Blocks (Sec. 19 & 42)

Latrines	-	16 SF or 1.5 SM
Urinals	-	12 SF or 1.1SM
Bathrooms	-	24 SF or 2.2 SM
No. of Latrines	-	As per Rule 41, GFR
For Females	-	1 per 25 females
For males	-	1 per 25 up to 100
	-	1 per 50 thereafter.
No. of Urinals	-	As per Rule 45
For males	-	1 per 50 up to 500
	-	1 per 100 thereafter.

No. of Bathrooms/Washing Places - As per Rule 68W, 69 and 102, GFR.

No. of Taps - 1 per 15 workers or as per Schedule in the Rule. At least 27.3 litres water per worker per day is necessary.

Note : Latrines and urinals should not open in work-room. Bath-rooms should not be in the vicinity of latrines and urinals. There should be separate latrines and bathrooms for males and females maintaining privacy and sign boards. Requirements of Sec. 19 and Rule 41 to 50 should be fulfilled.

3. **Ventilating Openings** in a workroom (Rule 18A): = 15% of the floor area (min).

4. **Quantity of fresh air** by mechanical means (Rule 18A): == 6 x workroom volume (M^3) per hour

5. **Thermometer height** (Rule 18A) : = 1.5 m- from the floor.

6. **Spittoon Stand** (bracket) height (Rule 51) = 0.914 m. or 3 ft from the floor.

7. **Cloak-rooms :** Necessary for the factories in Schedule u/r 69-A and 102. It is advisable to have separate cloak rooms for males and females.

8. Ambulance room : (Applicable for workers 500 or more) As per Sec 45 and Rule 71.

   Minimum Area necessary - 250 SF or 24 SM

   It should contain items mentioned in Rule 71(3).

9. **Canteen** (applicable for workers 250 or more) As per Sec 46 and Rule 72 & 73.

   Minimum height - 12 ft. or 3.7 mt.
   Minimum Area for dining hall = 1 SM or 11 SF per worker of 30% of workers working at a time. (Area occupied by service counter and furniture except tables and chairs should be excluded).
   Canteen should be at least 50 ft or 15.2 m. away from latrine, urinal, boiler house, coal stacks, ash dumps etc.

10. **Shelter, Rest rooms & Lunch rooms** (Applicable for workers 150 or more) Sec 47 and Rule 79. Minimum Area = 1 SM or 11 SF per worker.

11. **Creche** (Applicable for 30 female workers or more) As per Sec 48 and Rule 80 & 81 Minimum area = 2 SM or 22 SF per child.

12. **Special provisions u/r 102, Schedules for Dangerous Operations :**
    1. Air space per worker in a room > 14.2 m^3 or 500 ft^3 where height over 3.7 m. or 12 ft shall not be accounted.
    2. Pasting distance and rack/shelf size - as per Sch. 3
    3. Washing facilities : Spacing 61 to 120 cm between two workers or water pipes, .Pipe height = 2.1 m, dia == 2.5 cm.
    4. Mess room size = 0.9 m^2 per worker, height 3.7 m or more
    5. Vessel fencing : Height 91.4 cm. or 3 ft
    6. Plank or gang-way width = 45.7 cm.
    7. Toxic or flammable solvents : Two exits in each room. Two means of escape from the building. Doors should open outward.

13. **Cotton Textile, Ginning, Wood-working and Rubber Mills, Centrifugal m/c. Power press, Shears, Slitters and Guillotine m/c.** As per Rule 54.

14. **Hoists / Lifts / Lifting Machines**. As per Sec 28, 29 and Rules 59, 60 & 60A.

15. **Pressure Plants.**
As per Sec 31 and Rule 61.

16. **Floors, Stairs and Means of Access.**
As per Sec 32, 38 and Rule 66, 67.
Minimum width of fire exit 3' or 0.91 m. and minimum height 6.6' or 2m. as per Rule 66(l)(b). One or two separate stairs necessary as per Rule 66 (l)(c) or (d). All means of access should be shown clearly.

17. **Minimum Dimensions of Manholes :** As per Rule 64.
Size : 0.41 m x 0.31 m or 1.35' x 1.0' or 0.41 m or 1.35' diameter.

18. **Machine Distances ;** Normally a distance of 3' or 1m should be kepi between a machine and the nearest machine or a fixed structure (e.g. wall).

19. **Dimensions of Fire Exits (Rule 66A)**
An exit includes doorway, corridor and passageway but does not include lifts, escalators and revolving doors. The exit should provide continuous (unobstructed) and safe egress (departure) by fire resisting wall. See item 9 (24 points) in Part 3.1 of Chapter-13 for fire exits specifications.

20. **Storage of Material (Rule 66A) :**

    1. Passage width between two piles > 90 cm.
    2. Clearance between ceiling and the pile top > 2 m.
    3. Safe distance in heaps of flammable material. Open ground storage at minimum distance of 10m from process or storage building.
    4. Gas cylinders should be away from highly flammable substances, furnaces and hot processes. Roof and adequate ventilation are necessary.

21. **Location of Fire Extinguishers (Rule 66A):**
750 mm above the floor level.

22. **Explosion Panels (Rule 68G) :**
Size 2200 cm2 per I m-" volume of the oven/drier.

23. **Ship ladders or sound Gangways (Rule 68H):** Width > 55 cm, each side railing 90 cm. ht.

24. **Wash tank of clean water in electrolytic Plating Works (Rule 102, Sch. 2)** :
Size 1500 Litres.
Washing space between two workers 1.2 m.

25. **Solvent Extraction Plant (Rule 102, Sch. 21)**
    1. Plant 30 m away from the nearest locality.
    2. 1.5m high fencing at a distance of 15 m from the plant.
    3. Boiler House etc., at a distance of 30 m or more from the plant.
    4. If any construction or process is within 30 m from the plant, barrier wall of noncombustible material and 1.5 m high at a distance of 15 m from the plant.
    5. No solvent 'shall be stored in plant building. Space of 15 m within the plant shall be kept free from combustible material.

26. **Pottery Works (Rule 102 Sch 25) :**
    1. Mess room size 0.93 m2 (minimum)

2. Water stand spacing 1.2 m. (minimum)

27. **Foundry Works (Rule 102, Sch 26) :**

1. Gangway width
   If not used to carry molten metal - 0.92 m.
   If used to carry molten metal -0.6m to 1.8m as prescribed.
2. Pouring aisle width - 0.46 m to 0.76 m as prescribed.
3. Safety distance - 4 m from the delivery spout, or 2.4 m from ladle.
4. Wash stand spacing - 1.2 m.

Note : Details of I to 27 above should be shown in the plans. It will highlight the points of legally safe design.

2.2 Cleanliness and Good Housekeeping :

Sec. II, 20 and Rules 16 to 17 A and 51 to 53 deal with this subject. Where a floor is liable to become wet due to manufacturing process, effective means of drainage should be provided.

Effective means of keeping the factory (including compound) clean by washing, sweeping, brushing, dust or vacuum cleaning should be provided. White washing, colour washing, varnishing, painting etc., should be carried out as in Sec II (l)(d) except in factories exempted u/r 16.

Spittoons should be provided in convenient places on a stand/bracket 3' or 0.91 m high in a clean and hygienic condition.

Good housekeeping is a wider term than cleanliness. It includes in its sphere orderly plant and machinery layout, storage, interior arrangements, equipment, floors, drains, pits and manholes, stairs and platforms, sanitation and ventilation, colour, illumination and electric fittings, fire extinguishing system, yard areas and compound, safety and first-aid, display of notices and instructions, and identification and removal of hazards. Good housekeeping helps in increasing productivity and in decreasing accidents and fatigue in workers. .

For details see Chapter-8.

2.3 Disposal of Effluent and Air Emissions ;

Sec. 12 & Rule 18 deal with this subject.

To connect drainage system of a factory with public sewerage system, permission of local authorit and for other mode of disposal, permission from Health Officer is required.

Three Central Acts (1) Water (Prevention & Control of Pollution) Act 1974 (2) Air (Prevention e Control of Pollution) Act 1981 and (3) Environment (Protection) Act, 1986 are administered by Central and State Pollution Control Boards. Therefore, their approval/consent is also necessary for disposal of effluent and air emissions. For details see Part 10.1 to 10.15 of Chaoter-28

Various Indian Standards are prescribed for tolerance limits of many characteristics of effluents and sewage to be disposed. For details see Part 10.6 of Chapter-28 and Tables II to 14 of Chapter-32.

Pre-treatment, storage or equalisation tank, primary treatment, secondary or biological treatment and tertiary treatment are the treatment methods generally employed in sequence. An incinerator is used to burn the solid or liquid waste. After testing the effluent sample, appropriate method should be selected. See Table 16 of Chapter-32.

Method for disposal of contaminated air/gas should also be selected. Description of method for effluent disposal and tolerance limits to be achieved after treatment should be submitted along with the plans.

For details see Chapter-18.

2.4 Ventilation, Temperature, Dust, Fumes etc.

Sec. 13 to 16, 36, 37 and Rules 18A, 19 to 29, 64, 65 and 102 deal with this subject.

Ventilation is necessary to remove excessive temperature, contaminants and carbon dioxide exhausted and to supply oxygen or fresh air in work places.

Factors affecting are: (1) Temperature of air in room (2) Air velocity (3) Temperature difference between inside and outside of rooms (4) Heat radiation (5) Humidity and (6) Clothing of the workers.

Room temperature @30 °C (80 °F), Air velocity @30 mt/min and Temperature difference @2 "C (3.6 °F), are comfortable. Decrease or increase in these limits may cause discomfort. Site (place), season, surroundings etc. may vary the limits.

Types of ventilation are (1) Natural and (2) Mechanical. Natural ventilation is the cheapest ventilation. Therefore, try .to minimise the walls, and partitions. Increase doors and windows. About 15% of floor area should be provided for natural ventilation. Select proper type of roof/false ceiling and cross ventilation. More open space should be provided in chemical and dangerous plants.

Up to a room of 60' or 18 m length or width sufficient natural ventilation should be provided but for an area greater than this mechanical or forced or local exhaust ventilation is necessary.

Exhaust fans. Man-cooler fans (throwing air on man). Hood, duct and blower. Air cleaning device. Air cooling (passing air through water) devices. Air-conditioners etc. are used as means of mechanical ventilation. This system may be of forced draft or induced draft (capture) type or Low volume High Velocity (LVHV) type. Proper design should be selected. Heat insulations like aluminium screen near furnace, lagging and cladding on pipes and valves etc. are also useful.

Height, type and material of roof and walls, separation of hot processes or parts, exhaust appliance near the point of origin of dust, fume, impurity etc., Hood & Chimney, Humidity control (S 15 & R 19 to 29), 500 cu. ft. or 14.2 cu. m. of space per worker (considering height upto 14' or 4.2 m only), manhole of prescribed size, precautions against dangerous fumes (S 36). Portable electric light (S 36A) and inflammable dust, gas etc. (S 37 and exemption u/r 65) should be adopted as per statutory provisions.

For details see Chapter-10.

2.5 Lighting and Colour:

Sec. II, 17, 35 and Rule 16, 30 to 34 and 63 deal with this subject. Sec. II (1) (d) requires that particular parts of a factory should be white washed, colour washed, varnished or painted in prescribed periods. Rule 16 states exemption to this.

Sec. 17 requires sufficient and suitable lighting, natural or artificial or both and prevention of glare and shadows.

Rule 31 describes standards of lighting (illumination) over interior parts of a factory in general and of a ginning factory in particular. Rule 32 describes measurements for prevention of glare. Rule 30, 33 and 34 are exempting rules to this lighting provisions. The schedule u/r 34 gives a list of exempted factories. Sec. 35 (b) and Rule 63 (b) requires protection of eyes from exposure to excessive light. Effective screens should be provided for welding, cutting and melting processes creating excessive light.

IS:6060 and IS:6665 prescribe lighting standards.

Artificial light is costlier than natural or day light. Their combination is known as "Twilight" which is frequently used in offices.

Lighting may be of four types

1. Direct or local lighting - on particular job or working.
2. Indirect lighting - through reflection.
3. Combination of direct land indirect lighting, and
4. Diffused lighting through shade (fixture) surrounding lamp.

Lamps near machines or job and portable lamps must have shades or shields. Light should also go to ceiling. Indirect and diffused light is desirable than direct light. Unwanted reflection should be directed away from eyes. Work tables, chairs etc., should be so placed that light from windows comes from sides.

Flameproof lighting should be provided in flammable areas.

Lamps are of three types - incandescent filament, tubular fluorescent and colour corrected mercury vapour lamps. They have different light qualities. Lighting fittings are also of various types. Proper selection is necessary.

Colour code is also important. White and light colours give more reflections of light than that by black and dark colours. Ceilings should be white or near white. Walls should have light colours like yellow, green etc. Floors may have dark colours, but not white as it may create glare by upward reflection of light. Shining aluminium colours on walls are not good as they may also cause glare. Furniture and equipment may have medium colours.

Different colours are used for safety precautions and as accident prevention signs. Colours on pipes are useful to distinguish them. Guards should be regarded as part of the machines and should be painted in the same colour as that of the machine. If they are to be distigvished bydifferent colour, it should not be too dark. Colours on machines/vessels should be light, cool and pleasant.

For Details see Chapter-9.

2.6 Drinking Water:

Sec. 18 and Rule 35 to 40 deal with this subject.

Drinking water centres (with such written boards) should be' provided at suitable points conveniently situated for all workers. They should not be within 20' or 6m from any washing place, urinal or latrine.

Quantity of drinking water should be 4.5 litres per worker per day. Water should be clean and readily available during working hours. Proper storage with cover is also necessary. It should be cleaned and renewed every day. Report from Health Officer is reuired.

In a factory employing 250 workers or mole, cooled drinking water should be supplied from March to November each year. Each floor should have one water centre and one centre per 150 workers up to 450 and one per 450 thereafter. Each centre should have 3 or more taps (fountains) at least 2' or 0.6 m apart, and shall have a trough to drain away the split water. A person with clean cloths to distribute water is necessary. For details see Rule 40.

All water centres and their distances should be shown clearly in plans.

2.7 Material Handling:

Sec. 28, 29, 34 and Rule 58 to 60A and 62 deal with this subject. Material handling means the techniques used to move, lift, shift, transport, store or distribute materials with or without the aid of mechanical appliances.

As per one old study, about 40% accidents, 36% production cost and 66% process time cycles are due to material handling. Automation may help to reduce these figures. It is of two types (1) Manual handling and (2) Mechanical handling.

Manual handling is carried out by persons alone or in group (team) or/and with the help of hooks, crow-bars, rollers, hand trucks (carts), wheel barrows etc. Methods of lifting and habits play an important role.

Mechanical handling is carried out by hoists, lifts and 'lifting machines' like overhead travelling crane, jib crane, crab winch, teagel, pulley block, gin wheel, transporter including power trucks and conveyors or runway and with the use of "lifting tackle" like chain slings, rope slings, rings, hooks, shackles and swivels.

All rails, tracks and passage-ways for all hoists, lifts and travelling cranes should be shown in plans with their layout, height, distance, railing or guarding and capacities.

For details see Chapter-15.

2.8 Pressure Plants:

Sec. 31 and Rule 61 deal with this subject.

Pressure plant means a' plant, machinery, vessels, air receivers, digesters, petroleum stills, Vulcanisers, sterilizers, kiers or equipment used in manufacturing process and operating at a pressure above atmospheric pressure and includes water sealed gas holder having a storage capacity of 5000 cu. ft. or 141.5 cu. m. but it does not include working cylinders of prime movers (i.e. engines), gas cylinders, Other vessels exempted u/r 61 and vessels under the Boilers Act, 1923.

All pressure vessels including reaction vessels and sizing cylinders with all fittings should be shown in plans indicating their height, distance, surrounding and capacities. Means of safety and escape near such plant should also be shown. A schedule indicating number and size/ capacity of safety valve, pressure gauge, stop valve, drain valve, pressure reducing valve, rupture disc., temperature indicator, manhole, inspection window and other safety devices should be given.

Effective measures should be provided to ensure that the safe working pressure will never exceed.

For details see Parts 9.1.5 & 15.5.1 of Chapter-18.

2.9 Fire Protection

Sec. 38, Rule 66, 66A and 67 deal with this subject.

Fire causes loss of or damage to person and property both. Therefore preventive and controlling measures for fire are most important. This should include training and regular drill for fire fighting also.

When Heat, Fuel or Oxygen meet, a fire occurs. Therefore try to segregate chances of meeting of these three factors. At the stage of design and planning for a factory, this basic concept should not be ignored. Mark and maintain safety distances.

'Fire Loads' should be calculated by considering total fire danger in the factory. For this, types of materials, their heat capacity, equipment, storage, pressure, temperature, radioactivity, electrical hazards, types of fire etc., are taken into account. Generally Fire Insurance people do this. Then depending upon this fire-load, fire-fighting water quantity and equipment are decided. As per example, if a fire-load is calculated as 40 cu. mt/min., it means, a water spraying capacity of 40 cu. mt/min is required at all fire points. Design for Emergency plan & Disaster plan, in case of heavy fire loads.

IS:2190 suggests suitability of different types of portable fire extinguishers for different classes of fire.

In addition to necessary fire extinguishers, automatic heat, flame or smoke detectors and alarms, fire hydrants, monitors, sprinklers, sprays, hose-reels, risers, drenches etc., are also useful. Provide and mark clearly fire-exits, fire escape stairs, fire warning, fire buckets and no-smoking notices. Utmost care should be taken in chemical factories.

Fire protection layout and schedule of equipment should be shown in plans. Stairway, lift-way and means of access and escape should be of fire resisting materials. Angle of fire escape stair should not be more than 45° from horizontal and it should be available within a distance of 150' or 46 m. along the line of travel for escape. In a ginning factory; two suitable earthen ramps or flights or stairs made of brick work or fire resisting material should be provided (Rule 66 & 67).

For details see Chapter-13.

2.10 Dangerous Operations and Processes :

Sec. 87 and Rule 102 deal with this subject.

Provisions of 27 schedules for 27 dangerous operations/processes under this rule are most important from safety point of view. They should be strictly followed. Applicable details should be submitted along with the plans.

Special fencing of machines and vessels, protective wears, exhaust draft, floor of work-rooms, cautionary notice, play-card, separation of process, air space, ventilation, pasting room, work benches, disposal of dust, gases and fumes, container of dross and lead waste, drying room, mess room, cloak room, washing and bathing facilities, storage and transport, flame-traps, fire extinguishers, escape of petrol, flame proof electrical fittings, blasting enclosure, separating apparatus, first-aid arrangements, mixing and filling with scoop, cocks and valves, manholes, disposal of waste, means of escape, air analysis, medical facilities, housekeeping, process hazards, instruments, protection of reaction mixtures, site, isolation of buildings, fire. resistant construction, dangers of ignition, static electricity, process heating, escape of materials, leakage of flammable liquids, empty containers, storage of combustible materials, pipe lines for inflammable liquids, packing of reaction vessels, vigorous or delayed reactions, examination, testing and repair of plant, alarm system, effluents, staging, entry into vessels, storage of acid-carboys, buildings, drainage, covering of vessels, substitute, enclosed system, protection against inhalation, measures against skin contact, labelling etc. are described in various schedules u/r 102. Necessary provision/arrangements should be shown in plans at proper places.

Schedules No. 12, 19, 20 and some others u/r 102 provide chemical details. First, Second and Third schedules, and Chapter-IVA under the Act regarding hazardous processes, permissible levels of some chemicals in work environment and notifiable diseases must be referred while planning.

Ordinary flooring tiles contain carbonates which react with acid. Therefore acid-resistant flooring is required where acid or alkalis are handled. Alkalis on flooring create slippery surfaces. Water showers should be provided to dilute the effects of acids and alkalis. Storage and handling of solid, liquid and gaseous chemicals should be done carefully. Sources of heat, ignition or spark should be kept away. Dangerous limits including threshold limit values (TLV) should not be exceeded. Auto controls and recorders should be provided to control high pressure, temperature etc., within their limits. Workers should be provided with necessary protective equipment.

A material safety data sheet in respect of each dangerous chemical should be supplied to study properties and hazard potential of chemicals. Preventive/Control measures should also be stated therein.

Air is the breath of life, its absence or contamination may cause death or disease". These contaminants could be dusts, fumes, gases, vapours, mists, fog, smoke, grass etc. Dust may be of silica, coal, asbestos, cotton etc. Methods of prevention are substitution, segregation, enclosures, exhaust ventilation general ventilation including natural and mechanical, wet methods, use of personal protective equipment, personal .cleanliness, warning and publicity, education and training, medical examination etc. Appropriate neutraliser/scrubber, column, condenser shall also be provided and shown in the plans.

Use of low flash point solvents, carcinogenic substances, benzene, xylene, toluene and other aromatic hydrocarbons and their nitro compounds/ halogenated derivatives, caustic, chrome process, nitro or amino process, pesticides and insecticides, phosphine, phosgene, crude oil, bleaching powder, aluminium powder, lead, mercury or arsenic compounds, heavy metals and all explosive or toxic materials should be done very carefully. Separate receivers should be provided for them. Solvent extraction plants using solvents like pentane, hexane, heptane etc., should be designed carefully. Sufficient means for fire protection including alarms should be provided. Special rooms for processes and workers should be constructed.

3 INDIAN STANDARDS AND NATIONAL BUILDING CODE

Various Indian Standards are available for considering safe design and layout of industrial buildings, plants and equipment. They are the good guidelines for all safety people. Some are mentioned below in Table 7.1 :

Table 7.1 : Indian Standards

No.	Title	I.S No.
1	Sectional List of Indian Standards on Safety	-
2	Sectional List of Indian Standards on Civil Engineering	-
3	Industrial plant layout	8091
4	Code of safe practice for layout of outside facilities in an industrial plant	8089

5	Safety requirements for floor and wall openings, railings and toe boards	4912
6	Structural safety of buildings : Masonry walls	1905
7	Structural safety of buildings : Loading standards	875
8	Structural safety of buildings : Shallow foundation	1904
9	Glossary of terms relating to doors	10428
10	Selection of , installation and maintenance of timber doors and windows	4913
11	Steel doors, windows and ventilators	1038
12	Steel windows for industrial buildings	1361
13	Industrial ventilation	3103
14	Industrial lighting	6665
15	Daylighting of factory buildings	6060
16	Steel Tubular scaffolding	4014
17	Fire safety of buildings (General) : Materials and details of construction	1642
18	Fire safety of buildings (General) : Electrical installations.	1646
19	Fire safety of industrial buildings : General storage and warehousing including cold storages.	3594
20	Installation and internal fire hydrants in multi-story buildings	3844
21	Safety code for handling and storage of building materials	7969
22	Fire resistance test of structures	3809
23	Code of practice for noise reduction in industrial buildings	3483
24	Industrial safety belts and harnesses	3521
25	Glossary of terms relating to corrosion of metals	3531
26	Recommended design practice for corrosion prevention of steel structures	9172
27	Code of practice for cathodic protection of steel structures	8062
28	Safety code for scaffolds and ladders	3696
29	Safety Code for construction, operation and maintenance of river valley projects.	10386
30	Standard colours for building and decorative finishes	1650

There are hundreds of such standards which may be selected from Title No. I & 2 above.

National Building Code

SP 7 - 1983 is a single code containing various IS on building construction in one volume. It contains regulations useful to various departments, municipal administrations and public bodies. It lays down provisions for public safety with regard to structural sufficiency, fire hazards and health aspects of buildings. Other subjects included are building requirements, materials, structural design, electrical installations, lighting, ventilation, air conditioning, lifts, acoustics, plumbing services, gas supply, safety of workers and public during construction and rules for erection of signs and outdoor display structures. It is also available in five groups as under :

Group 1 For architects
Group 2 For structural design engineers
Group 3 For construction engineers
Group 4 For building service engineers
Group 5 For plumbing services engineers

Following special publications are also relevant

SP 6 ISI Handbook for structural engineers (7 parts).
SP 10 Nomograms for thickness of masonry walls.

SP 16	Design aids for reinforced concrete,
SP 20	Handbook on masonry design and construction.
SP 21	Summaries of IS for building materials.
SP 22	Codes for earthquake engineering.
SP 23	Handbook on concrete mixes.
SP 24	Code for plain and reinforced concrete.
SP 25	Causes and prevention of cracks in building.
SP 27	Method of measurement of building works.
SP 33	Handbook on timber engineering.
SP 36	IS on soil engineering (2 Parts) for plumbing services engineers.
SP 41	Handbook on functional requirements of buildings.
SP 1650	Standard colours for building and decorative finishes. (Revision of IS:1650).

4 SITING CRITERIA

4.1 General Guidelines :

General Criteria for selection of location of industries are as under -

1. Land availability and its cost.
2. Raw material availability.
3. Labour availability.
4. Infrastructure availability.
5. Access to market.
6. Transport facilities.
7. Drinking and process water facilities.
8. Sewage and Drainage.
9. Place for solid and liquid waste disposal.
10. Interlinking with other plants.
11. Surrounding population density and distance from the public.
12. Distance from highway and railway and from transport centres.
13. Suitability of climate, environment and factors related to ecology, geology, meteorology, micro & macro biology.
14. Government policy advantages like subsidies, incentives and zoning (area reservation eg. SEZ) if prescribed.
15. Other techno-economic criteria.

Site of a nuclear plant poses potential hazard to surrounding public. Considering the magnitude and consequence of the worst scenario, its site should be selected.

Rules of zoning and town planning should consider above factors.

Some of these factors are explained below in brief.

Location: Plants producing or using highly explosive, inflammable or toxic substances in bulk should be located away from dense population. As per Section 41 A of the Factories Act, now, the Site Appraisal Committee shall examine the location of a hazardous factory.

From safety point of view increasing distance from the public reduces the effect of explosion, gas release and radiation on them. But real problem is increasing population in vicinity after establishment of a factory. Govt. should control them.

Climate: Study of prevailing winds is useful to decide location of offices and their air-conditioning air intakes, storage tanks, warehouses, drainage and waste disposal, direction of exhausted smoke, fumes, dust, gas etc., with respect to surrounding locality. Data of rain, flood, hurricane, temperature and other weather effects is also useful.

Terrain (land, topography) : If bridges over streams, ditches, etc., are necessary they should be fenced by handrails I m. high and intermediate rails. Natural structure like hills, mountains, sea or riverside, type of soil, mine, underground source etc. may be useful for special purposes.

Nature of Site : It should be large enough for safe layout with sufficient space for all buildings, roads, parking and storing areas, effluent treatment plant and future extensions. Minimum distances as per fire laws, explosive laws. and other laws must be considered. Scale relief models of the site in addition to maps are useful for pre-design and spotting potential safety problems. Soil testing should be carried out as per engineering advice.

Accessibility: Rail, road, river, sea and airport facilities should be ensured. Post and telegraph, telephone, fax. E-mail, internet etc. are useful for fast communications.

Environment: If air impurities and interaction of emissions .or sources of ignition etc. from adjacent sites are harmful, they should be considered. Noise and vibration due to neighbouring industries, transport vehicles, running trains, low flying aircraft should be considered.

Special environmental guidelines are given in Part 4.2 below.

General Provisions: Adequate water supply for drinking, process and fire fighting, drainage of rain water, process water, fire water etc., and water /air/ land pollution problems must be considered.

4.2 Environmental Guidelines :

Rule 5 of the Environment (Protection) Rules, 1986, gives following siting criteria to be considered by the Government while prohibiting or restricting the location of industries in different areas

1. Standards for quality of environment laid down for an area.
2. Maximum- allowable limits of pollutants (including noise) for an area.
3. Likely emission from the proposed industry.
4. Topographic and climatic features of an area.
5. Biological diversity of the area to be preserved.
6. Environmentally compatible land use.
7. Adverse environmental impact likely to be caused by the industry (EIA is required).
8. Proximity to a legally protected area.
9. Proximity to human settlements.
10. Any other relevant factor.

Procedure for prohibition or restriction is also given in above rule.

Site Appraisal Committee u/s 41A of the Factories Act, while considering any site application, may go through above criteria.

The Industrial Policy Statement of July 1980, recognised the need for preserving ecological balance and improving living conditions in the urban centres of the country. On the basis of this Policy,' indiscriminate expansion of the existing industries and setting up of new industrial undertakings within the' limits of metropolitan cities and the larger towns are restricted.

To prevent air, water and soil pollution arising out of industrial projects, the Industrial Licensing procedure requires that the entrepreneurs before setting up the industry should obtain clearance from Central/ State Air and Water Pollution Control Board. In respect of certain industrial development projects it is. not only necessary to install suitable pollution control equipment but also to identify appropriate sites for their location.

Following conditions are also to be fulfilled :

1. The State Director of Industries confirms that the site of the project has been approved from environmental angle by the competent State Authority.
2. The entrepreneur commits both to the State Government and Central Government that he will install the appropriate equipment, implement and the prescribed measures for the prevention and control of pollution.
3. The concerned State Pollution Control Board 'has certified that the proposal meets with the environmental requirements and that the equipment installed or proposed to be installed are 'adequate and appropriate to the requirement.

The entrepreneur will be required to submit half-yearly progress report on installation of pollution control devices to the respective State Pollution Control Boards.

Depending on the nature and location of the project, the entrepreneur will be required to submit comprehensive Environmental Impact Assessment Report, and Environmental Management Plans.

Refer the latest EIA notification from the MoEF.

Siting Guidelines:

In a selected site, the following factors must be recognised.

1. No forest land shall be converted into non-forest activity for the sustenance of the industry.
2. No prime agricultural land shall be converted into industrial site.
3. Within the acquired site the industry must locate itself at the lowest location to remain obscured from general sight.
4. Land acquired shall be sufficiently large to provide space for appropriate treatment of waste water still left for treatment after maximum possible reuse and recycle. Reclaimed (treated) wastewater shall be used to raise green belt and to create water body for aesthetics, recreation and if possible, for aquaculture. The green belt shall be ½ km wide around the battery limit of the industry. For industry having odour problem it shall be a. kilometre wide.
5. The green belt between two adjoining large scale industries shall be one kilometre. Green belt should also be provided within factory premises.
6. Enough space should be provided for storage of solid wastes so that these could be available for possible reuse.
7. Layout and form of the industry, that may come up in the area must conform to the landscape of the area without affecting the scenic features of that place.
8. Associated township of the industry must be , created at a space having physiographic barrier between the industry and the township.
9. Each industry is required to maintain three ambient air quality measuring stations within 120 degree angle between stations.

4.3 Meteorological aspects :

While selecting a site, climatic conditions should also be considered. It should not have any adverse effect on industrial processes otherwise more control measures may be required. High or law temperature, more moisture, high or low wind velocity, frequent raining, cloudy atmosphere, Infrequent changes in weather condition, effect of nearby seashore, effect of hills and jungles, effect of long time sunrays etc. have considerable effect on raw materials, products and processes. Gas leakages from industry, their concentration and damage distances vary depending on weather conditions.

Global warming and green house effect should be decreased by preventing emissions of CO_2, and O_3, depliting substances.

MoEF guidelines provide further information.

4.4 Seperation Distances :

Separation distances (safety distances to be maintained) suggested by the Government guidelines are as under :

In siting industries, care should be taken to minimise the adverse impact of the industries on the immediate neighbourhood as well as distant places.

Some of the natural life sustaining systems and some specific land uses are sensitive to industrial impacts because of the nature and extent of fragility. With a view to protecting such industrial sites, the following distances from the areas shall be maintained:

1. Ecologically and/or otherwise sensitive areas: at least 25 km; depending on the geo-climatic conditions the requisite distance shall have to be increased by the appropriate agency.
2. Coastal Areas: at least Vi km from high tide line.
3. Flood Plane of the Riverine Systems: at least ½ km from the flood plane or modified flood plane affected by dam in the upstream or by flood control systems.
4. Transport/Communication System: at least ½ km from highway and railway.
5. Major Settlements (3,00,000 population) : distance from settlements is difficult to maintain because of urban sprawl. At the time of siting of an industry if any major settlements notified limit is within 50 km, the spatial direction of growth of the settlement for at least a decade must be assessed and the industry shall be sited at least 25 km from the projected growth boundary of the settlement.

Separation distances are either between two units or a single unit and a source of ignition. It is normally between the adjacent edges of the units and not from centre to centre.

Factors to determine separation are (1) Explosion effect (2) 'Radiant .heat from a burning material (3) Ignition of a vapour escape and (4) Heavy concentration of a toxic gas.

Normally 15m (50 ft) is suggested for the storage of petroleum products excluding LPG. For LPG a smaller distance is allowable if radiation walls and/ or water drench systems are provided. From an ignition source, for ethylene storage, 90 m is suggested for pressure storage and 60 m for refrigerated storage. Risk of failure of a pressure storage is higher than that of refrigerated storage.

Mecklenburgh (1973) suggested 15 m distance from process units, furnaces, boilers, effluent plants and loading areas and 30 m from cooling towers, gasholders and flare stacks to adjacent process units, main roads or site boundary.

Some suggested distances are as under:

No.	Unit	Separation Distance (mt)
1	Flammable liquid, low to medium pressures	10-25
2	High flammability, high pressure	35-50
3	Direct fired boilers and furnaces	35-50
4	Blow down stack with flare	40-75
5	Loading facility	35
6	Public roads and railroads	35
7	Cooling towers	35
8	Storage tanks	25-50

ILO guidelines (see reference No.7) suggest following table of approximate separation distances for **Major Accidents Hazard works:**

Table 7.2 : Separation Distances for MHA units :

Chemical	Largest tank size (tonne)	Separation distance (mt)
LPG at >1.4 bar absolute OR Flammable gas or moisture at > Boiling Point	25-40 41-80 81-120 121-300 >300 25 or more cylinders or tank up to 5t	300 400 500 600 1000 100
LPG, refrigerated, at ? 1.4 bar absolute	50 or more	1000
Flammable gas or mixture	15 or more	500
Flammable gas or Mixture having BP<0^{o}C, refrigerated or cooled at ? 1.4 bar absolute.	50 or more	1000
Liquid or mixture of liquids having Flash Point < 21^{o}C	10000 or more	250
HF SO2 SO3 Acrylonitrile HCN CS2 Chlorine Bromine H2 Phosgene Methyl isocynate EO, or Propylene oxide (ambient pressure) Liquid O2 Ammonium nitrate – bagged in stacks of	10 or more 20 or more 15 or more 20 or more 20 or more 20 or more 10-100 > 100 40 or more 2 or more 2 or more 1 5-25 > 25 500 or more 300 t	1000 1000 1000 250 1000 250 1000 1500 600 500 1000 1000 500 1000 500 600

$$600\left[\frac{\text{stack size (t)}}{300}\right]^{\frac{1}{3}}$$

- Loose distance =		

In above separation distances no restriction category B development, category C restricted and within about 2/3 of the distance, category A is restricted. Categories are as under:

Cat A - Residential houses, hotels, flats.
Cat B - Industrial, factories, warehouses.
Cat C - Special, schools, hospitals, old peoples' homes.

These distances are tentative and may be slightly modified under local circumstances. If they are found unacceptably large, quantified risk assessment (QRA) should be carried out to assess distance.

Instead of using such fixed distance criteria, another approach is to calculate the hazard range by using formulae for gas dispersion or fire/explosion effect.

See Table 2 & 3 for safety distances under the Petroleum Rules 2002 for petroleum tanks.

Because of the shortage of space, it may not be possible to maintain an ideal separation and in that case, the decision should be made with safety considerations.

Diversion walls can be used to divert vapour flows to a safe area. Firewalls can be used: to protect from radiant heat and explosion (blast) wall to protect from the impact of explosion. Steam curtains or drenches are used to provide separation from fire or ignition. ..

5 NEED FOR PLANNING AND FOLLOW UP

5.1 Need and Approach:

Need of planning for safety and health and 'safety engineering approach in design, planning and construction of new plant or new alteration or addition' are basic and most essential, because:

1. General efficiency and safety in industrial activities can be greatly increased thereby.
2. Accidents and occupational diseases can be prevented from the earliest days.
3. Cost saving factors can be considered by effective use of floor area, providing ample space for men, materials and machines, reducing the cost of material handling, reducing the time of work or process and making efficient use of resources, personnel and equipment etc.
4. Efficient flow of work is maintained, and
5. Safety and comfort of people are achieved by considering ergonomic aspects.

Therefore safety and layout engineer must take into account :

1. Products and product layout
2. Raw materials, processes and their layout
3. Size and type of site and building.
4. Machinery, vessels and equipment required.
5. Assessment of manpower required.
6. Relationship between departments.

7. Process flow chart.
8. String and flow diagrams.
9. Templates and scale models.
10. Drawings and plot plans, and
11. Travel chart etc.

5.2 Follow up :

As need for planning is important, follow up action according to that planning is equally important. Without follow up no planning can be executed. Therefore distinct responsibilities should be assigned to different persons to implement the follow up actions of every stage or step decided in planning. It should be reported to the higher officer, feed back should be received for correction or addition if any and the work should be completed within a stipulated time. All points of safety, health, environment and ergonomic factors should be included from the built-in stage. If this follow-up is missed in the initial stage, later follow-up may become continuous and costly.

6 PLANT DESIGN AND LAYOUT

6.1 Components in Design Process:

If components of any structure, vessel, equipment etc. are weak or not properly designed, they may fail. Therefore a component should-be designed to withstand (1) static loads (2) dynamic loads (3) internal and external pressure (4) corrosion & erosion 11(5) loads due to large differences in temperature / pressure and (6) loads due to external impacts (wind, settlement, earthquakes etc.).

Selection of proper "factor of safety' and proper material of construction (MOC) are important form design point of view.

These loads may be included in the design process. It is of more importance for pressure plant containing flammable, explosive or toxic substances or liquids above their flash points or boiling points.

Components of control systems (manual or automatic) should be properly integrated with necessary safety devices, trips and alarms, interlocks, pressure reducing valve (PRV), non-return valve (NRV), excess flow valve (EFV) and automatic process controllers etc.

Reliability of components of main and sub-systems (parts) is important. See Part 5 of Chapter-19 for reliability aspect.

Load and pressure testing of components i.e. testing of the assembled systems, piping and joints, valves and fittings is also necessary.

6.2 Travel Chart:

Travel chart is a simple and useful, method to analyses deficiencies in the layout of a factory and in planning a good layout.

The deficiencies in a poor layout are :

1. Congestion on the shop floor.
2. Excessive waiting time of machines and materials.
3. Poor space utilization.
4. Absence of easy access to machines, tools and materials.

5. Excessive handling of materials.
6. Irregular flow of process and materials.
7. Back tracking and zigzag movements.
8. Absence of necessary aisles and routes.
9. Unbalanced activities resulting in poor utilization of men, machines and materials, and
10. Inflexibility of layout allowing no scope for expansion or alteration needed with time.

The travel chart technique detects above deficiencies to improve the plant layout and suggests follow-up action necessary. It is a mathematical approach which measures quantitatively the movements of materials and in-process work. The purposes of such measure are:

1. To assess the quantities and the nature of materials flowing from area to area and from machine to machine.
2. To reduce movements to minimum. .
3. To relocate contributing and user areas on the basis of percentage contribution, and
4. To arrange operations in each section for self sufficiency.

Unit movement is noted by multiplying distance and frequency. From the data of number of components, their weights, distances travelled, frequency of trips etc., templates for the machines and equipment and other details, the travel charts are prepared.

The .study of travel chart suggests improvements in materials handling methods and machines in operation, types of containers, aisles, travel routes etc.

6.3 Planning, Design and Layout :

Plant or factory premises vary in size and manpower employment. There are giant petrochemical and fertiliser plants on one end and small factory in a single room on the other end. Under the Factories Act, more welfare facilities are required from bigger factories depending on number of workers arid male-female employment. Stringent safety provisions are applicable to chemical plants and major hazard (MAH) installations. Before starting a factory permission from local authority and other related government departments is also required. Where pollution is possible, permission from State/Central Environment Department and Pollution Control Board is also necessary.

Definition of a 'factory' is given under the Factories Act 1948 and it is the main Act (together with State Factories Rules) applicable to the layout, design, construction and working of a factory.

A plant should be located after considering siting criteria mentioned in Part-4, and be constructed by considering statutory requirements mentioned in Part-2.

6.3.1 General Principals of Planning and Design

They are as under :

1. Siting criteria as mentioned in Part 4.
2. Good transportation facilities.
3. Safe handling and storage facilities.
4. Personal and Welfare facilities.
5. Engineering, utility and safety facilities.
6. Walkway, stairs, .platform, ramps etc.
7. Good lighting and ventilation.
8. Elevators and lifting machines.

9. Boilers and pressure vessels.
10. Fixed and portable machinery and equipment.
11. Electrical installation.
12. Fire protection.
13. Other provisions for health and safety, viz. effluent disposal, water, firs-aid, emergency power, equipment and emergency planning etc.

General principles of any workplace design:

They are as under

1. Plan the ideal, then the practical.
2. Plan the whole, then the detail.
3. Plan the work process and equipment around the system requirements.
4. Plan the workplace layout around the process and equipment.
5. Plan the final enclosure around the workplace layout
6. Use trials to evaluate alternatives and to check the final design.

Design aspects should include proper buildings and roads layout, storage & process layouts, proper heights, lights, depths, spacing and dimensions considering ergonomic requirements, loads and climatic factors and specific process hazards.

Some notable points for good planning and design are:

Sound foundations, stable construction and loading, non-congested machinery layout (safety distance 1 m), no overcrowding (otherwise claustrophobia is possible), minimum floor area per worker (1 to 2 m^2), minimum alley width, safe roadways, walkways, yards etc., prescribed ventilation area (15% of floor area), sufficient natural and mechanical ventilation, humidity control, sufficient natural and artificial lighting, open plant for chemical processes, dykes, boundaries and blast walls (to' withstand 7 kgf/cm^2 force), safe layout and erection of chemical vessels and equipment, ergonomic considerations, segregation of noisy and dusty processes, fencing and covering of water-ways, reservoirs, ditches, floor openings, gutters etc., separate entrance and exit gates, parking plots, safe layout of control room, provision of fire prevention and protection systems, safe storage of flammable, explosive and toxic materials, waste disposal T arrangements for solid, liquid and gaseous wastes, ; effluent treatment plant (ETP), scrubbers, incinerators, flare or exhaust as per requirement, safe : discharge of smoke, fumes, dusts, gases etc., ' maintenance of separation distances mentioned in Part-4.4, proper layout of utilities (water, power, steam, air, oil, inert gas etc.) and ancillary services, : safe transportation and security arrangement, hazards identification and removal, safe pipe work, follow-up of standards, codes and reliability criteria, \ limitation of inventory, fail-safe design, built-in safety devices etc.

Thus points of plant layout and design are numerous and selection of particular point depends on process, technical and safety requirements.

6.3.2 General Principals of Plant Layout

General Layout: Size, shape, location, construction, buildings layout and other facilities should permit efficient utilization of machines, processes and materials. Need and possibility of one storey or multi-storey structure should be decided.

Layout should be properly planned to allow smooth flow and efficient use of men, materials, methods, processes, time cycle etc. and should allow good and .safe working conditions to prevent any accident or risk.

Some General Principles for good Layout arc:

1. Enough work space (2 m2 per 'person) should be provided for workers to work without restriction.
2. Proper roads, walkways, tracks, alleys, catwalks etc. should be provided for free passage of men and materials to avoid delay and obstruction.
3. Sufficient doors, windows, ventilators and open space must be provided for good ventilation and lighting.
4. Installation of machinery, floors, stairs, lifting machines, electric wiring etc. must be done to ensure safety. Allow at least I m space around each machine.
5. Keep the handling of materials to the minimum. Use mechanical means to reduce manual strain.
6. Provide safe means of access to all work places.
7. Provide safe transport facilities for men and materials.
8. Provide adequate emergency exits.
9. Purchase and arrange in orderly manner machines and equipment with built-in safety.
10. Isolate high noise, vibration, fire, explosion and toxic hazards. Design a work bench, table, booth, roof, ladder, platform, sheet, support etc. with safety standards to avoid such hazards.
11. Allow space for future expansion.
12. Provide repair and maintenance workshop, welfare facilities and education and training facilities.
13. Use appropriate colours, notices, signs, labels, posters etc. for safety.
14. Provide easy locations of fire alarms, fire fighting equipment, personal protective equipment, emergency assembly points, medical centre, safety office etc.
15. Provide and maintain good housekeeping.

Other factors of plant layout and design from safety point of view are:

1. Safe design and construction using safety standards and good engineering practices.
2. Statutory requirements for plant layout and design.
3. Containment of leakage and accidents.
4. Segregation of different risks.
5. Safe storage, process, utilities and waste disposal design.
6. Safe control room location & design.
7. Emergency control devices.
8. Fire fighting and gas leak control facilities. Ample water storage.
9. Auto controls, alarms, trips, interlocks and necessary safety devices.
10. Railings and guarding at chances of fall, cross over and on moving machinery.
11. Roads of sufficient width and signs.
12. Safe loading, unloading, transport and piping facilities.
13. Security round the clock.
14. Wind direction and speed indicator with recorder to know wind direction and speed.
15. First aid centre and ambulance van.

The site layout is prepared first, then the plot and equipment layouts. Site is subdivided into blocks or plots. Equipment layout includes P & I diagrams and fire equipment layout. This is as under –

Plant layout

- Site layout
  - Preliminary layout
  - Main layout
  - Segregation
  - Separation distances
  - Fire containment
  - Services/ Utilities
  - Effluents
  - Transport of materials
  - Emergencies
  - Security
- Plot layout
  - General considerations
  - Hazards
  - Fire fighting
  - Escape
  - Construction
  - Operation
  - Maintenance
- Equipment layout
  - General considerations
  - materials
  - P.&I. diagram
  - Fire equipment layout

6.4 Factory Building and Internal Layout

IS:875, 1904 and 1905 for structural safety and IS:8089 and IS:8091 for layout safety are important.

For approval of drawings under the Factories Act and Rules see foregoing Part 2.

Location of Buildings : Segregation of raw material storage, process building, finished product storage and storage of hazardous materials, flame or ignition sources is necessary. Statutory specifications for storing flammable liquids shall be followed. Fire resistant wall is required between flameproof and non flame proof area. A detailed flow sheet shall be used for layout. The cross flow of materials and/or pedestrians should be minimised.

All buildings and parking plots should be located near periphery to limit internal traffic. The entire parking area should be fenced. White lines 10 to 15 cm wide, standard stalls of 5 m x 6 m, driveway of 8 m, for two-way traffic and unobstructed viewing are desirable. Separate entrances for incoming and outgoing vehicles and night light of about 100 lux m^2 at a height of 1m should be provided. Buildings having more people should be away from hazardous areas. Production building should have roads and access for fire fighting, maintenance, vehicles, lifting machines etc. The flow of materials should be such that its length of travel and frequency of handling are minimised. Cooling towers should be so located to minimise mist and ice hazards.

Ventilating, heating and air-conditioning are needed for personal comfort and sometimes for process conditions. Extra ventilation should be provided where heat or bad fumes are generated. Boilers, fans and air-conditioning equipment should be located in separate rooms for their fine adjustment and confinement of noise. Boilers should receive adequate air and combustion by-products should be exhausted safely. Location of incinerator should ensure that negative pressure differential in a building does not cause an incinerator stack to serve as an air source.

Space for storing supplies, tools, frequently used equipment, racks, bins, shelves etc: should be provided. Waste storage and additional required facilities should also be considered.

Rail, Road and Footpaths: Good design for railway sidings is necessary. Provisions for piping, valves, pumps, derails etc. to unload or load tank Wagons, guarding of side track and public thorough fares and clearance (distance) from main plant are necessary.

Roads should be carefully laid out, substantially constructed, well surfaced, drained and kept in good condition. Road should be at least 11 m. away from buildings. Heavy duty truck hauling requires road up to 16 m. wide for two-way traffic with ample radii curves. Gradient up to 8% and slight crown for drainage with ditches to carry off water are necessary. Traffic signs, markings, speed breakers should be provided. Good footpaths with shortest distance should be .provided to discourage short cutting Concrete is preferred for footpaths.

Floors, Platforms and Catwalks: The floor area should be sufficient to allow men, machines and materials without any obstruction and overcrowding. As per Section 16 of the Factories Act, 14.2 m^3 breathing space per worker limited to a height of 4.2 m is necessary. The minimum floor area per worker in power and non-power factories should be 3.3 sq. m. (36 sq. ft.) and 2.3 sq. m. (25 sq. ft.) respectively. Minimum roof height should be as mentioned in Part 2.1(A). The floor should be non-skid type of sound construction, easily cleanable, free from moisture retention and well maintained. Other factors of floor viz. load bearing (strength), durability, noise, drainage, resilience, appearance, light reflection, dustiness, chemical composition and reaction, heat and electrical conductivity and maintenance should be considered for proper selection. Marble, slate, asphalt, tile, linoleum, cement and wood are reasonably safe, provided their surfaces are properly maintained. Welding floor should be of noncombustible material. Spark-proof and conductive flooring such as magnesium and conductive rubber are good where flammable air mixture is likely to be ignited by a friction or static charge.

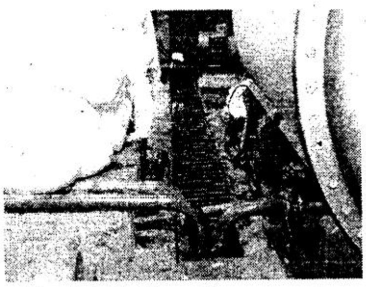


Fig. 7.1 Grill on floor opening

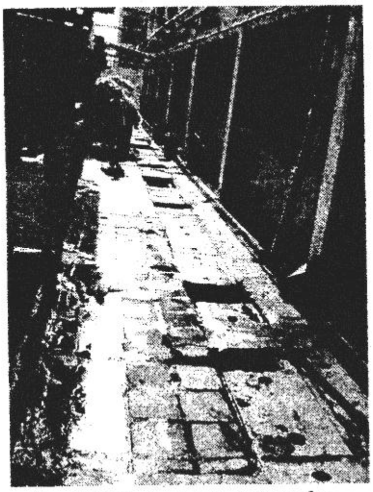

Fig. 7.2 Gutter not properly coverd

Floor openings and floor holes, wall opening and wall holes, open-side floors, platforms and catwalks shall be guarded with railings and guards as mentioned in IS:4912. General height of railing is 100 cm maximum and 75 cm minimum with minimum distance between its members (posts) as 20 cm and capable of withstanding a point load of at least 90 kg in any one direction. Floor covers should withstand a truck load of 9 to 15 tonnes.

The gangway should be at least 1 m wide and firm to withstand movement of a trolley, hand truck. Catwalk is a passage way for persons elevated above the ground or any floor level such as foot walk along shafting or a walkway between buildings. Every catwalk should be al least 42 cm wide and guarded by a **tow guard** (a vertical barrier erected along exposed edges of a floor opening, platform, -catwalk, ramp etc., to prevent falls) of 15 cm nominal height. Ramps slope should not be more than 15°.

Fig. 7.3 Catwalk, tow guard and railing

Stairs, ladders and Scaffolds: Stairs are safer than ladders. Circular stairways should be avoided. Stairway slope should be 30° to 35° from the horizontal. The maximum height of a staircase should be 3.7 m (12') with riser height between 13 cm to 20 cm and tread width 23 cm (9") or more. The width

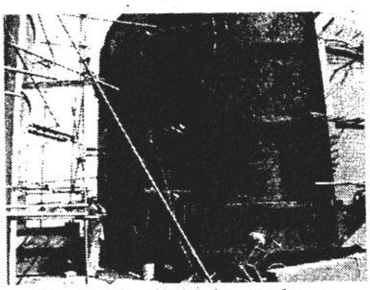

Fig. 7.4 Scaffold for tank

of the staircase should be 1.12 m (44") or more and load bearing i strength of 500 kg./sq. I m. (100 lb./sq. ft.). Two \ distant staircases are j needed at hazardous

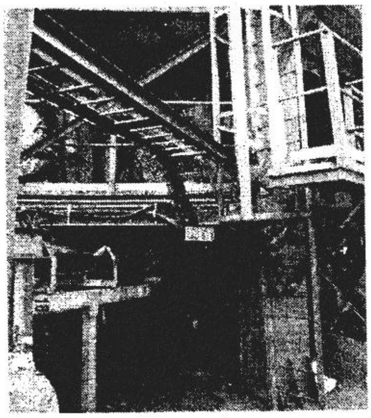

Fig. 7.5 Ladder and Monkey ledder

Scaffold and its supporting members should be designed to support a given load with a factor of safety at least 4 No plank less than 5 x 25 cm should be used for scaffold plains. Their overlap distance should be at least 30 cm. Tubular steel scaffolds designed, tested and built by experts are more preferable over built-on-the job wood scaffolds. Their advantages are: safety of worker, lower cost, lowered fire hazard and good appearance. 15:2750, 3696 and 4014 are on scaffolding.

Exit, Doors and Windows: Maximum distance between two exits should be 20m in high hazard factories and 30 to 50m in low hazard factory. They should be as per requirement. Exit doors should be clearly visible and open outwards. The standard size for a door and window are 200 x 120 cm and 150 x 90 cm respectively. A sill level of a window from working floor is 1 m. For every 9.35 sq. m. (100 sq. ft.) wall area one window of standard size should be provided. Normal distance between two windows (centre to centre) should not exceed 2.4 m. (8'). The window shutters should also open outwards. Ventilators should be provided SOT a height above 3.5 m.

Stores: Mechanical handling should be preferred. All bunds or dykes should have good drainage. Local stores and stocks should not cause obstruction. Inventory and site of hazardous materials should be limited. Stocks, racks, shelves, stacks, electrical machinery etc. should be protected from rain or water.

Loading-unloading should be so located to minimise disturbance to traffic. Storage of explosive, reactive, unstable, flammable and toxic materials should be so designed to maintain sufficient distances within the storage area and between other areas. Maximum limit per unit area should be decided so that if larger quantities are to be stored, new store area well separated from the first may be provided.

Safe storage of flammable, explosive, toxic and radioactive materials should be ensured. Flameproof electric fitting, fuming (low Boiling Point) chemical in AC room, closed (pipe) transfer, safe pumping, local exhaust etc. are necessary.

See also foregoing Part 2 and Rule 66(1), GFR, for storage safety of material.

See Chapter-16 for working at different levels.

Engineering workshop: Clear gangways around dangerous machines, separate welding bays with shielding, ventilation and fume extraction, outside racks and chains for gas cylinders, permanent lifting gear at correct place for all foreseeable loads, machine to machine or machine to wall distance of at least 1 m., clothing and tool cupboards, and first-aid box etc., need good planning.

Layout of equipment: Various methods are used to determine the safest and efficient layout of production machines and equipment. Threedimensional models made to scale can be rearranged on a scaled floor plan to determine such layout. Congested area should be anticipated and avoided. A vertical distance of at least 2.2 m is generally specified between passage stairways and overhead structures to provide ample clearance (head room). Overhead cranes and conveyors require at least 60 cm of vertical and horizontal clearance. Aisles for two-way traffic should be more than I m wider than twice the width of the widest vehicle. For heavy traffic, aisles from 4 to 6 m wide are specified. Aisles should have a 2 m radius for truck turn and should have no blind corners. Where ramps are needed, a I m wide walk-way should be provided.

All hot parts should be lagged to avoid burns. Operations of ignition sources (welding-cutting etc.) should be located away from use or store of flammable materials. Toxic operations should be kept away from a populated area.

Electrical Equipment: Complete metal enclosed unit substations should be installed and grounded. Oil-filled transformers may give off flammable gases which should be safely discharged. Non-flammable transformers are desirable near flammable area. Short circuit protective devices should be large enough to carry the maximum short circuit current. Circuit breakers, fuses and safety switches should not fail. Grounding system should be capable of conducting earth leakage current. Battery room should be isolated and well ventilated. Automatic -CO injection system helps to extinguish electrical fire. There should be sufficient sections to allow maintenance without shutting down the whole system. Metal enclosures should be grounded. Cable circuits should be enclosed in rigid conduit or interlocked armour cable. Metal enclosed plug-in-bus-ways are desirable for machine tools. Three wire systems with one ground wire for all electric equipment are necessary. Electric shock guards (ELCB) are also desired.

Others: Laboratories with fume cupboards and selected flooring, offices with proper layout, safe rack, shelves, height and designed furniture, canteen, lunchroom, rest room, cloak room, creche, ambulance room etc., should be as per statutory requirements. ETP and waste disposal plant should be provided from beginning.

All gutters, reservoirs, waterways, ditches in or near the factory should be fenced to prevent fall.

Underground rooms should have sufficient lighting, ventilation and proper height (> 3 m). Fumes generating process is not allowed therein.

For good housekeeping, lighting & colour, ventilation & heat control, electrical safety, noise & vibration, fire & explosion, machine guarding, material handling and working at different levels see Chapter-3 to 16 respectively.

6.5 Standards and Codes of Practice for Plant and Equipment:

See foregoing Part-3 and Table 7.1 for Indian Standards for plant construction.

While referring to standards and codes, it is useful to understand following definitions:

1. A criterion is any rule or set of rules that might be used for control, guidance or judgement.
2. A standard is a set of criteria, requirements of principles.
3. A code is collection of laws, standards or criteria relating to a particular subject, such as the National Building Code, National Electric Code, National Fire Code etc.
4. A regulation is a set of orders or rules issued to control the conduct of persons or manufacture within the jurisdiction of the regulatory authority e.g. Indian Boiler Regulation (IBR).
5. A specification is a detailed description of requirements, usually technical.
6. A practice is a series of recommended methods, rules or designs, generally on a single subject. Design handbooks, guides or manuals contain non-mandatory practices, general concepts and examples to assist a designer or operator.

Standards are based on necessary tests and requirements. They give assurance about soundness, quality, durability, reliability, safety etc. Design standard.s give sound criteria for safe design. Quality standards indicate proper material or product. Codes and Standards for pressure vessel design provide correct method of construction and testing. Standards may be mandatory or voluntary. Test standards are set and, used for testing and certification of products. Indian Standards on safety are available on thousands of Hems.

Codes of practice are generally followed where no statutory provisions are available or where missing details are required. On hundreds of 'items of manufacturing there may not be any legal standard. In that case code of practice should be followed.

In designing foundation work for any building, in designing and construction of steel structure, vessels, piping, supports, equipment etc., safety standards and codes should be followed. BIS (Bureau of Indian Standards) Handbook - 1996, gives 14357 standards of which some examples are given in Part-3, Table 7.1. Many 'Safety Code for ....' are given in alphabetic index of this handbook. Some examples are given below in Table 7.3.

Table 7.3 : Code of Practice & Safety Codes (IS)

Code of Practice for…	**IS**
Architectural and building drawings.	962
Day lighting of buildings	2440
Demolition of buildings	4130
Design & construction of floors & roofs	14215
Design & construction of steel chimney	6533
External hydrant system	13039
Fire safety in hotels	13716
Fire safety in iron & steel industry	13694
Galleries and opening in dams	12966
Laying mastic flooring in LPG industries	13074
Manufacture of safety books & shoes	13295
Measurement of civil engineering works	3385
Structural safety	13063
Super capacity bucket elevator	12941
Safety Code for….	**IS**
Body Protection	8519
Chemical Laboratory	4209
Colours and signs	9457
Concrete framed structures	8989
Conveyors	7155
Electro heat installation	519
Footwear for steel plants	10348
Industrial radiography	2598
Working with construction machinery	7293
Handling and storage of building materials	7969
Hot bituminous construction	5916
Layout of industrial plant	8089, 8091
Plant railways	8218
Powered industrial trucks	6305
Conditions for woodworking machines	8964
Data processing equipment	10422
Devices for gas cylinder	5903
Equipment, eye, face, ear	8520, 8940
Foot & Leg	10667
Glove, industrial	6994
Masonry walls	1905

Nets, industrial	11057
Structural loading	875
Hand tools	8235
Scaffolding, steel	4014
Relief valves	3233
Shallow foundations	1904

For ISO 14001 and OHSAS 18001 See Part 1.17 of Chapter 19.

7 ERGONOMIC CONSIDERATION FOR PLANT DESIGN AND LAYOUT :

Important ergonomic factors to be considered in plant layout and design include :

1. Free space (80 to 100 cm) around each machine for easy and safe movement.
2. No overcrowding. Breathing space of 14.2 m" per worker (max height 4.2 m).
3. Ventilation opening -15% of the floor area minimum. Window bottom height I meter or less from the working floor for natural ventilation.
4. A traversing part or materials carried by machinery should not approach within 50 cm (Sec. 25 of the Factories Act prescribes 45 cm) of any fixed structure which is not part of the
5. Suitable platforms, safe means of access and lifting appliance suspension points should be provided to facilitate cleaning and maintenance
6. Height and position of seats, valves, gauges, indicators, displays, meters, knobs, controls, handles, switches, push buttons, brakes, notices etc. should be suitable to the operators. Safe manual lifting' methods should be utilised.

Types of ergonomic design are as under:

No.	Type	Includes
1.	Work-space design	Seat, bench or console (control or comfort) design, positions of controls, displays & materials, operator's body, data and their working models including computer graphics.
2.	Environmental design	Light, ventilation, heat, humidity, noise, vibration etc. comfortable to the operator.
3.	Work time or situation design	Working hours, intervals, shift schedule and inter-personal aspects of work.
4.	Interface design	Exchange of information between man and machine or environment e.g. display gives and control receives information. Proper design of such displays (pointers, letters, numbers, figure etc.) and controls (knobs, brakes, switches, size, shape, position, forces etc.) most convenient to the men.
5.	System design	Allocation of function / job between man and machine and procedure. New techniques to understand limitations of each other and to fill the gap by the best design.

All these areas overlap and are interrelated. The main object of such ergonomic design is to get long term gain with no adverse effects on health and safety and to minimise human errors, efforts, stress and strain and ultimately risks and accidents.

Workplace design calls for following ergonomic factors :

1. Standing position offers more mobility, more arm strength application, less front-to-rear room, no seat and greater latitude in workstation design.

2. Sitting position offers forceful pedal operation, less fatigue-, precise vision.

3. Work object or job position should, be close to the front edge of the work surface to avoid more bending or leaning.

4. Sufficient room for hands and feet movement with footrest and backrest to work while sitting.

5. Visual displays should be in front of the body and below eye level so that the line of sight is declined 10 to 40 degree below the horizontal level.

6. Avoid holding time of work piece or hand tool to minimise muscle tension.

7. Use lever mechanism to apply less force. Take advantage of mechanical design, appliance, equipment, instrument etc to reduce manual work. '

8. Foot controls for seated operator, soft floor (e.g. rubber mat) for standing operator, adjustable chairs to maintain proper siting height, permitting posture change to avoid fatigue, allowing sitting/standing alteration and enough space for working are all to be considered in ergonomic design.

9. Computer operators have posture and vision complaints, e.g. musculoskeletal pain & discomfort, eye strain and fatigue. Studying the position, furniture, equipment, lighting etc. should be redesigned. Upright trunk and neck position, forward-declining set surface, properly shaped backrest and properly placed controls and displays are necessary.

See Part 13.4.4 of Chapter 5 and Part 3 of Chapter 24 for more detail.

E X E R C I S E

1. Explain, State, Mention or Discuss :

1. . Important points to be considered at drawing stage of a factory building.
2. Various dimensions regarding roof height, sanitary blocks, ventilation, ambulance room, canteen etc. under the Gujarat Factories Rules, 1963.
3. Dangerous operations vis-a-vis design of a factory building.
4. General guidelines (criteria) for siting of an industrial plant.
5. What are separation distances? Give the examples.
6. Factors to be considered for good planning and design of a factory.
7. General considerations for lay out and planning of a workplace/work station.
8. Safety factors for plant layout. OR Factors for process design.
9. Design aspects of floors, platforms and catwalks OR those of rail, road and footpaths. 10.
10. Ergonomic factors for layout and design of a factory building.
11. Difference between standard, code, regulation, specification and practice.
12. Advantages of good plant layout and machinery with reference to safety.

2. Write Short Notes on.

1. Indian heritage of building and construction.
2. Old Bhartiya' schools or branches of Engineering.
3. Statutory provisions for lighting ventilation, temperature and exhaust for a factory building.

4. National Building Code.
5. Siting criteria for deciding location of a factory.
6. Government guidelines for siting an industry.
7. Points to be considered by safety and layout engineer for layout of a factory.
8. Travel chart.
9. Items of good planning OR General principles for workplace design.
10. Location of electrical equipment in a factory
11. Improving safety and productivity through workplace design.
12. Factors of ergonomic design of a plant.
13. Benefits of standardization.
14. Types of plant layout.
15. Meteorological aspects.

3. Comment on following whether it is true or not and why?

1. Ancient Bharat was much advanced in architecture.
2. Environmental guidelines (e.g. rule 5 of E(P) Rules) are not useful to decide location of a hazardous factory.
3. Planning of a factory is dependent on size of land only, no other factors are important.
4. Safety and productivity cannot be improved by layout or design of a plant.
5. Environmental factors should be considered while planning for a factory.

Reference and Recommended Readings

1. References mentioned in Part-1 of this Chapter for Indian heritage.
2. The Factories Act 1948 and the Gujarat Factories Rules 1963.
3. Various Indian Standards mentioned in Part-3 and elsewhere in this Chapter.
4. Accident Prevention Manual for Industrial ' Operations, National Safety Council, Chicago, USA.

CHAPTER – 8

Good Housekeeping

THEME

1 MEANING OF HOUSEKEEPING:

Industrial housekeeping is generally classified as good or bad (poor) housekeeping. For the purpose of evaluation, ranking or marking, it is further classified as excellent, good, average, below average and poor or bad housekeeping.

The concept of good housekeeping is emerged from the results of bad housekeeping, which is the direct cause of many accidents. Poorly maintained plants and equipment, improperly stored materials, .tools and tackles, irregular or inadequate plant inspection,, unsafe environment and persons not conscious of all these are a potential cause of many accidents. Accident statistics explained in Chapter-5 and also in subsequent Part 4.1 reveals this fact In Part 12 of Chapter-5, in conclusion of the statistical tables, Some causes are highlighted to pay more attention. Majority of these causes viz. Stepping over or striking against objects, handling goods or articles, use of hand tools, falling on floor or in pit etc., hot or corrosive substances are because of poor or bad housekeeping. These causes of accidents 'can be removed by good housekeeping. This indicates the basic need of good housekeeping.

The term Good Housekeeping is sometimes loosely understood as simple floor cleaning or broom stick operation. But it is not so. It has a wider Cleaning including up-keeping of all industrial activities in orderly manner to minimise the accidents due to improper planning, placement, arrangement, .handling etc., everywhere in the industrial premises. In short it can be explained as a place for everything and everything in its proper place. It pays attention on removing all unsafe conditions in the plant and thereby increasing safety and productivity.

Housekeeping is not just a need-based cleaning. It is more than that. In addition to regular daily cleanliness, it includes orderly arrangement of tools, equipment, materials and process flow. It is an integral part of industrial activity that reduces accidents, increases cleanliness, attractiveness and comfort, production and improves employee's morale and public relations.

2 STATUTORY PROVISIONS

Sections II to 20 on health and 42 to 50 on welfare under the Factories Act 1948 and the respective rules 16 to 53, and 69 to 83B under the Gujarat Factories Rules 1963 must be referred for detailed provisions directly or indirectly concerning good housekeeping.

For cleanliness, a factory is required to keep clean and free from effluvia from any drain, privy, or other nuisance. Accumulation of dirt and refuse shall be removed daily by sweeping or any other effective method from the floors and benches of workrooms and from staircases and passages, and disposed of in a suitable manner. The floor is to be cleaned at least weekly by washing, disinfectant or effective method. Effective drainage, painting, white washing, varnishing etc., are also prescribed. Their report is to be maintained in Form No. 7. Provisions for disposal of wastes, effluents, dust and fume, adequate ventilation, lighting, workspace, drinking water, latrines, urinals, spittoons and facilities for washing, storing and drying clothing, for sitting, first-aid, canteen, shelters, restrooms, lunch-rooms and creches are also prescribed which should be checked during housekeeping inspection.

3 INDIAN STANDARDS

Some IS are : Air, clean, equipment, data sheet 12357, Air quality measurement, guide for units 9620, Air receivers for compressed air installation 7938, Air pollution control - glossary 4167,. Limits for 9005, measurement 5182, Air hose rubber - heavy duty 3557, light duty 9120, Air ducts, metal 655, Air compressor, mobile 6430, Vacuum pump - 6849, for vapour 8243, Vacuum pipe lines 8262, 9705, Vacuum producer 10678, Vacuum technology 4110, 8245, Vacuum filters 5675, 6034, Clean air equipment 12357, Cleaner - for foundry use 5841, 6443, Cleaning solution, porcelain 7983.

4 HOUSEKEEPING AND SAFETY:

Statistics of accidents suggest the items of bad or poor housekeeping and from them we infer the methods to improve housekeeping. Therefore they are considered first.

4.1 Typical Accidents due to Bad (poor) Housekeeping :

Statistics : See Table 5.8 in Chapter-5 for injuries in India in 1990 & 1991. Causation No. 10 to 15 give accidents due to (a) Hand tools (b) Falling bodies (c) Persons falling (d) Stepping on or striking against object (e) Handling goods/ articles and (f) Others. Thus total 84386 out of total 128099 (in 1990) and 42079 out of 60582 (in 1991) **clearly indicate that more than 65.87% and 69.45% accidents in India were due to the causes of bad housekeeping.**

See in Table 5.22 of Chapter-5 for industry and cause wise accidents in Gujarat in 1994. Considering Causation No. 123 to 131, in the last row of total, the accidents figures are as follows :

No.	Causes	Total Accidents
1	Others in machinery not moved by mechanical power.	511
2	Use of hand tools.	710
3	Struck by falling bodies.	980

4	Persons falling from height.	506
5	Persons falling on the flat.	474
6.	Persons falling into pits, excavation etc.	338
7.	Stepping on or striking against objects.	1472
8.	Handling goods or articles.	949
9.	Others.	3342
	Total	**98282**

Comparing with the total of all accidents 15683 this gives 59.18%. This clearly indicates that about 60% accidents in Gujarat (in 1994) were due to the causes of bad housekeeping.

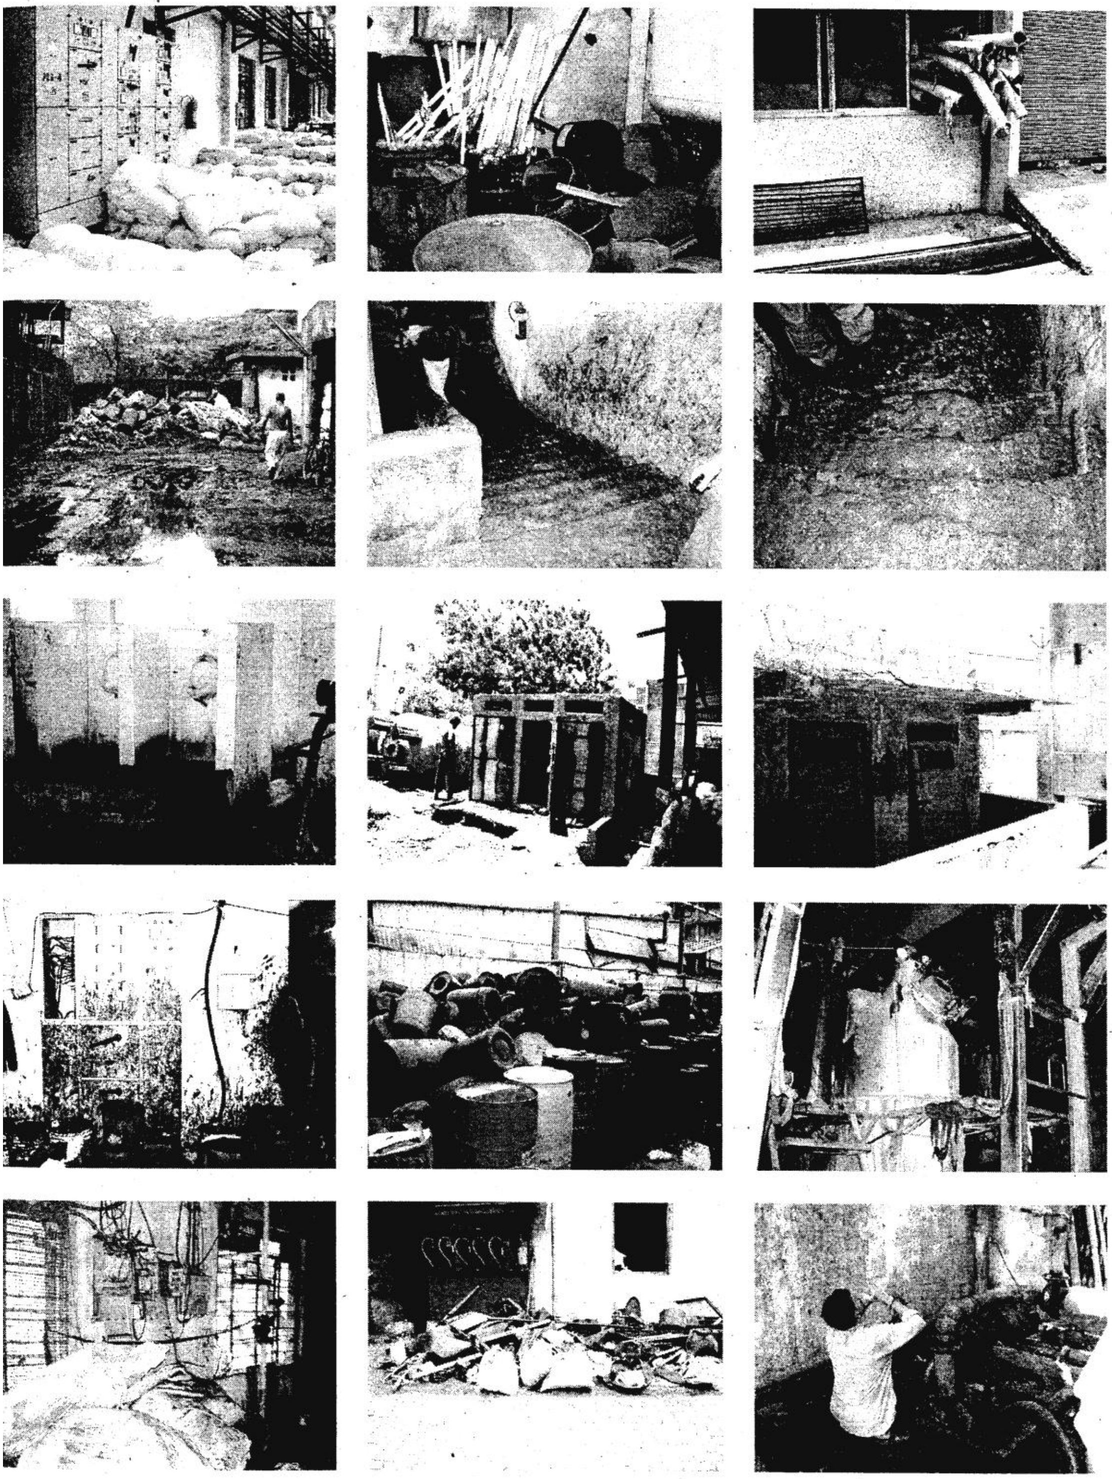
The Causes of bad housekeeping : These are well evident from above tables. The causes contributing the maximum accidents are :

1. Stepping on or striking against objects.
2. Handling goods or articles.
3. Struck by falling bodies.
4. Persons falling from height.
5. Persons slipping on the floor.
6. Use of hand tools, and
7. Others or miscellaneous.

The details or sub causes can be had from the actual accident reports. But some are as under :

Accidents due to poor or bad housekeeping i.e. their causes are : Striking against or falling over machine parts, materials or other obstructions left lying in passageways, cuts from objects left protruding from benches and especially on construction sites, punctures by nails protruding from objects or lying anywhere, falls on floor left slippery, greasy or damp, badly stacked materials, fires due to accumulation of combustible waste or leakage of flammable materials, cabinet drawers left open, dangerous dust or chemicals on floors and not cleaning them quickly,, congested aisles, no toe-guards or hand rails, overloaded waste containers, broken lockers and washrooms, dirty and unsafe walls, ceilings and windows, lint and dust on bearings of machines, tools left on machines or walkways, poor lighting, unsafe handling of chemicals; spillage of oil, grease, acid etc. on floors, pipes of air, water, steam and oil not properly maintained, no marking of safety and traffic signs, signals, loose or unsafe wiring etc. These should be the targets of planning for good housekeeping.

4.2 Indicators of Bad Housekeeping :



It is essential to know the items of poor or bad housekeeping so that they can be recognised, detected and removed. See Fig. 8.1. Such indicators of poor housekeeping are many and a list may become long. Some main indicators are listed below :

1. **Objects & Materials on Floor :** Excessive material, waste, debris, tools lying anywhere, congested aisles, walkways and workplace, spillage of oil, grease, acid etc., dropped or thrown down materials and disorderly piled material as obstruction.

2. **Poor Storage Practices :** Unsafe store design and unsafe piling i.e. too high or improper piling, overloaded waste bins, storing in aisles or obstructing doors, passage ways, storage of excessive material in work room.

3. **Equipment out of Place :** Wrongly parked vehicles, trucks, trolleys and wrongly placed tools, equipment, material, ladder, wire ropes etc. where they should not be.

4. **Dirty walls, windows, ceilings, floors etc. :** Dirty walls, windows, ceilings, floors, lighting fixtures, lint and dust on bearings or moving parts, open locker/drawer, slippy or dirty washrooms, latrines, urinals, canteens and workplaces.

5. **Poor waste disposal system :** Failure to provide receptacles or containers for waste and scrape, overflowing pans, dripping containers and unsafe handling of cutting oils etc., inadequate or leaking exhaust system, scrubber, treatment plant etc., emission of gas, fumes, vapours, accumulation of dust and no provision for cleaning device.

6. **Fire Hazards :** Accumulation of rubbish, oil, oil soaked rags or cotton waste, paper and packing material, substances causing spontaneous ignition e.g. dusts, oils, solvents, fertilisers, sugar, leather scraps, jute, hemp, hay etc., uninsulated, hot piping, hot bearings, sparks, welding-cutting in flammable area or unsafe manner.

7. **Chemical Hazards :** Nowadays chemical factories are increasing and workplace pollution due to chemical exposure is also increasing. This spoils the atmosphere and housekeeping. Splashes, leakage, dripping and escape of chemicals pose danger to health and safety and result in bad housekeeping. Acids, alkalis, solvents, pesticides and many dangerous chemicals change the colour and status of a factory. For details see Chapter-18 &19.

8. **Others :** Poor lighting, dark colours, poor ventilation, noise and vibration, broken tools, ladders, stools etc., open or loose electric wiring, no hand railing, no toe guard, no machine guarding, no fencing on pits, platforms and floor openings, drawers left open etc. -

From above discussion keys to good housekeeping are inferred as under - :

1. Cleanliness of floors, buildings & equipment.
2. Proper and speedy disposal of scrap, waste and surplus materials.
3. Keeping each object in its designated place and returning after work.
4. Sufficient work' areas, exits, walkways, aisles etc.
5. Orderly arrangement of material, process, machine, tools and equipment.
6. Good lighting, colour and ventilation.

4.3 Benefits of Good Housekeeping:

If the need, benefits, usefulness, results, advantages or effects of good housekeeping are known or explained in the beginning, it helps to provide zeal to maintain it. Therefore they are explained below. Good housekeeping increases safety and productivity as under:

1. It is an essential routine support to industrial safety and health.

2. A large number and wide range of accidents due to bad housekeeping can be eliminated by good housekeeping.

3. It aids to good maintenance and working as complementary to it and increase overall safety and productivity.

4. Clean, hygienic and safe plant environment increases attractiveness and morals of the employees.

5. Machines, tools and equipment work better in clean condition and boost up the workmanship.

6. If tools are placed in easy to find manner, job; run smoothly and give good results.

7. Clean and well maintained floors, stairs walkways, doors, windows, lifts, latrines urinals, washing facilities, furniture, records dresses, first-aid and protective equipment and proper layout of materials, tools and process flow certainly avoid many accidents.

8. Constant monitoring and control of hazardous chemicals, their processes and emission; minimise many hazards.

9. Much floor space or area is utilised because o proper access to machines and equipment for cleaning and maintenance purpose.

10. The fine and sophisticated instruments equipment and personal protective equipment give better results when kept in good and deal condition and checked regularly.

11. Accidents due to stepping on or striking against objects or fall of persons and objects, stumbling tripping, bumping, body caught between object etc. are well controlled.

12. Time spent in locating tools and appliances and wastage of time is controlled resulting in increase of efficiency.

13. Damage to person and property likely to occur due to disorder is reduced resulting in loss control.

14. Conservation of materials/property/energy results due to less scrap and spoilage and improves better capacity utilisation.

15. Loss due to misplacement of costly items would be reduced due to proper placement and order.

16. Losses due to out break of fires could be controlled to a great extent by proper housekeeping. Minimisation of losses on this account alone justifies the effort.

17. Values of materials and machines do not get reduced when they are properly maintained.

18. Overall life and utility of plant, building and equipment are increased due to good housekeeping.

19. Majority of small fires result from and spread by poor housekeeping conditions. Sources of ignition due to oily cotton waste, solvent spillage, oil dripping, friction, sparks, flames, smoking etc. can be prevented by good maintenance and housekeeping. See Part 6.5.

20. A clean and well maintained plant can be operated at a lesser cost.

21. Production increases due to reduced obstacles and wastage of time and speedy availability of material, equipment, tools etc.

22. Repair and maintenance work become easy due to easy access and clean space availability.

23. Aisle traffic becomes smoother and speedy. Truck/trolley collisions become less.

24. Employee moral is boost up due to orderly things, neatness and cleanliness, sufficient space to work, good lighting, colour and ventilation and mostly due to reduced possibilities of accidents and injuries.

25. Outside visitors, market people. Government authorities, local community and the top management are attracted and overall image of ' the company rises up.

Some examples of good housekeeping are shown in Fig. 8-2. .

5 METHODS OF GOOD HOUSEKEEPING:

After knowing the benefits of good housekeeping ' as above, the methods of good housekeeping are to be devised. Such methods are many. A few are given below:

5.1 General Considerations :

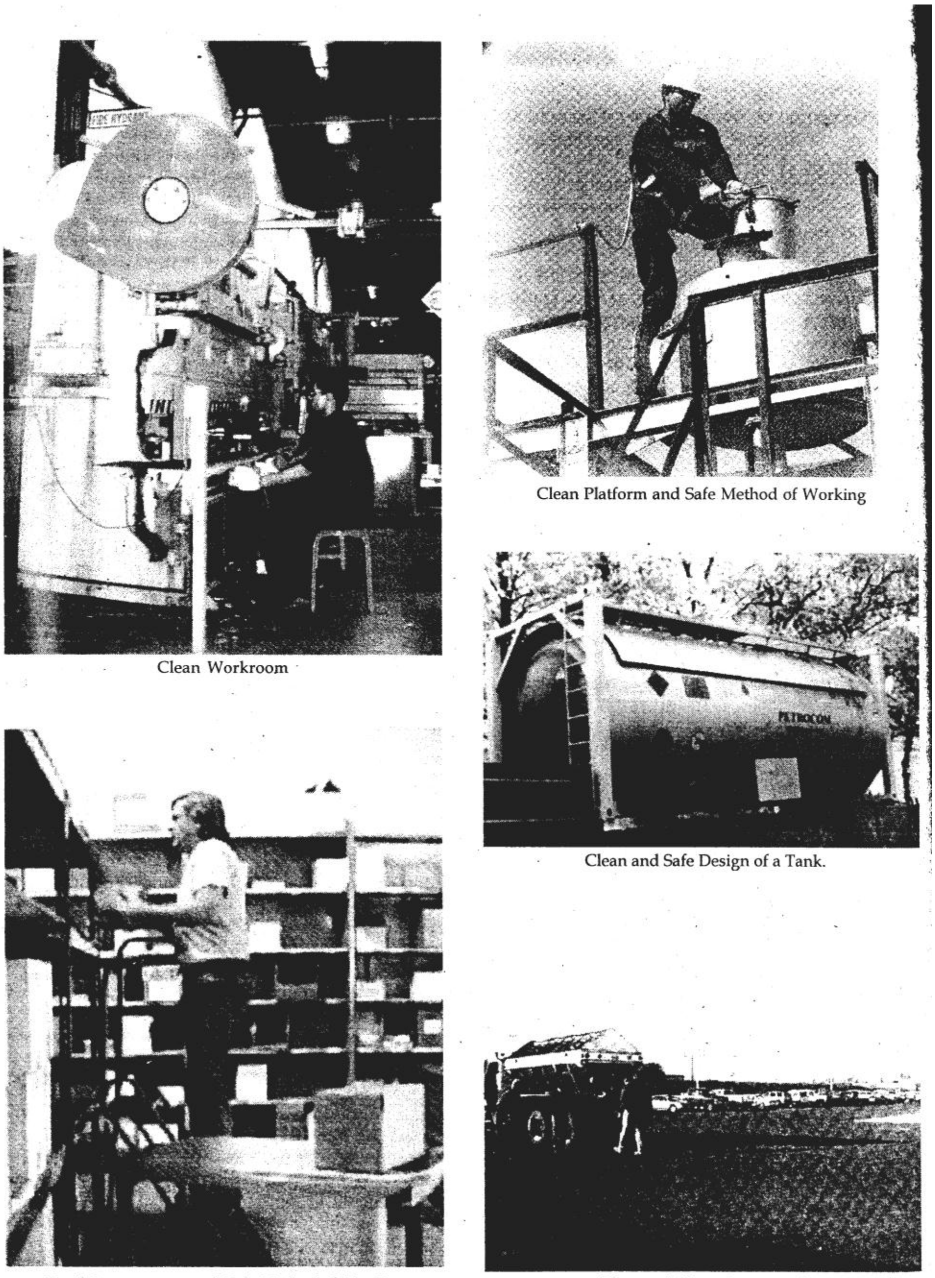
The 25 items listed in Part 4.3 suggest general considerations or essentials for good housekeeping in a factory. In short, they should include proper placement and use of hand tools, materials, equipment, clear and unobstructed workplaces, aisles stairs etc., speedy disposal of waste, scrap, splashes and obstructions, safe means of handling goods or articles, fenced platforms, floor-openings and wall openings to prevent fall accidents, removal of possibilities of falling bodies, provision of sufficient containers for waste collection, avoidance or fencing of sharp edges, corners etc., safe and efficient cleaning methods, good lighting, colour and ventilation, proper marking and identification, protective equipment to cleaners and maintenance men, special areas for storage of raw materials, finished product, tools and accessories, racks for hand tools or implements above work-benches, under bench drawer for storage of small personal possessions, devices on machines to prevent deposit of oil, water etc., cleanliness of surrounding floors, drainage, channels etc, special cleaning gangs with necessary cleaning materials and equipment, daily and weekly cleaning schedules, regular arrangements for removal of waste and emptying of waste containers, prevention of debris and clutter under benches and machine parts and special precautions depending upon the nature of industry.

5.2 Disposal of Scrap and Trade Wastes :

This is the major part of good housekeeping. Estimation of probable wastes in advance and planning for suitable means of their collection and disposal in the most economical and efficient way is desirable. Separate sweeping service, sweepers with equipment, waste and scrap receptacles with cover, overflow pans, chip screens, chip catchers, chutes, exhaust and dust collection systems, drain for liquid splash, vacuum cleaners, waste containers, methods of their transport and disposal, schedules of daily, weekly and special cleaning need attention. Such general service is not expected to pick up scrap, spoiled work, refuse, processed parts or tools. The plant workers are responsible for keeping such items off the floor. The supervisor/foreman is responsible for orderliness and cleanliness of his area. Instructions regarding hazard of cleaning up in Part 6.4 should be followed.

Hazardous waste should be disposed of with care. Fire hazards of combustible waste should be prevented. Chemical wastes should be rendered harmless before being disposed or dumped. Strong acids should be neutralised and not poured in open. Poisonous materials, explosives, radioactive waste requires special procedures for safe disposal. The workers should be properly trained for safe disposal.

See Chapter-18 for pollution hazards and control, and Tables 16 & 18 of Chapter-32.



Clean Workroom

Clean Platform and Safe Method of Working

Clean and Safe Design of a Tank.

Good Arrangement and Safe Method of Working

Neat and Clean Compound

Fig. 8.2 Examples of Good Houskeeping

5.3 Prevention of Spillage

Oil, coolant, water and chemical splashes on floors are routine phenomena in industries. If they are not quickly and properly cleaned of, they cause slips falls, burns etc. If the chemical is flammable, explosive, reactive or toxic, additional danger is added. The basic effort should start from the design of appropriate floor viz. acid proof lining, rubber lining etc., drainage system for flow collection, covering on gutters, splash guards as on jigger machines (for dyeing textile), oil or coolant screens and collection trays, drip pans to collect drippage from leaky valve, line etc. Damage to floors or such devices should be repaired immediately. Workers should be trained to remove such spillage as early as possible. Appropriate neutraliser (caustic, lime, soda, sand etc) and absorber should be used.

5.4 Marking Aisles and other Locations:

The aisles, gangways, catways, internal roads and passages, stairs, ramps and working platforms also cause accidents due to improper marking, unsafe condition and frequency of persons passing on them. Therefore they must be properly marked, equipped with necessary handrails, footholds, fencing, lighting etc., and kept clean, dry and unobstructed.

Similar marking and up-keeping of other locations such as loading-unloading or receiving-dispatch points, parking area, store area, electrical switch yard, tool room, rest-room, lunch-room, sanitary block, washing centre, drinking water centre, first-aid centre, assembly points, emergency equipment points, fire protection points, environment monitoring points, effluent points, scrubbers, dust bins, waste collection centres, dumping yard, scrap yard, storage tanks etc., also necessary for good housekeeping.

Truck, trolley, cart and moving equipment should not be left on the way to cause obstruction or harm. Aisle width should be sufficient to contain traffic. Its portion for pedestrian traffic should be distinctively marked. Bright coloured lines (e.g. zebra strips) can be used for pedestrian crossing. Yellow strip should be marked on the edge of level difference. Mirrors should be placed to judge or see the man or material approaching from the other side not otherwise visible.

Sufficient storage space should be designed and provided to contain full inventory. Design of chemical stores needs much attention. Orderly locations, placements and marking help much for better housekeeping.

5.5 Tool Housekeeping:

Disorderly placed tools or absence of holding device is a common phenomenon. Orderly arrangement of tools in crib (rack or box) or in a tool room and regular checking of tool condition and necessary repairing are most essential. Necessary tool box, pens, holders, racks, shelf etc. should be provided with the machine and also in the tool room.

A fixed tool holder (tray) with machine or a movable trolley holding a set of tools, jigs, parts etc. should be provided.

Tools placed at their proper place do not waste time in searching them. The workers and supervisors should insist for such habit.

5.6 Use of Colour as an Aid :

The subject of colour is separately dealt with lighting in the next Chapter. It is important to note here that proper colour selection for walls, ceiling, passageways, machines, piping, railings, fencing, guards, boundaries, fire equipment, lifting machines, warning signs, danger zones etc., play vital role in improving housekeeping and safety. Statutory or IS for colour-code, if any, should be followed, otherwise the selection should be based on the best effect and necessary contrast.

See Part 7 & 8 of Chapter-9.

5.7 Cleaning Methods :

Normally employed cleaning methods are cleaning by broom or brushes, vacuum cleaning, washing by water or steam, air-jet cleaning, super-sucker to suck spillage, blockade or choking etc.

Broomstick cleaning's useful for a limited area and where no much dust is accumulated. Air-jet cleaning is also not desirable in open workplace, though it is effectively useful to clean inner sides of any vessel, pipe, tube, equipment etc. But while doing so, air-pressure should be regulated (controlled) dust masks must be worn and proper dust collector should be provided.

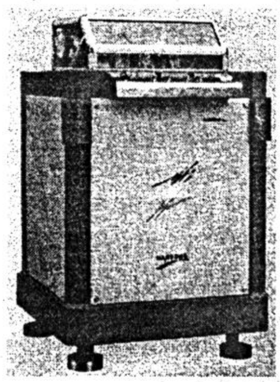
Brushes are useful to clean sticky material. Wire brushes are employed to clean hard and metal surfaces or deposits. Soap or detergent powder may be used with water.

The best cleaning method is by vacuum cleaning because it does not push or cause to fly dirt or dust here and there but pulls inside the dust chamber which can be emptied at a desired place. This method has the least health hazard as it does not allow dirt or dust in atmosphere. It can suck dust from air also. Vacuum cleaners are available of different sizes and capacities. They may be portable or fixed for particular location, machine or system.

Local exhaust ventilation (LEV) is an improved design of vacuum cleaning device and effective engineering control to collect dust or waste from near the source of generation. Its application in industry is very wide and instead of cleaning device it is considered as an integral part (safety device) of .the machine or equipment to which it is attached. Carding machine (textile), buffing and polishing machine, grinding wheels and many dust or gas generating processes (e.g. acid cleaning) are provided with such local exhaust ventilation or dust collectors. See Table 18 in Chapter-32 for guide to select dust collectors.

Portable cleaning device

In chemical and metal industry, special cleaning agents - HGI, H,O,, HP etc. - decreasing agents and organic solvents are used .to clean metal surfaces and piping. Purging by air or nitrogen is also utilised to clean vessel, equipment, pipeline etc.



Trolly mounted portable cleaning device is available to clean floors, walls, vehicles, storage vessels, machine tools, construction machinery, factory shade etc. High pressure jets are used to clean effectively. It removes dust, scale, oil, grease, rust etc from the surfaces. Plain water or water mixed cleaning agent can be used.

Parts washer is also available to clean small parts of labouratories, auto mobiles, metal, plastic and glass, general machinary, service stations etc. Cleaning is done in enclosed chamber. It removes oil, grease, rust, dirt, paint, scale, scrap, burrs etc. Washing pressure is kg/cm2.

6 MANAGEMENT OF GOOD HOUSEKEEPING

Good housekeeping is not possible without management policy, planning, efforts, responsibility, follow up and overall co-operation of all plant people. -This is explained below :

6.1 Management Policy and Responsibility :

Like Safety, health or quality policy, the top, management must establish, declare and implements housekeeping policy emphasising that

1. Dirt and disorder are always evidence of waste of materials, time, energy and effectiveness.
2. Regular cleaning of dirt and maintaining orderly things may be a tough job, but it is the management's responsibility.

3. Good housekeeping reduces accidents and increases safety, productivity and morale.
4. Working in dirt, dust and disorder increases cost and decreases workers' comfort,
5. If you can't manage to have cleanliness and order, you can't manage your department.

Management must formulate such policy, encourage supervisors to' implement it and help removing beliefs like 'That is naturally dirt/,'IP cannot be avoided', 'How many times to clean it ?'

If top management, will accept this policy and responsibility, others will follow it. Housekeeping programmes must be 'planned, promoted patiently, regularly and carefully.

6.1.1 Planning and Follow up :

Merely wishing good housekeeping is not sufficient. Certain policy must be established and followed. Aids and equipment necessary for good housekeeping must be purchased. The management must understand the results of bad housekeeping and must accept responsibility for good housekeeping

Planning and follow-up should include -

1. Deciding policy and technique for good house keeping.
2. Proper layout of work area.
3. Marking of aisles, ways and storage areas.
4. Cabinets and holders for tools and equipment.
5. Storage arrangements for materials.
6. Containers for materials in process.
7. Efficient sequence of operations to avoid bottlenecks.
8. Anticipation of waste, scrap, dust, spillage, splashes etc., and inclusion of methods of their control stated in Part 5.2.
9. Efficient transportation of raw material, finished:; products and refuse. Use of mechanical feeding belt conveyor etc..
10. Efficient cleaning methods including vacuum cleaners etc., and without interrupting the production schedule.
11. Necessary training of workers.

This is a sample list which may be modified according to the particular requirements of a plant.

Good housekeeping cannot be left to the unplanned activities of persons employed. It is a management technique and it should be laid out in such a way that it is easy for order and cleanliness to be observed.

A good housekeeping committee, competition, rewards and individual and group incentives for good housekeeping play an important role to increase and maintain motivation for housekeeping.

6.1.2 Overall Co-operation :

After setting up of policy and programme for good housekeeping and division of responsibility for implementation and compliance up to the floor level, it becomes necessary that all plant people must wholeheartedly co-operate for the success and achievement of good housekeeping in every corner and at all times.

Supervision and cleaning arrangements for working areas and sanitary facilities are essential. It is necessary to maintain interest of all plant people for such co-operation. Motivation and competition bind the co-operation. Co-operation of safety engineer/officer, supervisors and workers in their respective areas is most important for overall efforts of good housekeeping. They are explained below in brief.

6.1.3 Housekeeping Contests :

To stimulate the interest by an element of competition, many times housekeeping contests are arranged between different departments or groups of a factory or between different factories on district or state level where organisations like National or State Safety Councils take interest.

Committees are formed to inspect participating departments. Representatives from different departments should be co-opted by the safety department.

Inspection may be limited to the period of contest only or it can be made regular by making it monthly, bi-monthly or quarterly. The visit should be unannounced so that real picture can be seen and regularity in housekeeping may be developed.

An award, prize or incentive may be given to the winning department (to its leader or to all employees of that department). Small gifts of attractive or useful nature may also be given. Such awards should be given m a function of all employees and by the hands of the top executive. Supervisors of the winning department should be specially complemented. Their encouragement is most important to get the work done.

6.1.4 Employees Assignment:

It is the management's responsibility to assign sufficient employees to carry out routine daily housekeeping job. Mostly such work is given on contract and company employees believe that housekeeping is not their job. However where this job is assigned to company employees, the picture is not good at some places. Because of unionism, company employees are less duty-conscious and not that much regular as the contract workers. Such tendency is diverting more -and more jobs to contract workers. Housekeeping, gardening, security, transport, canteen and other welfare activities are such jobs.

Depending on number of latrines, urinals, bathrooms, washing facilities, canteen, rest room, lunch room, medical centre and size of work areas, compounds, roads, godowns etc., sufficient number of employees should be allotted for housekeeping work. If more than one shift are running, appropriate staff in each shift is necessary.

If sufficient manpower is not assigned looking to the area and hours of work, good housekeeping cannot be achieved. Economy or shortage in manpower will result in bad housekeeping. But because of increasing cost of manpower, compulsion of reduction in cost of production in competitive market and availability of cleaning machine replacing manpower, proper balance has to be maintained in assigning employees for housekeeping.

However, it should be borne in mind that dirtiness and bad housekeeping create health and safety problems and may increase medical expenses, absenteeism and HR problems. Therefore employee assignment for housekeeping job needs careful consideration and due weightage.

Instead of solely depending on or waiting for employees for housekeeping job, if each company employee feels his own duty to clean and maintain own workplace, own machine and own table, it will be more meaningful and useful. 'Housekeeping is everybody's job' should be the concept. 'Work is worship' is not a slogan, it is to be practised.

6.2 Safety Officer's Role :

A safety officer has to play an important role by

1. Suggesting the best housekeeping policy, procedure and equipment to the top management.
2. Co-operating in finalising the policy and planning including preplanning, space requirements and facility requirements for good housekeeping.
3. Implementing the policy, procedure and programmes through supervisors, workers and all concerned throughout the plant.
4. Advising and assisting all plant people for their co-operation in good housekeeping efforts.
5. Solving the problems by appropriate design, layout, planning and purchasing equipment for good housekeeping.
6. Arranging supervision, competition, award and incentive schemes to improve housekeeping and maintain interest.
7. Designing and arranging regular and special inspections, checklists, rating forms and records for good housekeeping.
8. Paying more attention on all points mentioned in other parts of this Chapter and particularly on (a) Clean premises, machines, equipment and orderly layout (b) Clean and hygienic sanitary facilities, bathrooms, cloak-rooms, mess rooms etc. (c) Storage places for raw materials properly classified (d) Cabinets and holders for tools and portable equipment (e) Containers for materials in process and products (f) Prompt removal of dirt, dust, refuse, splashes, wastes and unwanted 'materials (g) Careful training of workers and (h) Maintenance of plant 'including lighting, painting and motivation for good housekeeping.

6.3 Supervisor's Role :

For good housekeeping the interest and cooperation of the supervisory group is more important as it is the more responsible group and more close to the working conditions and workers. All supervisors must provide initiative and leadership for daily attention of the workers on cleanliness and orderliness of workplace, machine, equipment, tools, materials etc. in their control.

They have to carry out the management policy, programme and maintenance of good housekeeping in their areas. They should take part in competition of housekeeping and try to win awards for that. They can contribute much to boost up workers' morale, attitude and enthusiasm towards their day to day checking and. efforts for good housekeeping. They have to obtain co-operation from all workers for their success. If any award for rating standards are prescribed for their superior performance, they should explain the workers how to achieve them. They must pay constant attention on all items of removing bad housekeeping and maintaining good housekeeping.

6.4 Workers' Role:

No success is possible without workers' efforts and co-operation for any safety or housekeeping programme. This should be taught to them from their initial training. Creating and maintaining their interest is most important. It is the management's skill and workers' wish to do it. They have to implement the policy and checklist given to them for good housekeeping. A list of items of daily and periodical checking should be prepared, displayed and followed up accordingly. It should contain the items given in

Part 4.3, 6 & 7 of this Chapter, but selective for their job and place requirement. To keep their own place of work, machine, equipment, tool etc., clean and in working order is in their interest. *Nobody else can keep their things so clean and in order as they keep for themselves. Daily they should spare a few moments for cleaning up.*

Hazards of cleaning up in proximity to moving machinery must be informed to workers. The workers for such work should be well aware of -

1. Risk of entanglement, use of compressed air, electric shock, chemicals, cuts from scrap metal, swarf or broken glass etc.
2. Skin affections and dermatitis due to detergents, oils and cleaning materials.
3. Need to wear personal protective equipment for protection from striking by objects, stepping over sharp edges, handling such material or facing dust, fumes, gases, splashes etc.
4. Need of washing, cleaning, first-aid treatment and vacuum cleaning when required. To keep top cover and bottom (drain) valve open while cleaning any tank from the top.

6.5 Role of Maintenance:

The term **maintenance** maybe mixed with the term good housekeeping and therefore their difference should be understood.

Maintenance covers the work done to keep building, plant, equipment and machinery in safe and efficient working order and in good repair, the upkeep of all sanitary and welfare facilities and the regular painting and cleaning of walls, ceilings and fixtures.

Good Housekeeping includes day-to-day cleanliness, tidiness and good order in all parts of undertaking. Good housekeeping is not possible without good maintenance and vice versa. Thus both are complementary.

Preventive maintenance is a scheduled or regular periodical maintenance of plant and machinery. Its purpose is to prevent sudden or accidental failure, stoppage or breakdown of plant and machinery. Without waiting for breakdown or failure, periodical oiling, greasing, tuning, changing of parts, testing and examining keep the machinery in efficient working condition, smooth running without excessive noise and vibration, leakage etc and it helps to maintain good housekeeping. Sometime 'shutdown' is planned for such preventive maintenance.

Productive maintenance is for the purpose of improvement in production. If speed or output is decreased, noise, vibration, out running, reject, breakage, leakage etc. may increase, then such maintenance is carried out to remove these losses. Even without such losses or disorder, modification is carried out to boost up or increase the production rate or to achieve desired quality or quantity of products.

Breakdown or corrective maintenance is compulsorily required when plant or machinery stops due to breakdown, sudden failure, stoppage, accident or leakage etc. Then without urgent repair, restarting is not possible, otherwise it adversely affects housekeeping.

See Part 8.5 of Chapter-4 and Part 15.8 of Chapter-18 also.

Thus role of any type of maintenance is to improve safety, productivity and housekeeping.

7 JAPANESE CONCEPT OF 'FIVES'

A Japanese concept for good housekeeping states ‘Five S’ as under -

1. **Seiri** : This means segregation. Dirt, dust, rubbish and all unwanted wastes or material should be collected and segregated first.

2. **Seiton i.e. arrangement.** There should be effective arrangement of safe disposal of segregated wastes. This also includes preventive ' arrangement such as local exhaust ventilation, dust collectors, vacuum cleaners, guards, covers and devices to reduce noise, vibration, leakage, spillage etc.

3. **Sciso or cleaning.** Main activity of good housekeeping is cleaning. It includes cleaning of floors, walls, ceiling, sanitary and welfare facilities, parts of plant and machinery, PPE and other equipment, tools, lighting fixtures, lamps, tubes etc.

4. **Seiketsu i.e. maintenance** of standard. This suggests compliance of statutory provisions and national or international standards for safety, quality, cleanliness and environment. Maintenance should also include all activities mentioned in Part - 6.5.

   For example, maintenance of standard mentioned in Schedule 2 of the Factories Act and Form 7 and 37, GFR, indicates status of housekeeping.

   For statutory provisions see Chapter 27 and 28.

5. **Shitsuke or Discipline** - This indicates duty of everybody to follow rules, regulations, instructions, notices, orders, appeal etc for maintaining good housekeeping and safety.

   Notices to spit in spittoons only, not to throw rubbish anywhere, not to smoke in flammable areas, not to run machine at over speed, not to open guard or safety devices without authority, not to waste water, power, oil etc, to follow traffic and safety rules, to wear ear protection in high noise area and other PPE for specific woik,to use proper tools and equipment etc should be strictly followed as discipline. Motivation is required for self discipline. For maintenance of good housekeeping discipline plays a vital role.

8 INSPECTION AND CHECKLISTS

8.1 Inspection Rating :

Purpose of housekeeping inspection is to detect the items or causes of bad housekeeping to remove them. Such inspection may be by an individual such as supervisor, inspector, plant in-charge, safety officer, superintendent or by a housekeeping committee, safety committee or team consisting some of them as per requirement. Instead of inspecting own department it is advisable to inspect other's department to avoid any favour or bias. Monthly inspection is sufficient. It may be weekly also.

For a systematic inspection, a checklist should be prepared covering our own plant details and specific requirements. Condition ratings should also be fixed for easy marking or evaluation. A specimen checklist with score (marks) 0 to 10 is described below:

A. **Excellent Housekeeping** (Score 10.0 to 8.1) General appearance very neat and tidy. Gangways very clean. Pieces of cotton waste, papers etc., not seen on the shop floor. Materials stored in very orderly manner. Portable machines, hand tools, equipment etc., kept tidily and in orderly manner. No leakage of compressed air, oil or any material. Roofs, fixtures and fittings etc., free from cobwebs.

B. **Good Housekeeping** (Score 8.0 to 6.1) General appearance clean. Gangways and shop area fairly clean. Most of the materials stored properly. Machines, equipment kept clean. No cobwebs on roofs, fixtures and fittings.

C **Average Housekeeping** (Score 6.0 to 4.1) General appearance satisfactory.. Gangways free from materials, cotton waste or pieces of papers. Cleanliness on the remaining floor area average. Machines and equipment kept reasonably clean. Roofs, fixtures and fittings not thoroughly free from cobwebs.

D. **Below Average Housekeeping** (Score 4.0 to 2.1) General appearance not satisfactory. Gangways partly blocked with materials. Few pieces of cotton waste seen on the gangways. Other shops are not clean. Machines and surroundings not clean. Cobwebs on roofs and walls, fixtures and fittings not clean.

E. **Foot Housekeeping** (Score 2.0 to 0.0) General cleanliness much below the required level. Gangways blocked with materials and pallets. Pieces of papers, cotton waste etc, seen on the floor. Machine and equipment not clean and dripping with oil and grease, etc. Materials not stacked properly.

Such items and rating may vary. They should be devised according to need.

8.2 A Model Checklist :

Housekeeping checklists are many and they may differ for details. Plant in-charge should design its own checklist best suitable to it. Such checklist must cover all statutory points. A sample checklist is given below. Write replies and remedies against each item. -

1. **Plant Layout :** (1) Are Size, shape, location, construction and layout of building, machinery and other facilities permit the most efficient and orderly utilisation of men, materials and machinery ? (2) No doubt this aspect should be considered at the design stage, still some improvement can be expected with slight modification and adjustments in die old layouts. Is such modification necessary for good housekeeping?

2. **Storage :** (l) Are materials or items stocked too high? (2) Arc stairs, fire escape exits? Fire extinguishers obstructed? (3) Are aisles free from obstructions? (4) Are items over hanging or protruding so as to cause injuries? (5) Are bin cards and tally cards displayed for identification?

3. **Interior Arrangements :** (1) Are machines, benches, cabinets, racks so arranged as to facilitate good housekeeping? (2) Are aisleways marked? (3) Are marshalling areas so located as to encourage their use? (4) Is colour or white washing in attractive and appealing condition? (5) Are sitting facilities provided and furniture in good condition?

4. **Machinery and Equipment :** (1) Is machinery/ equipment well maintained and colour coded? (2) Is there any leakage of gases or spillage of liquids? (3) Is there any deposition of dust or other contamination on them? (4) Is moving machinery well guarded? (5) Are they causing noise or vibration ?

5. **Electrical fitting and illumination :** (1) Are cables or wiring loose or hanging? (2) Are sockets, plugs provided and cables are of standard requirement? (3) Are all areas sufficiently lighted to reveal dirt obstructions and hazardous conditions? (4) Are there burned out bulbs or sockets without bulbs or light shades hanging? (5) Is there dirt or dust on the control panel or instruments? (6) Are trenches full of rubbish? (7) Are all earthings all right?

6. **Floors, drains, pits and manholes :** (1) Are floors uneven and dirty? (2) Are drains full of waste and choked? (3) Are drams and manholes open? (4) Are floors dirty and slippery? (5) Are maintenance materials like gaskets, nuts, bolts, nails etc., scattered? (6) Is cotton waste or oily material thrown on the way? (7) Are pits and opening fully covered or guarded?

7. **Platforms and stairs :** (1) Are control valves at height provided with platforms and ladders? (2) Are platforms and staircases provided with hand railings and toe guards? (3) Are ladders provided with handrails? (4) Is ergonomic design followed ?

8. **Sanitation and ventilation :** (1) Is ventilation adequate throughout the area? (2) Is there indication of rodents and insects? (3) Are personnel eating in work areas creating in sanitary conditions? (4) Are urinals and bathrooms stinking and require white washing and disinfectant spraying and cleaning? (5) Are unnecessary odour prevalent? (6) Are proper receptacles provided for the waste?

9. **Fire extinguishing System :** (1) Are all extinguishers charged of correct type, in their proper place and readily accessible? (2) Are plant personnel trained in fire fighting?

10. **Safety and First-Aid :** (1) Are required type of safety appliances available, kept in proper places and well maintained? (2) Are first-aid boxes or eye irrigators kept at proper places and well maintained? (3) Are persons trained in the use of first-aid appliances and first-aid practices?

11. **Yard Areas :** (1) Is material properly segregated and kept in earmarked areas? (2) Is proper dunnage and pallets provided wherever required? (3) Are identification boards displayed on each material? (4) Are areas free from unwanted growth of grass or shrubs?

12. **Display and Identification :** (1) Are process flow sheets and circuit diagrams displayed at appropriate places? (2) Are lubrication and maintenance schedules displayed? (3) Are safety, first-aid and hazard posters and charts displayed? (4) Are equipment identified properly?

Another checklist for working conditions and productivity in small and medium-sized enterprises, suggested by ILO is given as Table-6 in Chapter-32.

9 HOUSEKEEPING OF SPECIFIC INDUSTRIES

Special nature of industry needs special items to be included for its housekeeping. Problems of housekeeping are not same in engineering, foundry and pharmaceutical factories. Some factories become more dusty and dark due to their processes. Chemical factories have special hazards. Therefore their specific points must be considered well in advance at the designing stage so as to facilitate easy housekeeping Rule 16 of the Gujarat Factories Rules gives a schedule of factories to which provisions of painting, white washing etc., are not applied. Blast furnaces, brick works, cement works, copper mills, gas works, iron and steel mills, stone, slate and marble works are exempted thereby. Simple washing, sweeping, brushing, dusting vacuum-cleaning etc., are required for them.

A **specimen checklist** for an engineering factory is given in Table 8.1 as a guide.

Table 8.1 : Weekly Check List for Housekeeping of an Engineering industry

Sr.	Check List	Yes or No.		Comments & Action to	Action By	Remarks

			be taken
1.	Shop/ Work Areas :	(15)	Is there leakage or accumulation of combustibles? Dykes provided surrounding tanks?
(1)	Is the floor swept properly and kept clean?	(16)	Is there any loose and hanging temporary wiring? Earthing broken?
(2)	Are the gangways & passages clearly marked and completely free of materials?	(17)	Are all instruction charts, sign boards, notice boards, etc. in position and kept up-to-date? Notices for 'no smoking", 'high noise area' etc. displayed?
(3)	Are the stairs/staircases, ladders swept properly? Is the approach clear?	(18)	Are the lavatory blocks clean & deodorised?
(4)	Are the drains kept clean and unobstructed?	(19)	Are the water coolers clean? Is there any water spillage?
(5)	Are the machines and equipment kept reasonably clean and guarded while working?"	(20)	Are fire protection appliance kept unobstructed?
(6)	Is shop free from accumulation of oil, grease, oily rags etc.?	(21)	Are the lockers & cupboards clean and kept in orderly manner?
(7)	Are the window glasses, north light' glasses and partition glasses clean?	(22)	Are first aid boxes at proper places ?
(8)	Are the roofs, walls etc., completely free from cobwebs?	(23)	Local exhausts and dust collectors properly working ?
(9)	Are lighting fixtures, fans etc., wiped and cleaned?	(24)	Lifting machines marked with SWL ?
(10)	Are tables, chairs, racks, cupboards etc., clean?	(25)	Rotating machines marked with notices of speed?
(11)	Is the shop clear from all the scrap and other unwanted materials? Is there proper location for discarding these?	**2.**	**Scrap Collection and Disposal:**
		(1)	Is die scrap and garbage collected nearly at one place regularly?
(12)	Are the raw materials stacked and stored properly and in orderly manner?	(2)	Is the disposal being done regularly/frequently as necessary?
		(3)	Is area in and around the shop/building kept free from accumulated packing, scrap & other materials?
(13)	Are there any wastage / leakage of water, electricity, fuel, steam, compressed air seen?	**3.**	**Use of Uniforms, PPE etc:**
		(1)	Do workers wear necessary uniform and PPE?
(14)	Whether lighting & ventilation is proper and clean?	(2)	Do they use proper tools and equipment ?

(To be used by the Shop Foremen / Section Heads)

Note : Please mention any other items (not included above) which require immediate attention or additional measures to be taken to improve housekeeping in your shop.

EXERCISE

1. Explain, State, Mention or Discuss :

1. Good and bad housekeeping.
2. Benefits or results of good housekeeping.
3. Statutory provisions regarding good housekeeping.

4. Indicators of poor housekeeping.
5. Various items of industrial housekeeping.
6. Various types of cleaning methods.
7. What will you include in planning and follow up for good housekeeping?
8. How are housekeeping contests helpful?
9. Safety Officer's OR Supervisor's role for good housekeeping.
10. Workers' role in plant housekeeping.
11. Three types of maintenance and their effects on housekeeping.
12. Contents of a model checklist for good housekeeping.

2. Write Short Notes on :-

1. Meaning of housekeeping.
2. Difference between housekeeping and maintenance.
3. Typical accidents due to bad housekeeping OR the Causes of poor housekeeping.
4. Disposal of scrap and trade wastes OR Location requiring marking.
5. Marking aisles and other locations OR Examples of good housekeeping.
6. Colours as an aid for good housekeeping.
7. Management's role for good housekeeping.
8. Employees' assignment for housekeeping.
9. Concept of 'five S' for housekeeping.
10. Checklist with rating for housekeeping.

3. Comment on following explaining whether it is true or not:-

1. Poor housekeeping is not the reason of accidents or injuries.
2. Good housekeeping has effect on safety and productivity.
3. Human 'factors and habits have nothing to do anything with housekeeping.
4. Orderliness is a part of housekeeping.
5. Housekeeping contests are of no use.
6. Safety Standards can be improved through good housekeeping.
7. Pre-planning helps housekeeping.
8. Safety Officer is not meant for housekeeping.
9. Maintenance has not to do anything to improve housekeeping.
10. Policy is not required for housekeeping.

1. ILO Encyclopaedia of Occupational Health and Safety, ILO, Geneva.
2. The Factories Act and Rules.
3. Safety and Good Housekeeping by NPC, New Delhi.

CHAPTER – 9

Lighting and Colour

THEME

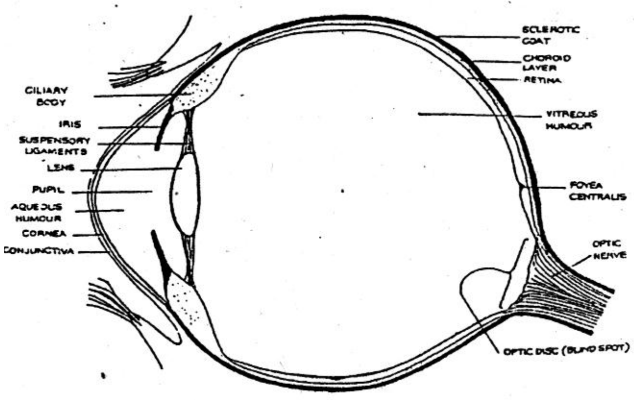
1 SIGHT AND LIGHT

Sight and Light are the supreme need of life. Without eyes, sight and vision, life is incomplete. In Part 8.2.4 of Chapter 6, a Sanskrut stanza is given explaining that a mirror is of no use to him who has no eyes. The first and foremost sense required and being utilised for human activity is sight.

The divine and powerful source of sight, light and life is the SUN whom we call 'Surya' and worship. It is the Sun only who is giving life to all of us and the whole universe, who throws ample light everywhere (if not obstructed) and gives sight to our eyes. Our artificial lighting is not at all comparable with its natural lighting, in terms of quantity, quality and cost.

The fulfilment of almost all tasks depends on proper visual perception and it is estimated that about 80% of the sensory information for any work performance is received by brain through eyes only. Ordinarily all persons put reliance on sight than on any other senses, because without sight it is difficult to understand and judge about any object or action. Thus the importance of eyes, sight, or vision must first be understood.

The human eye has visual acuity or an ability of accommodation i.e. the ability of the eye



Inner parts of human eye

to change its effective focal length to see or distinguish objects distinctly at. varying distances. Adaptation ability of an eye is its sensitivity adjustment effected after sufficient exposure to light (light-adapted) or darkness (dark-adapted). Dazzling conditions and frequent adaptation may cause visual fatigue and eye troubles conductive to accidents. Convergence means an ability to get the impression of a single object through two images on the retinas of both eyes. Depth Perception or Stereopsis is the impression of depth gained from the fact that both eyes see an object from a slightly different angle. Sudden closure of eye-lids against excessive light is the safety response. Colour vision is due to the ability of the retina to distinguish between light of different wavelengths. It is not equally sensitive to all wave lengths.

But the sight cannot do anything without light. The eye can portray to the brain only such impressions as are carried to it by light waves, and if these light waves are insufficient because of poor illumination, the effect is the defect in performance. Inadequate visual perception is a direct or indirect cause of many accidents. Visual perception depends on many factors which must be studied, to improve them. Some such factors are:

1. The eyesight of a person.
2. The quantity and quality of light on the object to be seen.
3. The size, shape, speed arid distance of the object.
4. The degree of colour contrast between the object and its background.
5. The obstructions, transparent or nontransparent, in the path of the light rays between the eye and the object.
6. Glare and shadow if any.

Thus light, colour, their quantity and quality are the important factors for any visual perception and work performance-depends on it.

2 PURPOSE AND BENEFITS OF GOOD LIGHTING

2.1 Purpose and Advantages of Good lighting:

Purpose, need, advantages or benefits of good lighting are many. There are three groups of working conditions : (1) Physical or environmental i.e. lighting, ventilation, noise, atmospheric conditions etc. (2) Relating to time i.e. hours-of work, rest pauses etc. and (3) Relating to social situation within which an individual works. The lighting influences all the three categories and is an important working condition not only in factories but at all work places. Therefore it should be effective and not poor.

The purpose of light is most important, because without light the things have no appearance, no colour, no shape and no perspective. Light and colour affect human efficiency, accident-possibility and his general well-being, morale and fatigue. Medical research has proved that a sufficient amount of light is needed for the healthy physiological functioning of human organism. Light regulates various physiological functions within the body and poor light adversely affect the health. .

Benefits of good lighting are also direct and manifold, because, it affects our sight as well as the object to be seen. It helps in two ways, by better seeing for work performance and better environment. Better seeing condition causes better discrimination, concentration, alertness and less fatigue. Better discrimination causes less spoilage and quick fault detection. Greater concentration causes better work. Less fatigue allows greater output and greater production. Better environment produces better morale,. comfort, supervision and interest. All these factors cause better ability to perceive objects and keep a clear view of all details, of better conservation of energy and material, reduced labour turnover, better housekeeping, more production with less waste of material, energy and labour, prevention of eye strain and accidents, increased accuracy, efficiency, productivity, speed of seeing and reading and improvement in health and safety of work-people. It is most useful to elderly people.

2.2 Effects of Bad or Poor Lighting:

Effects of bad lighting are direct and manifold, because, it affects our sight or visual perception. Bad light causes glare, shadows, darkness, eye strain, restricted vision, fatigue, headache, slower reaction and greater susceptibility to error and accident and lower output. Accidents during night are obvious due to bad or insufficient lighting. Therefore, need of light is basic and essentially required to work better, to avoid eye strain and to reduce accidents.

Gloomy, dirty and poorly lighted workplaces cause depression. Poor lighting causes great hardship e.g. difficulty in reading micrometer, making fine adjustment, passing a thread in needle and the like. Conversely, well lighted workplace looks delightful and encourages to work.

Poor lighting requires more time to see or distinguish object. Glare and shadows cause eye-strain resulting in more chances of accidents. Therefore to increase safety, prescribed standard of illumination is the basic (minimum) working condition. See part 4 for Standards.

2.3 Increase of Safety arid Productivity due to Good Lighting :

Good lighting includes both, day lighting and artificial lighting and they should be in the requisite proportion. The spectral composition of light and colour layout should be appropriate to gain their maximum advantages.

Good light decreases accident and increases work quality and quantity, productivity and promotes better health and morale of all work-people. In industry, therefore, it is the duty of lighting engineer to consider this basic need and to provide good seeing conditions to,, avoid accidents due to visual disorder. Planning from the design stage will help much.

Good lighting makes the worker more alert and enables him to concentrate and use better discrimination which result in less spoilage, less rejects, fast fault detection, better work and ultimately in Safety.

Numerous studies have shown a close relation between accident frequency and lighting conditions.

An old study by the National Industrial Fatigue Board (USA) indicates that work output (efficiency) decreases because of poor lighting. The change in efficiency as measured by production record and number of errors made because of change in illumination was the subject of numerous studies. Improvements in lighting increase production and decrease errors.

In one case study (Electrical Times of 14-031980), accidents decrease in three companies was 50%, 43% and 52% as an effect of improved illumination.

The Travellers' Insurance Company estimated that of 91000 accidents, 24% were due to imperfect lighting.

One 18-days study showed that the employees with the greatest deviation from the visual standards had the largest accumulation of accidents.

In one factory when illumination was increased from 50 to 200 Lux, the reduction in accident was 32%. Another reduction of. 16.5% was noticed when the walls were treated with high reflectance paint which increased the illumination level to @ 250 Lux.

In a machine tool factory with the rise from 32 to 430 Lux and machines painted to reduce brightness contrasts, the accident rate was decreased up to 50%.

In a textile mill with the prescribed illumination level, a safety award was won for its accident-free performance. This proves that good lighting increases safety.

A few examples from the samd journal are reproduced in Table 9.1 to show such effects.

Table 9.1 : Effect of Light on Work

Type of Work	Illuminance (Lux)		Performance Increase (%))	Rejects Decrease (%)
	Old	New		
Composing room (print)	100	1000	30	18
Cotton Spinning Mill	170	750	10.5	39.6
Wood MFg. Co.	300	2000	16	29
Screw Sorting	100	1000	10	22
Telephone Assembly	150	250	36	57
Tool Co.	500	2000	10	20

The results of a study made by the Research Centre for Lighting Practice, Germany, showed that the increase from 100 to 300 lux raised the productivity by 4% and from 300 to 400 lux raised further increase of 2%.

These results conclude that there are optimum Sighting conditions for each job, the intensity and nature of which can usually be determined through experimentation. A mark increase in intensity in one place may not produce results commensurate with the additional expense. The power necessary should be determined in terms of comfort for the person with normal visual actual acuity and the production records. More luminance level is required after the age of 40.

The specified result improvements (in quantity and quality) were the outcome of the combined effect of the improvement in the primary visual functions (vision acuity, contrast sensitivity, depth and colour distinction etc.) and light dependent increase in psychological and physiological activation.

Emergency lighting should be provided where power failure is frequent and no natural lighting is possible due to absence of windows etc.

3 PRINCIPLES OF ILLUMINATION

3.1 Definitions :

Light is the electromagnetic visible radiation (waves) Within the range of 380 to 760 nanometres (I nm = 10-9 m) or 7.5 x 1014 to 4.3 x 1014 hertz (Hz). The optical spectra, the luminous (electromagnetic) radiation capable of inducing visual sensation through the eye within the range of wavelengths from 10 to 340000 nm, can be divided, depending on wavelengths, into the ultra-violet region (from 10 to 380 nm), the visible region i.e. light (from 380 to 760 nm), and the infrared region (from 760 to 340000 nm). In the visible region, colours from violet (380 nm) to red (760 nm) are recognisably visible. The sensation of colour is also associated with the radiation wavelength.

Luminous radiation exerts certain influence on the nervous system, pulse rate, intensity of certain metabolic reactions and the psychological state of man. For a rational or an adequate lighting, the quantity and quality of illumination, both are essential. Some basic concepts, units and symbols are as follows :

(A) **Luminaire** is a complete lighting unit including the lamp, globe, reflector, refractor, housing and support that is integral with the housing.

(B) **Luminous (or light)** flux is the quantity of light emitted per second by a light source. It is the radiant power or luminous flux i.e. rate of propagation of radiant energy evaluated by the eye. Its unit is lumen (1m) and the symbol F.

(C) **Luminous Intensity** is the luminous flux emitted per unit of solid angle (the measure of spatial density of the light flux) in a given direction. Its unit is candela (cd) and the symbol 1 and 1 = F/w, where w is the solid angle.

(D) **Illuminance or Illumination** is the luminous flux that strikes a unit area i.e. it is the surface (E) density of the light flux distributed uniformly over the surface. Its unit is lux (lx) which is equivalent to 1 $lm/^2$ and the symbol E, E = F/ S, where S is the surface area. When calculating artificial illumination of industrial premises, the concept of mean illuminance usually applies to a horizontal plane 0.8 m above the floor level, also known as the workplace plane.

Old unit of illuminance was foot-candle which is the number of $lumens/ft^2$ or $1m/ft^2$. New unit is lux which is 1 $lm/^2$. Their relation is- .

1 foot candle .= I Im/ft^2 == 10.76 lux (or meter candle or $1m/^2$)
1 meter candle = 1 lux = 0.092 foot candle

Daylight Factor (**DF**) = lux/80

Illuminance level is a prescribed amount Illuminance.

Initial illuminance is the amount of illuminance obtained when the luminaries are neat and clean and when the lamps are first energized.

Service or maintained illuminance is the mean or average illuminance throughout the life of a lighting installation or over an extened period of time. This is lower than the initial illuminance for several reasons stated below.

Light loss factor is a factor which represents the average-to-initial illuminance ratio of a lighting system. It represents the depreciation and deterioration of a lighting system caused by following reasons:

1. Loss of lamp lumens due to aging effect.
2. Decrease in lamp and luminaire output resulting from dust, dirt, insects and chemical changes in the luminaire reflecting surface.
3. Increased absorption of the light output of the luminaries by dust, dirt and chemical changes in the room reflecting surfaces.
4. Differences between actual and design lamp voltages.

Standard illuminance is the service illuminance recommended for standard conditions.

Coefficient of reflection or Reflection factor is the ratio of the light reflected by the body to the incident light. Its symbol is ‘r’.

Coefficient of Utilization, or Utilization factor is the total flux received by a surface divided by the total flux from the lamps illuminating it.

Seeing or visual task is the object being regarded and its background.

Mounting height is the distance from the bottom of the luminaire to the surface used as a reference.

(E) **Luminance (Brightness)** is the luminous flux (directly seen by the eye) reflected by a surface in a given direction. Its unit is candela per sq. m. (cd/m?), and the symbol L. All other conditions being equal, the luminance is proportional to the illuminance i.e. L = lr/s, where r is the reflection factor of the surface, and is given by r = Fref/Ffal where Fref = luminous flux reflected from a surface and Ffal = luminous flux falling on that surface. It is also known as coefficient of reflection.

(F) **Background** is the surrounding surface, real or artificial, against which the object can be visualised or discerned. The background is said to be light if the reflection factor is greater than 0.4, semi-dark, if it is 0.4-0.2 and dark, if less than 0.2. Normal background is the surface behind object.

(G) **Contrast** is the relative luminance between an object and its background (e.g. a letter on paper) and its symbol is C. Where the background has aluminance L and the object a luminance L (L,>L,), it can be expressed C = (L1-L2)/L~. Contrast is a dimensionless magnitude ranging between 0 and 1. It may be high, soft or low.

(B) to (E) are quantitative and (F) & (G) are qualitative indices of illumination.

Digital light meter (photocell device) is available to measure light directly in lux.

For sufficient lighting, lighting level should be measured by lux (light) meter and than it should be compared with the standard lux level given in Part 4.

See Part 6.4 for figure.

3.2 General Principles of Good Lighting:

General Principles or requirements of good lighting are as follows :

1. Adequate illumination.
2. Avoidance of glare.
3. Avoidance of shadow.
4. Uniform lighting.
5. Appropriate contrast.
6. Appropriate colour contrast.
7. Colour effect and
8. Avoidance of flicker and stroboscopic effect.

These are briefly explained below :

See also part 6 for details of design principles

3.2.1. Adequate Illumination :

Adequate, rational or good illumination needs sufficient quantity of illumination necessary for avoiding discomfort to the worker and undue strain on eyes-

The **quantity or intensity of illumination** is given by luminous flux, luminous intensity, illuminance, luminance and reflection factor as explained in the foregoing part 3.1. Its requirement varies from place to place, person to person and with the age of person also. Therefore by experiments, standards of illumination are recommended for a variety of places and jobs to have sufficient quantity of light for better work performance. Such statutory standards and Indian standards are separately given in part 4 of this Chapter.

Visual acuity (sharpness of vision) increases with light intensity and is about equal to daylight acuity as 1000 lux is approached. However, this degree of acuity is seldom required and it is apparent that the desired amount of lighting will vary with the amount of detail required in the work. For example, for very fine work like distinguishing black thread on black cloth, intensity of 2000 lux is required but for exit road, car parking, storage area 20 lux is required.

Although individuals differ in amount of light they find most desirable, 65% of the subjects of one study judged intensity between 10 to 30 foot-candles or 100 to 300 lux, the most comfortable for reading.

The quality of illumination depends on three factors - diffusion, distribution and colour value. Regardless of the quantity of illumination, its effects may be impaired because of the unevenness, the glare or the faulty direction of the light.

Diffusion is the breaking up of a beam of light and the spreading of its rays in many directions by a surface. It is the process of reflection of -light by a reflecting surface or of transmission of light through a translucent material.

Thus adequate illumination requires sufficient quantity and good quality of light necessary for the work.

See Part 3.2.4 for uniform lighting.

3.2.2 Glare :

Glare is the condition in which brightness or the contrast of brightness interferes with vision.

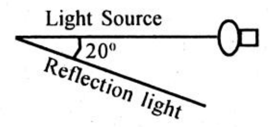
Glare is produced by excessive light stimuli i.e. excessive luminance in the field of vision which disturbs the adaptation process of retina.

Sometimes glare impairs the visual function, of the eye and reduces visual performance.

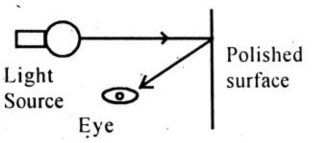
Glare causes discomfort, annoyance, eye fatigue and impairment of or interference with vision. It is produced by excessive light stimuli i.e. too much light which affects the adaptation process of the retina. It can be considered at three levels.(types)- (1) Direct or disability glare (2) Discomfort glare and (3) Indirect or reflected glare.

Direct or disability glare comes directly from the light source to the eye and impairs the ability to see clearly (e.g. dash on upward headlight of a car). This is due to excessive light focused on the eye and scattering of light inside the eye. It depends for its effects upon the position of the light source in the field of view and on the contrast in brightness between the light source and its background. It can be avoided by:

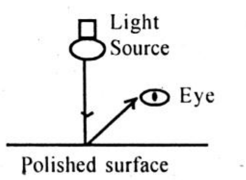
1. Provide diffuser over the lamp or reflector (screen) with minimum reflecting angle 20° below the horizontal, (dipper)



2. Reducing the brightness of the light source (e.g. by enclosing the lamp in bowl reflector).
3. Reducing the area of high brightness (e.g. by installing louvers below the light source).
4. Increasing the angle between the' source of glare and the line of vision i.e. by increasing the mounting height.
5. Decreasing the source of glare so as to lessen the contrast.



Discomfort glare is due to liberal (less) or bright (more) light. It causes visual discomfort without necessarily impairing the ability to see and may occur from unscreened windows in bright sunlight or when over-bright or unshaded lamps in the workroom are too strong in brightness for the workroom environment.

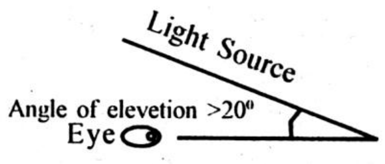


Reflected glare is glare that comes to the eyes as glint (flash) or reflection of the light source from some polished or shining surface. It is caused by a mirror image of the bright light sources reflected from shiny or wet workplaces such as glass or plated metal. These reflections distract or distort attention, make important detail difficult to see and reduce contrast or cause acute discomfort. It can be avoided by:

1. Changing the shining finish by matt finish.
2. Changing the task position or its surrounding.
3. Using light source of low brightness or providing lamp shade.
4. Arranging the geometry of the installation so that there is no glint at the particular viewing direction, e.g. increasing the source height.

5. Providing supplementary lighting.
6. Painting walls and ceiling with light colour so that surrounding becomes bright.
7. Increasing brightness to reduce relative brightness of the glare.

Rule 32 of the Gujarat Factories Rules prescribes, for the purpose of prevention of glare, that where any lighting source is less than 5 mt above floor level, no part of that light having brightness greater than 5 lamberts (1.5 foot candles=16 lux) shall be visible to persons normally working within 30 mt from that source, except where the angle of elevation from the eye to that source exceeds 20°. It is also suggested that local light (lamp on the job) shall be provided with opaque shade or effective screen to prevent glare in the eyes of workers working nearby.



Values of limiting glare index along with average illumination lux value are given in IS:6665 and Appendix D, Part 4 of National Electric Code.

3.2.3 Shadow :

Shadow affects the amount of illumination and is caused not by poor lighting but - by fixing light sources too wide apart or in wrong positions so that light is obstructed by some object. Light (faint) shadow may be allowed but dark (dense) shadow that conceals hazard or indicates wrong thing is not desirable, as it may cause accident.

Shadow on staircase, near door for entry or exit, near tool rack or on the work (job) table is not at all desirable and must be removed by providing extra or local light or shifting the light source or the object causing shadow.

Harsh shadows should be avoided, but some shadow effect may be desirable from the general lighting system to make more noticeable the depth and form o~ object. There are few specific visual tasks where clearly defined shadows improve visibility and such effects should be provided by supplementary lighting equipment arranged for the particular task.

3.2.4 Uniform Lighting :

The human eye can clearly perceive differences in luminance of over 50%. It takes time to adopt sudden variation in the intensity of lighting, particularly from higher to lower intensity. Uniform distribution of lighting is desirable. Distribution of light requires two problems to solve (1) uniformity of illummation and (2) elimination of shadows.

In uniform lighting, the distribution of light with a maximum and minimum illumination at any point should not be more than one-sixth above or below the average level in the area. Indirect lighting is the best method for producing uniform illummation. Here all the usable light is reflected light, high points of light from the bulb striking the eye directly are out of the visual field. The disadvantage of indirect light is its cost, since considerable light is lost through absorption. However its benefit is more worth than its extra cost.

3.2.5 Contrast:

The ability to see detail depends upon the contrast between the detail and its background. The greater the contrast, difference in luminance, the more readily the seeing task is performed. The eyes function most comfortably and efficiently when the luminance within the remainder of the environment is relatively uniform. Therefore all luminance in the field of view should be carefully controlled. 15:3646 (Part I & II) provide details for this. Reflectance should be maintained as near as practical to recommended values (For ceiling 80 to 90%, for walls 40 to 60%, for desks and bench tops, machine and equipment 25 to 45% and for floors not less than 20%). High reflectance surfaces are desirable to provide the recommended luminance relationship and high utilisation of light. They improve the appearance of the work place. It is also desirable that the background should be slightly darker or paler than the seeing task. Too much contrast is not desirable.

The contrast recognises the object easily and increases visual performance. If the difference between the object (job or seeing task) and its background is not noticeable, it is difficult to work. A black machine in black background (darkness) is difficult to notice. There should be a minimum contrast between the visual target detail and its background.

The differences in luminance of visual task, its immediate background and environment should not exceed certain maximum values i.e. a relationship of 10: 3:1 for normal tasks and 10 : 5 : I and 10 : 10 : I for precision work.

3.2.6 Colour Contrast:

Eye sees an object by the light it reflects and distinguishes its details mainly by colour contrast. Thus, in addition to luminance contrast, colour contrast may be influenced by the choice of the colour of light. The choice of the correct colour of light depends on the task to be performed and the requirements to be met by vision. It may be noted that there must not only be adequate illumination to see an object clearly, but also the object must be visible in its surroundings. It must have moderate colour contrast. The colour approximating to white will give better colour rendering and light yield. The colour approximating to red will give low Quality colour rendering but the light will create an emotional atmosphere.

A well painted machine inspires a feeling of personal pride and proper maintenance is encouraged.

3.2.7 Colour Effect:

It refers to the appearance of coloured objects when illuminated by a particular light source. It is the property of light which facilitates the perception of surface colours and depends on the spectral composition of the light. For example, red surface will appear red only, if the light falling on it contains red, but it will appear brown under the yellow of sodium street lighting.

The maximum value of the index is 100 and at this value there is no shift, i.e. the colour rendering is perfect. For example, an incandescent tungsten filament lamp has a colour rendering index of 100, fluorescent tubes between 55 to 95, mercury vapour lamps approximately 45 and low-pressure sodium vapour lamps less than 25. Where colour discrimination and colour matching are a part of the work process, the light source selected should have the desired colour rendering properties. .

3.2.8 Flicker and Stroboscopic Effect :

All lamps working on alternating current give light which pulsates at twice the supply frequency. This type of discontinuous light of almost all frequencies can produce (fleshing rapidly to show moving object stationary) effect, in which a rotating or reciprocating object can appear to be stationary, or moving slowly, or even appear to be rotating in the opposite direction etc. This false belief can cause accidents in the industrial situation. It is a real hazard in the presence of moving machinery. High intensity discharge lamps and fluorescent tubes have some 'flicker content in their light output at twice the mains frequency. The steps to diminish the stroboscopic effect are:

1. Light the moving object with lamps fed from two different out of phase a.c. supplies, or from two or three phases of a three-phase supply or lead lag luminaries.

2. Select a lamp with a low flicker characteristic, e.g. a fluorescent coated high-intensity discharge tungsten filament (GLS) lamp or ordinary filament lamp.

3. Add a local GLS lamp to augment the general lighting.

4. Use GLS or tungsten halogen lamps fed from a direct current (d.c.) supply.

5. Use the common twin-tube circuit.

4 RECOMMENDED STANDARDS OF ILLUMINATION

It is not a simple matter to specify suitable intensity levels based upon sound reasoning. As there is no fixed threshold level of illumination below which a visual task is greatly impeded, some compromise has to be made between an ideal level and adequate level. Generally a recommended level is arrived at after careful consideration of eyesight, the visual task, the environment and the economy involved. Any specification is therefore, opens to controversy, the recommended level, however, serves chiefly as a guide to good practices. Standard illumination benefits people with normal sight and helps to faulty vision. It can be achieved through a combined usage of day lighting and artificial lighting and maintained by proper cleaning and re-lamping etc.

Importance of illumination level:

Illumination, noise, temperature and other environmental conditions such as chemical exposure and vibration play an important role in the ability of humans to interact effectively with equipment or a system.

Lighting is an important element in the design of any system as improper lighting levels may cause system elements to be seen incorrectly or not seen at all. Improper-illumination level may result in the eye strain, muscle fatigue, headache or accidents.

The adequacy of lighting depends upon the type of lighting provided, its quality and quantity, the age of the worker and visual requirements of the task or system.

Illuminance ranges

Circumstances may be significantly different for difficult interiors used for the same application or different conditions for the same kind of activity. A range of illuminance is recommended for each type of interior or activity. Each range consists of three successive steps of the recommended scale of illuminance. Middle value of each range, represents the recommended service illuminance that would be used unless one or more of the factors mentioned below apply.

Higher value of the range should be used when:

1. Unusually low reflectance or contrasts are present in the task.
2. Errors are costly to rectify.
3. Visual work is critical.

4. Accuracy or higher productivity is of great importance.
5. The visual capacity of the worker makes it necessary.

The lower value of the range should be used when:

1. Reflectance or contrasts are unusually high.
2. Speed and accuracy is not important.
3. The task is executed only occasionally.

Depending upon importance of the work, illumination level must be according to the standards mentioned below.

4.1 Statutory Provisions :

Section-17 of the Factories Act requires sufficient and suitable lighting, natural, artificial or both and prevention of direct or reflected glare and shadows causing eye strain or risk of accident.

Rules 30 to 34 of the Gujarat Factories Rules prescribe further details. General level of 30 meters candles (30 lux) or more at the horizontal level of 91.4 cm (3 feet) above the floor is prescribed. Where the light source is above 7.6 meter height from the floor, at least 10 meters candle minimum illumination should be available. It should be at least 30 meters-candles (30 lux) where the work is actually going on. Walkways require at least 5 meter candles (5 lux) at floor level. Rule 32 describes details to prevent glare, (see Part 3.2.2)

Minimum illumination levels prescribed by **Rule** 35 of the Maharashtra Factories Rules is given in Table 9.2

Table 9.2 : Minimum Illumination Levels u/r 35 MFR

S. No.	Area / Workroom	Minimum Intensity of Illumination in Lux
1	Stock-yards : main entrance and exit roads, cat-walks of outdoor plants, coal unloading and storage areas.	20
2	Passage-ways, corridors and stairways, warehouses, stock' rooms for large & bulky materials, platforms of outdoor plants, basements.	50
3	Engine and boiler rooms, passengers and freight elevators, conveyor crating & boxing departments, storerooms for medium and fine materials, locker rooms, toilet and wash-rooms.	100
4	Where discrimination of detail is not essential (e.g. handling of material of coarse nature, rough sorting, handling coal or ashes etc.)	50
5	Where slight discrimination of detail is essential [e.g. production of semi-finished iron and steel products, rough ; assembling, opening, carding drawing, spinning (ordinary) counts of cotton].	100
6	Where moderate discrimination of details is essential (e.g. medium assembling, rough bench work and machine work, inspection and testing of products, canning, sawing, sewing of light coloured textiles and leather products, weaving light	200

	thread, warping, spinning fine counts).	
7	Where close discrimination of S detail is essential (e.g. medium bench and machine work, fine testing, .flour grading, leather finishing, weaving cotton goods or light coloured woollen goods, welding sub-assembly, drilling, rivetting, book-binding and folding).	300
8	Where discrimination of fine detail is involved under a fair degree of contrast for long periods of time (e.g. fine assembling, fine bench and machine work, fine inspection, fine polishing and bevelling of glass, fine wood working, weaving dark coloured woollen goods).	500
9	Where discrimination of extremely fine detail is involved under conditions of extremely poor contrast for long periods of time. (e.g. extra fine assembling, extra fine inspection, jewellery and watch manufacturing, grading and working of tobacco products, dark cloth hand tailoring, final perching in dye works, make-up and proof-reading in printing plants).	1000

4.2 Indian Standards :

SP 32 a Handbook on functional requirements of industrial buildings (lighting & ventilation) may be referred.

Some useful IS are given in Table 9.3 : Table 9.3 : Indian Standards on Lighting

S. No.	Area / Workroom	Minimum Intensity of Illumination in Lux
1	Industrial lighting	6665
2	Day lighting of factory buildings	6060
3	Day lighting of buildings	2440
4	Principles of good lighting and aspects of design (Part I)	3646
5	Schedule for values of illumination and glare index (Part II)	3646
6	Calculation of coefficient of utilization by the BZ method (Part III)	3646
7	Eletro technical vocabulary Part 16	1885
8	Flameproof electric lighting fittings	2206
9	Dust – proof electric lighting fittings	4012
10	Dust-tight electric lighting fittings	4013
11	Miners' Cap-lamps	2596

Out of 63 types of industrial buildings and processes, only 15 are selected from Table-2 of 15:6665 and given in Table 9.4 as a sample recommendation.

Table 9.4 : Recommended Values of Illumination (IS : 6665)

S. No.	Industrial buildings and processes		Average Illumination Lux
1	**General Factory Areas:**		
	a	Canteens	150
	b	Cloakrooms, Entrances, Corridors & Stairs	100
2	**Factory Outdoor Areas:**		

	Stockyards, main entrances, exit roads, car parking, internal factory roads		20
3	**Assembly Shops:**		
	a	Rough, work, for example, frame assembly, assembly of heavy machinery	150
	b	Medium work, for example, machined-part, engine assembly, vehicle body assembly	300
	c	Fine work, for example, radio and telephone equipment, typewriter and office machinery assembly.	700
	d	Very fine work, for example/assembly of very small precision mechanism, instruments	1500
4	**Boot and Shoe Factories :**		
	A	Sorting and grading, Cutting table and presses stitching	1000
	B	Clicking and closing, preparatory operations, bottom stock preparation, lasting and bottoming, finishing and shoe rooms	700
5	**Canning and Preserving Factories :**		
	a	Inspection of beans, rice, barley etc.	450
	b	Preparation : kettle areas, mechanical cleaning, dicing, trimming, high speed labelling lines	300
	c	Cam-led and bottled goods :Rotors.	200
	d	Can inspection	450
6	**Chemical Works:**		
	a	Hand furnaces, boiling tanks, stationery dryers, stationery crystallisers, dryers, filtration inechanical bleaching, percolators, or gravity mechanical evaporators, plants, crystallising, extractors, nitrators, electrolytic cells.	150
	b	Controls, gauges, valves, etc.	100
	c	Control rooms: Vertical control panels & Control desks	200 to 300
7		**Die Sinking :**	
	a	General	300
	b	Fine	1000
8		**Engraving :**	
	a	Hand	1000
	b	Machine (see Die Sinking)	-
9		**Foundaries**	
	a	Charging floors, tumbling, cleaning, pouring, shaking out, rough moulding and rough core making.	150
	b	Fine moulding and making inspection.	300
10		**Inspection Shops (Engineering):**	
	a	Rough work, for example, counting, rough checking of stock parts etc.	150
	b	Medium work, for example, 'Go' and 'No-Go' gauges, sub-assemblies.	300
	c	Fine work, for example, radio and telecommunication equipment, calibrated scales, precision mechanisms, instruments.	700
	d	Very fine work, for example, gauging and inspection	1500

		of small intricate parts.	
	e	Minute work for example, very small- instruments	3000
11		**Iron and Steel Works :**	
	a	Marshalling and outdoor stockyards	10 to 20
	b	Stairs, gangways, basements, quarries, loading docks, slab yards, melting shops, ingot stripping pits, blast furnace working areas, picking and cleaning lines mechanical plants, pump houses.	100
	c	Mould preparation, rolling and wise mills, mill motor rooms, power and blower houses.	150
	d	Slab inspection and conditioning, cold strip mills, sheet and plate finishing, tinning, galvanizing, machine and roll shops.	200
	e	Plate inspection	300
	f	Tinplate inspection	Special Lighting
12		**Laboratories and Test Rooms :**	
	a	General laboratories, balance rooms	300
	b	Electrical and instrument laboratories	450
13		**Machine and Fitting Shops :**	
	a	Rough bench and machine work.	150
	b	Medium bench and machine work, ordinary automatic machines, rough grinding, medium buffing and polishing.	300
	c	Fine bench and machine work, fine automatic machines, medium grinding, fine buffing and polishing.	700
14		**Paint shops and Spraying Booths :**	
	a	Dipping, firing, rough spraying.	150
	b	Rubbing, ordinary painting, spraying and finishing.	300
	c	Fine painting, spraying and finishing.	450
	d	Retouching and matching.	700
15		**Sheet Metal Works :**	
	a	Benchwork, scribing, pressing, punching, shearing, stamping, spinning, folding.	200
	b	Sheet inspection.	Special Lighting

4.3 ILO Recommendation:

As given by ILO Encyclopaedia of Occupational Health and Safety, some recommended illuminance are given in Table 9.5.

Table 9.5 : ILO Recommendation

Class of Visual Task	Typical Examples	Recommended Illuminance (Lux)
1. Exceptionally difficult tasks	Inspection of minute work, jewellery, watch-making, hosiery, knitwear.	2400 or more
b. Very difficult	Extra-fine bench and machine work, tool & die making examining of dark goods, dye works - final perching.	1600
	Clothing trade-inspection, hand tailoring, grading	1200

	and matching dark leather, dye-works-colour matching.	
3. Difficult	Fine bench and machine work, extra fine painting, spraying, matching, dye works-reception, grey perching.	800
4. Normal range of task and work-places	Office work with poor contrast, drawing office, fine painting, proof-reading, computer rooms.	600
5. Moderately difficult	Medium bench and machine work, typing, filing, reading, writing, wood working, steel fabrication.	400
6. Ordinary	Chalkboards & charts, pharma-stores, bottling & canning plants, book binding, food preparation, cooking, canteens	300
7. Simple	Rough bench and machine work, counting, checking, halls, waiting rooms, warehouses, stores, parking, dispatch.	200
8. Rough intermittent tasks	Live storage, rough bulky material, loading bays, change / locker rooms.	100
9. Movement & Orientation.	Corridors with heavy traffic, walkways, stairs, rest-rooms, lanes.	50
	Corridors with light traffic	20

5 TYPES OF LIGHT, SOURCES, FITTINGS AND INSTALLATIONS

5.1 Types of Light (Lighting) :

Day lighting and artificial lighting are the main types. Other classification is minor. Most people prefer to work in day-light i.e. natural or general light. However in a large shed or for work indoors, natural light is not fully available in whole area and for the whole working day. In that case, it needs to be supplemented by an artificial or electric lighting. Automatic or manual control systems are available to vary the output of electric lighting necessary to complement the daylight and maintain the recommended (set) level.

Lighting is also classified as general, supplementary, direct, semi-direct, indirect, semiindirect, diffused etc. depending upon its nature, reflection or way of utility.

General lighting is that quantity and quality of day lighting which alone provides the recommended standard of illumination.

Supplementary lighting is that additional artificial (electric) lighting needed to meet the required standard or particular demand of any job. For this purpose supplementary luminaries are used to provide higher illumination levels for small or restricted areas. Also they. are used to furnish a certain luminance,

colour or to permit special aiming or positioning of light sources to produce or avoid highlights or shadows to best portray the details of the task. At the dark spots, supplementary lighting is required. Permanent supplementary artificial lighting (PSAL) in buildings is required where adequate day lighting over tile whole working area is not available and to create acceptable brightness levels on the various surfaces in working interior.

Diffused or reduced light through some surface should be sufficient otherwise it may cause discomfort or eye-fatigue.

Security or Protective Lighting is required in bordering areas and security points for night-time policing. It will show and restrict entry of intruders. It is of four types - floodlights, street lights, fresnel lens units and searchlights. It may be required at the time of evacuation of people in case of emergency. Alternate power source (e.g. DG set) should be connected to emergency or protective lighting.

Floodlights provide area lighting at an economical cost. They must be located at suitable mounting heights and with unobstructed beam paths. Mounting can be on pipe or pole, platforms, rigging structures etc. Floodlights are of lamp types and with beam spreads from 10 to 18 degrees.

For direct, indirect and semi direct/indirect lighting see part 5.1.3.

5.1.1 Day, Natural or General Lighting:

In our country natural sun light available during most of the days is called daylight or day lighting. Its varying intensity from sunrise to sunset provides harmonious variation of the visual environment inside or outside a building and is normally welcomed for the visual task. It is the cheapest light and should be effectively utilised by proper design of roof, doors, windows and ventilators. Generally northlight roof, also known as saw toothed roof or pent roof, is a more efficient way of getting daylight without glare and heating by direct sunlight. The standard size windows should be provided on both sides opposite to each other to obtain better and uniform illumination throughout the area. It provides cross-ventilation also.

Windows, monitor (louvers) roof and the north light roof are generally preferred for day lighting. In our country mostly north-light (saw tooth type) roofs are preferred in the northern hemisphere. Such design keeps off direct mid-day sun in latitudes north of 23". Transparent high density plastic or FRP sheet (plain or corrugated) is provided, in roof at certain intervals. Transmission coefficients of some such materials are given in Table 9.6.

Table 9.6 : Transmission Coefficients (for visible light) for some glazing materials (IS : 6060)

	Material	**Trans. Coeff.**
1	Transparent window glass	0.80 to 0.85
2	Clean acrylic plastic sheet	0.85 to 0.80
3	Patterned glass	0.70 to 0.85
4	Clear rigid PVC	0.80
5	Wired rigid PVC	0.75 to 0.70
6	Sand blasted glass	0.80 to 0.65
7	Wired finish glass	0.80 to 0.60
8	Corrugated glass fibre reinforced sheet	0.80 to 0.55

Proper, utilisation of day lighting to get appropriate illumination levels on the working plane in factories will result in considerable economy consistent with efficiency of production and worker's well-being. The Central Building Research Institute, Roorkee carried out research and measurements of daylight requirements for factory building and IS:6060 is prepared on the basis of its investigations.

One research has shown that artificial lighting in the absence of natural (day) light, affects the autonomous nervous system. Therefore artificial (electric) lighting should be controlled in accordance with the variations of daylight.

See also Part 6.2.

5.1.2 Artificial Lighting:

During night time i.e. in the absence of daylight, artificial light is the only remedy. Even during day time where the day lighting is insufficient to provide prescribed illumination due to any obstruction or weather effect, it will be necessary to supplement the natural lighting by artificial lighting designed to operate permanently during day time. It should be properly co-ordinated with natural lighting as per 15:3646 (Part 1). The combination of day lighting and artificial lighting is known as twilighting.

Types of artificial light depend on types of artificial (viz electrical) light sources or their fixtures. Lighting from electric lamp or tube or from many types of their combination gives a verity of artificial lighting. For detail see Part 5.2 and 5.3.

See Part 6.3 for installation of artificial lighting.

5.1.3 Direct and Indirect Lighting

Direct Lighting means light falling on object directly from source - natural or artificial. Thus direct light from Sun or electric tube on the job or book is called direct lighting. Its first reflection is to the eye, therefore, it should not be excessive, otherwise it may cause reflected glare or eye strain. Local light (lamp) hanging on machine is a direct light. Direct artificial light requires less electric power consumption than the indirect artificial light for the same brightness required.

Indirect lighting is reflected or diffused light coming after reflection of light from some surface or coining through some transparent surface. Its benefit is to avoid direct glare and to make the light of comfortable brightness.

Semi-direct or semi indirect light is a combination of direct and indirect light. Direct light from window and simultaneously reflected light form a lamp is of this type of light. Where direct or indirect light, is insufficient, lighting level is increased by this type of combination.

5.2 Types of Light Sources:

It is interesting to note that electric lamps produce more heat than light as follows:

Type of Lamp	Heat (%)	Light (%)
Incandescent	97	3
Fluorescent	90	10
Sodium Vapour	80	20

Other types and lamp data are given in Table 9.7.

Table 9.7:. Lamp Data

Type of Lamp	Luminous Efficiency lumens / watt	Bulb life Hours	Colour Rendering Index
Incandescent GLS or PAR Tungsten-filament	12-22 10-13 13-18	1000 10000	100 50-69
Tungsten-halogen (T-H)	20-27 14-22	2000	70-84
Fluorescent Tube White Tubes	75-95 50 62-66	5000 5000	55-75 85-95 56

Triphosphor	69-70	7500	85
Mercury Vapour Lamps High Pressure (HPMV) with fluorescence MBI	55 35-50 63-72	3000 5000 6000 7500	25 45 70-84
Sodium Vapour Lamps Low Pressure (SOX) High Pressure	110-140 95	4000 8000	20 45
Metal halide lamps	75-125	3000 to 20,000	

Apart from above factors, the selection of light source also depends on -

1. Type of application.
2. Atmospheric conditions of industrial interiors and/or exteriors.
3. Surface features.
4. Initial outlay.
5. Running cost.
6. Ease of maintenance.

Types of lamps are:

Incandescent filament lamps including tungsten and halogen are simple, compact, versatile and suitable where artificial lighting is occasionally required, space is restricted and a powerful concentrated beam of light is required. Short life and low efficiency are their disadvantages.

Halogen lamps are mainly used for terrain lighting and as automobile head (driving) lights.

Fluorescent lamps or tubes are good for medium height ceilings and general uniform lighting whereas for highways HPMV lamps or their combination with tungsten filament lamps are used. Generally fluorescent tubes are preferred because of their higher efficiency, long life, low brightness, minimum glare and shadows, colour rendering close to daylight, less heat and linear form. They are mostly required for regular artificial light, good colour rendering effect and increasing illumination level.

Mercury vapour lamps, colour corrected, are more suitable and economical in a large, lofty building (viz. steelworks) having high height and also for exterior lighting of storage areas, clocks, roadways etc. If colour rendering is not important, ordinary uncorrected mercury lamps may be used.

Sodium vapour lamps are seldom suitable for interior lighting due to their poor colour rendering properties. Low-pressure sodium lamps are used for terrain and road lighting and also in high halls where colour rendering is not demanded. High pressure sodium lamps are also developed to improve colour rendering.

High-pressure sodium lamps have efficacies that range from 77 lumens per watt to 140 lumens per watt, depending on size. The colour rendition is a distinct orange. Warm-up time for high-pressure sodium lamps is from 3 minutes to 4 minutes. Restrike time is less than I minute, and instant restrike devices are offered for 50-watt to ISO-watt high-pressure sodium lamps. Power factors range from 40 percent to 99 percent depending on the heavy type and the age of the lamp. Lamp life is 24,000 hours.

Metal halide lamps are similar in construction to mercury vapour lamps. The difference is that metal halides are added to the mercury and argon in the arc tube. The efficacies are improved to the range of 75 lumens per watt to 125 lumens per watt, excluding ballast loss. The colour rendering is quite white and is usually superior to the phosphor-coated mercury vapour lamp. The warm-up time for metal halide lamps is 2 minutes to 4 minutes, and re-strike time varies from 5 minutes to 15 minutes, depending on the type. Power factors in the range of 90 percent can be obtained. Lamp life varies from 3000 hours to 20,000 hours. Metal halide lamps have more rapid lumen depreciation than do mercury vapour lamps and have high surface operating temperature which must be. considered before application in classified locations. The lamp life and lumen output are affected by burning position.

Compared with incandescent lamps, mercury vapour lamps offer the advantages of longer average life and higher lumen output; however, with the advent of metal halide and high pressure sodium lamps, the mercury vapour lamp is considered by many to be obsolete, except in existing plants .having similar lamps. The mercury vapour lamp is considered obsolete because of its rapid lumen depreciation and low lumens-per-watt characteristics.

Mercury vapour, or mercury-halide lamps, tubular fluorescent and sodium vapour lamps are generally called 'electric discharge lamps' as electric current is passed through certain gases to produce emission of light.

From above types the mercury vapour lamps take up to 6 minutes and sodium vapour lamps take up to 20 minutes to reach their maximum output, the actual time will be determined by the wattage of the lamps. In the event of a power failure, restoration of power will immediately start machinery, while discharge lamps would take 'warming time' to relight. This time gap may cause accident due to insufficient lighting. To avoid such situation emergency lighting is a must which will glow during power absence.

Selection of the type of light source depends on efficiency, installation, running costs, maintenance, life characteristics, size, robustness and heat & colour output. The efficiency of any lamp is the light output per unit of electricity consumed and is measured in lumens per watt. For example, it is as under:

Type of Lamp	Lumnes per watt (approx.)
Incandescent lamps	15
Tungsten halogen	22
High pressure mercury	35-55
Fluorescent lamps	75-95
High pressure sodium	100

Incandescent lamps are cheaper but they are more expensive than other types of lamps to run and they require frequent replacement. Discharge and fluorescent lamps cost more to install but their greater efficiencies and longer life make them more suitable for general interior lighting.

Where colour performance is important, the tubular fluorescent lamp is more suitable and not the mercury or sodium vapour lamp. Where lighting is required at height (e.g. overhead crane in workshop) the high pressure discharge lamps are more suitable.

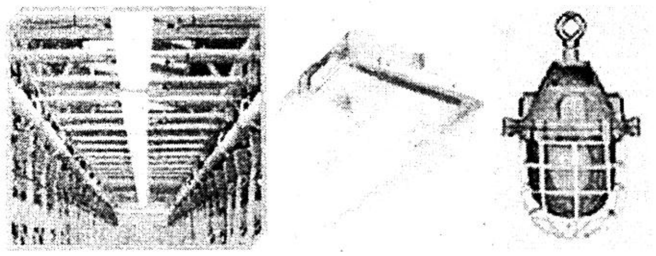
Where artificial lighting is supplied, hazards of electricity must be identified and removed. Loose wiring, faulty switches or fuses, un-insulated wire or cable, open switch box, open wire in plug, many joints in phase wire etc. arc sources of danger with electric lighting. Safe lighting is low voltage lighting (allowing low current at the same resistance E = IR) -or solar lighting-

Similar precautions are also necessary while providing lighting in hazardous areas. Dust, dampness, flammable/explosive atmosphere, corrosion etc. require standard flameproof electric lighting. Electric equipment/tool should also be of the approved type. See Chapter-11 for details.

5.3 Types of Lighting Fittings:

Luminairc is a general term used for all the apparatus necessary to provide a lighting effect. It includes all components for the mounting and protection of lamps and connecting them to power supply i.e. the whole lighting fitting.

In selection of a luminaire (lighting fitting), a separate study should be made for each application. Factors influencing the selection are appearance, efficiency, glare, density of equipment, frequency of operation, maintenance, required colour rendition and hazardous area classification.



The lighting fillings or fixtures are of many types, viz. bare, reflector type (direct), direct-indirect, louvered diffused, diffused panels, local lighting units, hand lamps and flame proof and dust proof fittings for hazardous areas. Hand lamps should be of low voltage = 24 V and flameproof if it is to be used in flammable area. It should have a lamp guard and an insulated (non conductive) handle. Some typical general lighting units are as follows:

1. **Industrial type troughs and shades:** These have small slots which allow at least 10-15% of the light to escape in an upward direction. This will be sufficient to dispel overhead gloom and also ensure adequate ventilation of the fitting, thus helping to prevent dirt from collecting inside.

2. **Totally-enclosed diffusing units :** Units of this type provide high quality lighting and the incandescent varieties are by far the best type to use when an office is to be lit with incandescent lamps. The fluorescent version gives comparatively little upward' light and for this reason it should be ceiling-mounted rather than suspended.

3. **Louvers fluorescent units :** These may have metal louvers, or translucent diffusing ones. If suspended from the ceiling, at least some of the lamps should emit unobstructed upward light. Such units are generally less affected by airborne dirt than totally enclosed types.

4. **Direct-Indirect units :** The essential features of this type of unit is the pair of large apparatus (some 2 or 3 inches wide) above the lamps. These large slots allow some 40% of the available light .to escape to the ceiling and for this reason it is convenient to refer them as "40/ 60" fittings (this being the relative proportions of upward and downward light). Being made entirely of metal, such fittings are frequently cheaper than the enclosed diffusing type.

5. **Bare fluorescent lamp units :** If the room is very small (so that all lamps are well up out of the field of view of the occupants) they can be safely used. They can also be sometimes employed in long narrow room where everyone views the units more or less on end.

6. **Recessed units :** In offices with low ceilings, it is often necessary to recess the lighting fittings, leaving the mouth flush with the ceiling. In such cases light from the fittings can only reach the ceiling by reflection and the system is most likely to be satisfactory when the room is small in. size, with a light decoration scheme or when the general illumination is reasonably high (at least 50 lm/sq. ft or 500 lux).

7. **Luminous and louvered ceilings :** In general, a louvered ceiling gives better visual conditions than a luminous ceiling made of continuous sheets of diffusing material. A uniformly bright luminous ceiling tends to produce excessively diffused lighting which is apt to make the interior look dull unless the illumination level is particularly high.

8. **Incandescent lamp units:** Deep shades should be used and a black band should preferably be painted round the inner edge of adjustable shades which may be set at an angle.

Hand lamps should be of a well designed, strongly constructed type. The lamp socket should be properly shrouded and insulated from the wire guard. Low-voltage incandescent lamps are more efficient and robust than equivalent mains voltage types. They are safer to use, provided that the supply transformer is properly insulated and earthed, preferably at the centre point of the secondary winding. In particularly dangerous situations (e.g. inside a metal tank or boiler shell) the lamp voltage should preferably be below 24 volts, with centre-point earthing to reduce the maximum potential to earth to 12 volts.

9. **Fluorescent lamp units:** Troughs should be mounted either low enough to ensure, that all bright surfaces are completely hidden, or high enough to ensure that they are well outside the normal field of view.

5.4 Types of Lighting Installations:

The term lighting installation includes types of lighting, light sources and fittings just mentioned in foregoing parts 5.1 to 5.3. It is a broad term describing overall artificial lighting arrangement.

Generally lighting installation is classified as :

1. Uniform general lighting.
2. General plus local supplementary lighting.
3. Localised general lighting and
4. Special purpose lighting (ultraviolet lamp etc.).

Uniform general lighting should be (1) as high as possible to avoid glare (2) spaced evenly proportional to mounting height and(3) uniform and not less than 2/3 of average anywhere. If mounting height is H, then distances of spacing of rows, close to wall and gangway along a wall should be 1.5 H, 0.5 H and 0.75 H respectively. Uniform general lighting is suitable in place where the work points are not fixed e.g. foundries, large assembly shops, warehouses etc.

In general plus local supplementary lighting, additional local units (usually mounted close to the work point) supplement the evenly distributed general lighting provided by overhead units. The system is required at a few definite scattered locations and where light from overhead installation cannot reach the work point e.g. inside the throat of a heavy power press, inside hopper on point of operation etc.

Generally die average illumination should not be less than the square root of the illumination on the locally lit task.

Locally general lighting is provided by overhead units on individual work benches or machines requiring strong illumination. Desks tables or machines should be lighted from side rather than from directly in front.

5.5 Cost of Lighting :

Old data of cost of lighting, in 1965-66, in 24 German factories was 2% of the wage bill. It was 1.4% UI 10 British factories. It may be assumed around 1.5% of the wage bill of a factory. Lighting cost is the sum of...

1. Cost of fittings x depreciation (@ 10%).
2. Cost of lamps/tubes.
3. Cost of electricity.
4. Maintenance cost.
5. Installation cost = 3 to 6% of the total electrical installation cost (with 10% depreciation cost).

This gives a rough estimate. More correct method incorporating new (latest) factors should be considered.

Economic Effect

1. High level of lighting increases overall costs but out-weighted by increased productivity and lower accident rate.
2. Lower standard of lighting can be accepted when specified, depending on the importance of Area.
3. Overall cost can be reduced by using lamps having a high luminous efficacy and suitable light distribution.

6 DESIGN OF LIGHTING INSATALLATION

Eight points discussed m foregoing part 3.2 are most important to design effective lighting installations. Particularly principles of illumination and utility of types of light, sources and fittings must always be considered while designing factory building and interior/exterior lighting arrangement. Selection of lighting fittings should consider

1. Luminance or brightness.
2. Design of luminaries (1) to avoid glare and shadow under normal seeing conditions (2) to produce highest initial and sustained light outputs.
3. Mechanical construction which can be conveniently installed and repaired.
4. Suitability for normal use and special areas like indoor or outdoor and hazardous (classified) areas.
5. Direction of incidence of light and shadow effect.
6. Colour appearance and colour rendering.
7. Its contrast with the background.
8. The duration of the visual work.

The quality requirements of the lighting increase with difficulty of the visual task. The light distribution of fittings should be as uniform as possible so as to avoid difference in brightness that would be disturbed because continuous / constant change in adaptation of the eye causes premature fatigue. Therefore overall illumination must be as constant as possible.

Normally five types of systems are available direct, semi direct, general diffuse, semi-indirect and indirect. Choice should be as per requirement and may be mixed.

6.1 General Considerations :

These are :

1. Make the task easy to see by providing sufficient light on the work. Troublesome reflections must be avoided.
2. Provide comfortable seeing conditions by eliminating glare, gloom and unwanted shadows. Use well designed lighting fitting with correct spacing and placing. Use suitable light reflecting colours.
3. Keep the installation in. good working order by providing safe and easy means of access, service and maintenance.
4. Select the best illumination level by considering the recommended standards. To assess this need of light consider: (a) quality of eye as an optical instrument (b) level of illumination (c) size, type and speed of the object and work (d) contrast between the object and its background (e) colour contrast (f) available perception time and (g) problem of glare and shadows.
5. Cost of lighting should not result in such an economy to raise indirect cost due to discomfort, damage and accidents.
6. Select flameproof/dustproof and non-corrosive light fitting where they are specifically needed.
7. Pay more attention on inspection areas requiring continuous close observation.
8. Select good lighting for building sites and internal roadways. Use of tungsten halogen floodlights, because of their small size and low cost, permits a temporary installation to be made quickly and easily.

For good design, it is important to seek cooperation between architect, occupational hygienist and lighting engineer to avoid errors from beginning. From the design stage, the planning should include appropriate light distribution and colour layout of the work areas and for that purpose-the type of lamps, luminance distribution, luminous efficiency and spectral composition of light should be considered.

Lighting installations should be designed to meet the conditions peculiar to the tasks of each area. Standard (recommended) illumination levels serve only as a guide to good lighting practice. Obviously depending on work required, illumination should be increased on the task.

6.2 Day lighting of Factory Buildings:

Some design principles are :

1. The design of openings, glazing and similar sources of daylight should be so positioned as to give illumination levels given in Table-1 of IS:6060. The value of sun (sky) light is @ 16000 lux.
2. Usually north lights are employed to provide requisite illtlmination on the working plane. Location of work should be such as to avoid glare from the north light glazed openings.
3. Where work is carried out during dark evening or morning hours, the day lighting should be combined with artificial lighting in such a manner that the reduction of daylight is unnoticeable specially for those engaged in precision work involving eye strain.
4. A careful interpretation of daylight factor (divide lux value by 80 to get daylight factor - DF) should be made before designing the fenestration. Normally factories should be designed to give atleast 1.25 DF.

5. Obstructions like structural members, overhead installations, vertical and horizontal machines and the like should be considered in relation to the glazing. It is essential to foresee the proposed layout orf the machines, as ignorance of this aspect is likely to cut down the light reaching the work plane.
6. There should be a good distribution of light over the whole interior. Lighting affecting one person or one group should be avoided. Light colours should be preferred on the interior surfaces". In case of north light roof truss, shadows caused at working planes by machines and operators can be minimised by providing openings in the side walls and/or by use of light coloured finish for ceiling surfaces.
7. Work should be so located as to avoid glare from the north light glazed openings.
8. The uniformity of illumination on the working plane in a north light factory depends on the width of the bay (distance between the north light openings), the slope of the roof and the reflectance of the ceiling.
9. Other types of north lights such as sawtooth, cylindrical shell or folded plate north light roofs should be designed properly.
10. Side-lighting is similar to vertical windows. Methods given in IS:2440 should be followed. The same IS also suggests the design time for horizontal or inclined roof lighting. Diffusing glasses can be used to diffuse the combined illumination due to sun and the sky light.

6.3 Installation for Artificial Lighting:

Foregoing parts 5.1.2 and 3 to 6.2 must be considered while designing for artificial lighting. As daylight is varying according to day hours, distances and weather effects, design of supplementary artificial lighting should be made from the initial planning. Some factors of consideration are :

1. Determine the quantity and quality of illumination desirable for the work.
2. Based on that, select lighting fitting by examining photometric characteristics and mechanical performance that meet installation, operating and maintenance conditions.
3. Select and arrange these fittings so that it will be easy and practical to clean and maintain them.
4. Balance, all the economic factors including initial, operating and maintenance costs, versus the quantity and quality requirements for optimum visual performance.
5. Control the light to control glare, shadow, distribution and diffusion.
6. Luminaries with some upward components of light are preferred for most area because an illuminated ceiling or upper structure reduces luminance ratios between luminaries and the background. The upward light reduces the 'dungeon' effect (feeling underground) and creates cheerful environment.
7. Higher mounting heights (out of the normal field of view), better shielding of the light sources and top openings in luminaries to allow to move dirt particles upward should also be considered.
8. Where false ceiling is provided, the lighting fittings may be recessed in the ceiling giving a more streamlined appearance to the whole installation.
9. Generally a continuous mounting of tubular fluorescent tubes fitting is preferred to an arrangement of reflectors at intervals.
10. The fittings should be fixed to the existing members of the roof structure and should be oriented according to the layout of the machinery to obtain most satisfactory result. The trenching system (metal channels with cover plates at the bottom, of standard lengths joined together) running across the hall with suspensions at necessary intervals is also preferred.
11. Illumination values and brightness ratios must be carefully controlled so that workers in one part of the factory are not subjected to higher brightness than they see in their immediate surroundings.
12. Contrasts between the high brightness of glazing and the dark solid surface around it should be minimised.

Calculation of Artificial Lighting : Following four methods are in use to calculate artificial-lighting installations in industrial buildings.

1. **The Light Source Point Method :** It is applied to calculate lighting fixtures where light sources are localised. Illuminance of inclined planes and uniformity of general illumination (exclusive of reflected flux) are determined.

2. **The Wattage Method :** It is simple and uses the formula W = PS/N, where W is the wattage of a light source in watts, P is the power density in watts/ 2, S is the surface (room) area in MZ and N is the number of light sources (lamps) in the lighting fixture. The values of P are available from appropriate tables.

3. **The Graphical Method :** This method of Prof. Trukhanov is most useful when light sources are projectors. It uses specialised nomograms.

4. **The Method of Light Flux Utilisation Factor :** It is most useful to calculate general uniform lighting in industrial building. It uses the formula F = ESKZ/UN where, F = light flux (lx), E = illuminance (lx), S = area of enclosure (m2), K = correction factor for the luminary's soiling (from a table), Z = the lighting nonuniformity coefficient, U = the light flux utilisation factor of a lighting fixture and N = .the number of lighting sources (lamps). The method takes into account both the direct light from the luminaries and the light reflected from the walls and the ceiling.

6.4 Plant Lighting Design:

Entire plant lighting shall be divided into following three categories.

(a) Normal AC lighting.

Normal lighting panels shall be supplied by three phase and neutral 415 V power derived from Main lighting distribution boards. LDB shall be supplied from PCC/MCC.

(b) Essential AC lighting.

Critical lighting will be provided on escape route within the control room building, substation building etc. These lights will be normally 'OFF' & Turn 'ON' automatically only on complete Power failure.

Essential light will remain energised all the time.

(c) Critical DC lighting.

The critical lighting shall be supplied by 220 V DC system having battery back-up.

Essential lighting panels shall be supplied in the same manner as the normal lighting panels but from the emergency board which has the back up of a stand by Power.

Portable emergency lights with built-in battery and battery charger shall be provided at strategic locations in building like Administrative building, Main control room. First Aid Centre, Fire Station, Warehouse, Workshop etc.

As far as possible the distribution boards shall be split so that loss of one board will not darken the area completely.

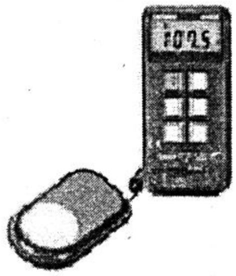
Building such as Substation, Control room, Office building. Canteen etc. shall be illuminated by fluoreocent fixtures. Process area shall be lighted by HPSV/HPMV/lamp fixtures. HPSV/HPMV lamps shall be used for yard and street lighting. Street lighting shall be automatically controlled by syncronizing timer. Tallest structures shall have aviation warning lighting as per statutory regulations.

All lighting fittings and associated conduit fittings shall be of a fully weather proof type certified for the area in which they are located.

Provision shall be made for switching off the outdoor area lighting, including street lighting from plant control room. The switch shall be lockable type.

Photometer (Luxmcter):

This is the common instrument to measure the intensity of illumination. It works on the principle that if equal illumination is produced on similar surfaces illuminated normally by two light surfaces, the ratio of their intensities equals the square of the ratio of their distances from the surfaces.



Photoelectric photometer is a device in which the light is measured by the current from a photo-electric cell. One such instrument is the luxmeter which is a portable photometer operating on the contrast principle and employing a variable aperture. To take a measurement at a given point, it is enough to expose the photo-cell to the light flux in the plane parallel to the work place and take the reading on the scale. A digital lux meter is shown in the figure.

Operating instructions include (1) Zero adjustment to set the pointer at zero position. (2) Inserting lumidisc into the light receptor. (3) Setting of lumidisc for ordinary measurement (0-5000 lux), high level measurement (5000 - 50,000 lux) or low level measurement (0 - 1000 lux).

Measured values are to be corrected by multiplying by the correction factor.

7 EFFECTS OF COLOUR ON SAFETY

What is more perceived? Colour or light? What the eyes see is colour and colour contrast, rather than light.

Lighting and colour are complementary and their effects are interdependent. Therefore, they are considered together in this Chapter.

No lighting scheme can be fully effective unless supplemented by well chosen and well maintained coloured surfaces.

7.1 Need of Colours :

Environments for work, play or relaxation have to be created and maintained. The colour and lighting influence vision and contribute to ' the wellbeing, morale, attitudes, housekeeping, quality, productivity, health and safety. In industry colours are used to :

1. Improve lighting conditions.
2. Decorate the environment.
3. Increase efficiency and productivity.

4. Improve quality of workmanship and normal skill.
5. Improve labour morale and interest in work.
6. Reduce accidents and increase safety.
7. Reduce 'rejects'.
8. Reduce absenteeism.
9. Raise standard of good housekeeping..
10. Improve building and machinery maintenance.
11. Reduce hidden costs of dull and gloomy atmosphere, and
12. Improve overall psychological and physiological effects on workers for better work performance.

7.2 Reflection Factors (LRV) :

A surface reflects light. The amount of light reflected will depend on the colour scheme of the surface. Pure white will reflect 100% and pure black 0% of light falling on them and reflections factor of other colours will fall in between. The recommended reflection factors, also known as light reflectance value (LRV), for interiors are :

Part	Colour	LRV
Ceiling	White	80-90%
Walls	Light colour	50-75%
Furniture, equipment, machinery, desk etc.	Light to medium colours	30-50%
Floors	Medium to dark colours	15-30%

Light reflectance values (LRV) of some colours are as follows :

Colour	Percentage of reflected light
White	85 to 90
Yellow	Light 75 medium 65
Grey	Light 75 medium 55 dark 30
Green	Light 65 medium 52 dark 7
Blue	Light 55 medium 35 dark 8
Ivory	Light 77 over green or white stippled 40
Cream	Light 66
Buff	Light 56
Brown	Dark 10

Appropriate colour should be selected from above two tables which conclude that ceilings and walls should have light colours for more reflection and floors, furniture and equipment should have medium to dark colours for less reflection. Colour can be used as a factor to reflect light to increase it.

7.3 Colour Code and Safety :

7.3.1 Indian Standards :

IS to be followed are : Code of practice for safety colours and safety signs 9457, Pipelines, identification, colour code 2379, Standard colours for building and decorative finishes 1650, pipelines in thermal power plants 9404, Identification for canisters and cartridges 8318 and Gas cylinders and related medical equipment 3933.

7.3.2 Colours to Identify Hazards :

Colour coding is most desirable and useful for safety purposes. Standard colours are used to identify hazards as follows :

Red	-	Fire protection, prohibition, danger, emergency stops on machines, red cross on medical facilities.
Yellow	-	Risk, danger or caution, hazards of slipping, falling, striking etc., flammable liquid storage, yellow band on safety cans, material handling equipment viz. lift trucks, cranes, crane hooks, caution, transport equipment, obstructions, change in floor level, stair nosing etc.
Green	-	Safety equipment not identified elsewhere, safety board, safe condition.
Blue	-	Warning and information signs, bulletin boards, rail road uses. It indicates safety colour only if used with a circular sign.
Orange	-	Dangerous parts of machines or energized equipment such as exposed edges of cutting devices, inside of movable guards, enclosure doors, transmission guards, electric installations.
Purple	-	Radiation Hazards
Black & White	-	Housekeeping and traffic markings. Also used as contrast colours.

White is a contrast colour for red, green and blue. Black is a contrast colour for yellow.

The piping in a plant may carry harmless or hazardous contents. Therefore it is highly desirable to identify them. Some standard colour coding is as follows:

Content in the piping	Colour
Flammable or water for fire protection	Red
Dangerous (hazardous chemical)	Yellow
Safe (water, air)	Green
Protective material (inert gas)	Blue

The proper colour may be applied to the entire length of the pipe or in bands 20-25 cm wide near valves, pumps and at repeated intervals along the line. The name of the specific material should be stencilled in black at readily visible locations such as valves and pumps. Piping less than 3/4 inch diameter is identified by enamel on metal tags. Anti-resistant colours should be used where acids and other chemicals may affect the paints.

Following colour coding is also useful in identifying pipelines (IS:2379):

S. No.	Material	Colour
1.	Water	Sea green
2.	Steam	Aluminum, IS 2339
3.	Air	Sky blue
4.	Acids	Dark violet
5.	Alkalis	Smoke grey
6.	Gases	Canary Yellow
7.	Hydrocarbons/ organic compounds	Dark admirality grey
8.	Mineral, vegetable and animal oils, combustible liduids.	Light Brown
9.	Other liquids / gases which do not need identification	Black

Entire length or a portion, more than 30 cm, of a pipeline should be painted so that it should not be mistaken for a colour band. The colour bands are superimposed on the ground colour, applied at start, near valves, joints, bends and end points. For a longer pipe, interval may be 50 m. Minimum width of colour band should be as under :

See Part 8.4 & 13.1(4) of Chapter-18 for colours of gas cylinders and pipe lines.

7.3.3 Accident Prevention Signs :

Accident prevention signs arc most widely used safety measures in industry. Their uniformity in the colour and design of sign are essential. Employees may be unable to read English or may be colour-blind and yet react correctly to standard sign. Following colours are normally used for signs :-

Sign	Colour
Danger Immediate and grave danger or peril.	Red oval in top panel; back or red lettering in lower panel.
Caution Against lesser hazards.	Yellow background colours; black lettering.
General Safety	Green background on upper panel; black or green lettering on lower panel.
Fire and Emergency	White letter on red background. Optional for lower panel; red on white background.
Information	Blue for bulletin boards.
In-plant Vehicle Traffic	Standard highway signs.
Exit Marking	See Life Safety Code, NFPA 101, Section 5-10.

Different types of Accident prevention signs are shown in fig. 9.1. See Fig. 18.1 in Chapter 18 also.

7.3.4 Painting of Plant and Machinery :

No lighting scheme can be fully effective unless well-chosen (and well-maintained) finishes are provided on main interior surfaces such as ceilings, walls, plant and equipment. The main object is to use colours which will reflect rather than absorb light. Diffused light thrown back in this way can contribute substantially to the total illumination on the work. It also improves the quality of the lighting by softening shadows and minimising harsh contrasts in the field of view, thus contributing to visual comfort and efficiency.

Because of full reflection of light, to paint the plant and everything by white colour is not advisable, because 'only white' .premises and equipment cause fatigue and boredom and are no incentive for active or creative work if there is no combination of other colours. Any extreme should also be avoided.

For ceilings, the reflection factor should be at least 75% which means white or near-white. A matt finish is preferable.. Aluminium paint is not recommended.

Walls are best finished in light pastel colours in the 50-75% range, except in the case of very brightly lit walls (e.g. those adjacent to a large window) which may need toning down to 40% or less to prevent them from becoming too glaring. Conversely, walls containing windows (but which receive no direct light themselves) cannot often be painted white with advantage.

Furniture should preferably have a reflection factor of at least 20%, and the modern blond (pale yellow) wood finishes and light grey paints for steel cabinets are preferred to the old-fashioned dark stained wood and dull olive green finishes. On desk and table tops which form a background to the work, it is important to guard against distracting reflections.

Floors should not be too dark. Practical considerations usually govern the nature of the floor finish, but 20-25% or so is. generally a satisfactory figure. Floor finishes which are very much lighter than this should be treated with caution since they can sometimes cause glare (e.g. particularly well-lit office interiors).

A well painted machine inspires feeling of personal pride and proper maintenance is encouraged. Under the General Code of Practice for Machine Guarding it has been provided that:

Colour schemes for machines be so selected as to cause least visual disturbance to the operator. Colour schemes should provide quite finishes of medium reflectance and should separate critical from non-critical areas of the machine. Critical 'areas are those which might constitute danger points or which need to be instantly visible. These should be painted in local colours i.e. colours which command attention (Red, Orange, Yellow). Non-critical areas are those which should be kept in the background. These should be painted in "Static" colours (Cream, Stone Grey, Pale Green, Pale Blue). Control areas should be painted in suitable colour to provide a neutral background for coloured indicator plates.

Guards should be regarded as part of the machine and should be painted in the same colour as the colour of the machine. Colouring recessed surface of machines with lighter shade than used for the outer surfaces help to minimise the effect of shadows on the inner surfaces (Example : Static grey for outer surfaces, static stone for recessed surfaces).

Identification colours on machines should be reserved for things which really matter, such as stop buttons and other safety tripping devices which must be found quickly in an emergency. "Safety colours" must also be used with great restraint. Dangerous moving parts should be guarded, not coloured, and when guarding is impossible, colour should be used to highlight the actual hazard and not merely as a general warning.

For paints IS : 5 and for building and decorative finishes IS : SP 1650 are relevant.

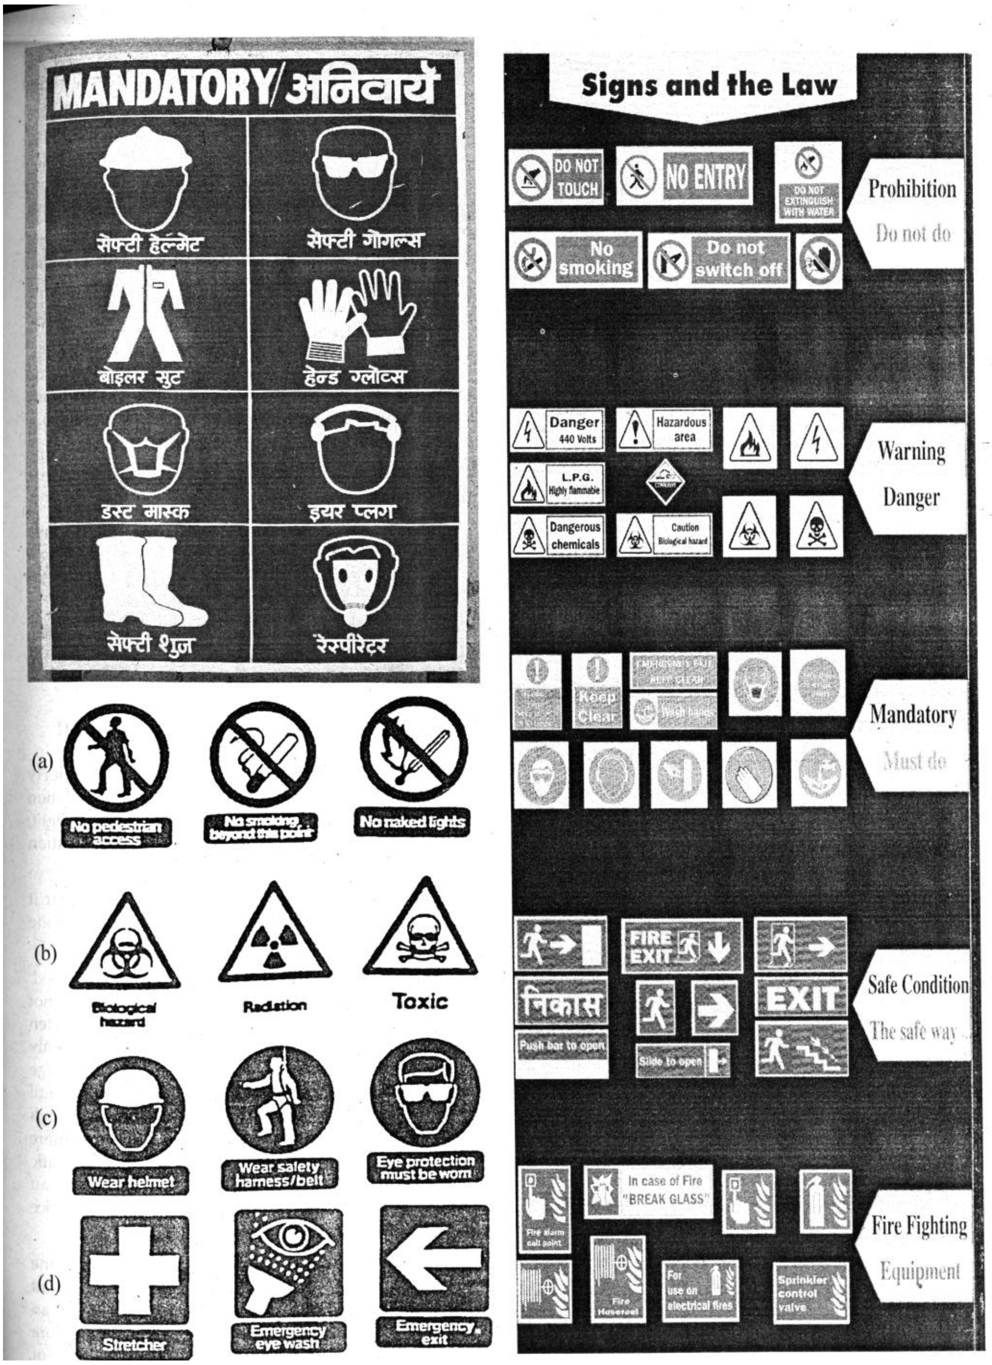


Fig. 9.1 Accident Prevention Signs : (a) Prohibitory (b) Warning (c) Mandatory (Legal) (d) Safe Condition

7.4 Psychological Effects of Colour :

They are as follows :

Colour & other parameter	Psychological Effects
Red	Stimulates, activates, energises
Yellow	Bright, Gray, Fresh like sunshine
Orange	Tension producing
Light Green Light Blue	Relaxed feeling, improve morale
Purple	Feeling of depression

White	Stimulating if it is used with warm colours
Black Size	Not depressing if it is used with other colours Green and Blue objects look larger than Yellow and Red
Space	Green and Blue surfaces record. Red and Yellow come forward.
Temperature	Red and Yellow give warm feeling. Blue and Green give cool feeling.
Weight	Bright colours make objects look lighter.

Red, orange and yellow (light) are warm colours. Blue, turquoise and green are cool colours. Off-whites and pastel tints are light colours. Black, grey and deep tones are dark colours and red, yellow, yellow green, orange and red-orange are considered bright colours.

Warm colours may be used to obtain activation and relaxation effects i.e. energy input. Cool colours are aid to energy output. Bright colours give an impression of useful place and lightness and produce calm and peaceful effect. Dark colours may have a cheerless and depressing effect.

In selecting colours following guideline is useful -

1. Natural white or light colours are safe and render all colour shades in true proportions.

2. Cool colours on objects give good effect. Therefore they are called safe object colours.

3. Bright colours should 'be preferred as background colours. More saturated richer colours should be preferred for objects. The sensation of colour of an object depends on the colour of the background.

4. Sources emitting warm colour of light, render warm colours of objects. The proportion of short-wave radiation makes cold colours ineffective.

5. Yellow seen against a black background will be luminous but will loose its luminosity when seen against white. This effect (simultaneous contrast) is true with all colours and shades.

6. When seen against black, every colour becomes brighter and against white paler. This is called successive contrast.

7. Colours can affect their background also (Bezoll's effect).

These rules emphasise importance of and interaction between light and colour. The appropriate light has to be chosen with colour and vice versa.

While designing colour schemes for plant and equipment, these factors are to be taken into consideration.

This discussion concludes t1iat the question of colour may not just be left to the painter, nor the question of light to the electrician. Scientific knowledge of combined effects of lighting and colour should be properly utilised.

Colour liking may change with time and fashion but safety aspect should not be forgotten.

8 MAINTENANCE FOR LIGHTING AND COLOUR

Unless a lighting installation is properly maintained, lamp depreciation and dirt accumulation on the fittings will cause an increasing loss of light; in some circumstances this can cut the illumination level by half in the period of only a few months.

When choosing equipment, make sure that it will be easy to clean and re-lamp, and also provide safe and ready means of access to the units.

Cleaning schedules should be carefully planned. Fittings should be cleaned at regular intervals and not just when a lamp fails. The need .for this is often overlooked because dirt collects so slowly and evenly that a deposit which may be absorbing a large proportion of the light is often difficult to detect until it is disturbed. Cleaning should be done often enough to prevent the illumination level from dropping more than about 20-30% during the interval. A systematic check with a light-meter at several fixed points in an installation is one way of deciding how often to service it.

Lamp Replacement should also be done systematically, and it is not always advisable to wait until they actually fail to light. The output of an incandescent lamp does not drop a great deal before it finally burns out; but this is not necessarily true of the fluorescent type, which may continue to strike Long after the light output has dropped to a very low figure.

Group replacement of all the lamps together at some predetermined time is often favoured for large retaliation in which many units are in use for approximately the same number of hours each day This group replacement takes place after the installation has burned for a fixed number of hours, or after some fixed proportion (say 20%) of the lamps has failed.

19. Choice of colour for plant and machinery.
20. Psychological effects of colour.
21. Need of maintenance for lighting & colour.
22. Colours and signs for accident prevention.
23. Different ' methods to derive maximum advantage of natural lighting in a factory building.

2. Write Short Notes on :

1. Sight and light.
2. Studies and results of lighting effect.
3. Light loss factors and reasons of light losses.
4. Adequate illumination.
5. Glare OR Shadow.
6. Uniform lighting
7. Colour effect
8. Flicker and stroboscopic effect
9. Day lighting
10. Artificial lighting and their types
11. Types of light sources or lamps (tubes)
12. Types of lighting fittings
13. Types of lighting installations.
14. Colour rendering index.
15. Illuminance ranges
16. Methods of calculation of artificial lighting
17. Photo (lux) meter.
18. Colour and light reflection factors or Light Reflectance Values (LRV)
19. Colours for accident prevention signs.
20. Colour scheme for machines
21. Cleaning scheme for lighting fittings
22. Statutory provisions for lighting in factories.
23. Need to allow upward light toward roof or ceiling

3. Comment on following stating whether it is true or not:

1. Eyes, sight and light are interdependent.
2. Good lighting increases safety and bad lighting decreases it.
3. Contrast should be appropriate.
4. Illumination level (standard) cannot be fixed for all persons and places.
5. Colour has no effect on lighting.
6. Lighting and colour are complementary.

7. Guards should have different colour than that of the machine.
8. Ceiling, floor and wall should have different colours.
9. Colours have no effect no mind.
10. Group replacement of lamps has advantages.
11. Good artificial lighting improves work performance and safety.
12. Indian Standards mentioned in this Chapter.

CHAPTER – 10

Ventilation and Heat Control

THEME

1. PURPOSE & EFFECTS OF VENTILATION AND HEAT CONTROL

Clean, fresh and uncontaminated air is a basic need of life. Industry has many pollutants which contaminate air and heat stress is generated due to hot processes. Well designed and effective ventilation provides solution to these problems.

1.1 Purpose of Ventilation and Heat Control:

The need or purpose of ventilation and heat control are summarised here as follows :

1. Air is life and fresh air is the first need for survival of living creatures. Absence of air brings death within a few minutes. Life without breathing is not possible and the clean air is needed for the whole life- for breathing and functioning of human body. Therefore good ventilation giving sufficient fresh air is the permanent requirement.

2. Human body cannot tolerate excessive temperature. Heat stresses produced by very hot or cold exposures cause adverse effects on health and safety of work people. Therefore

environmental temperature control is also permanently needed for well functioning of human body. Ventilation helps in removing excessive temperature.

3. Heavy physical work or heavy work load causes heat stress and strain and increase metabolic heat, body temperature, sweating, heart rate etc. To maintain (control) body temperature, ventilation is necessary. See Part 5.1.

4. Carbon dioxide is continuously exhausted by all human beings. Much more contaminants are added by manufacturing processes to pollute air. Therefore cleaning of air and supply of fresh air with sufficient oxygen are also necessary. This is possible by good ventilation and pollution control techniques only.

5. Where due to weather or atmospheric conditions or process parameters, excessive temperature is unbearable or uncomfortable, air conditioning or HVAC systems are also necessary. Conversely where air heating is necessary as in case of excessive cold climate, it must be provided.

6. Basic functions of ventilation are to (a) maintain the oxygen content of the air and to prevent CO, concentrations from rising (b) prevent or removal of body odours (c) prevent harmful concentration of aerosols and air-borne contaminants and (d) maintain reasonable conditions of thermal limits for comfort and efficiency which result in decreased heat stress, increased productivity, reduced accident rates (hot conditions induce unsafe acts) and adverse health effects (interaction with other hazards), higher level of job satisfaction, reduced absenteeism, improved attitudes, reduced downtime for hot vessels and compliance of required standards.

7. While designing industrial buildings care must be taken to provide good ventilation for dilution of inside air to prevent vitiation by causes, such as body odours, to remove process released contaminants and heat exposures to maintain satisfactory thermal environments, to maintain heat balance of body and to prevent acute discomfort and injury to the health of the workers. If natural ventilation is not sufficient for these purposes, mechanical ventilation, cooling system or other techniques must be employed to achieve satisfactory results.

8. As explained in subsequent part 5.1 & 5.2 of this Chapter, the basic need for ventilation is to maintain the body heat balance equation by controlling air and surrounding temperature, humidity and air velocity. Therefore supply, well distribution and maintenance of fresh air throughout the factory are utmost necessary to maintain comfortable working conditions as expected by sections 13 to 15 of our Factories Act.

Thus main purpose of ventilation is to remove heat 'and contaminants from air in residential or industrial building and to supply or regulate fresh and cool (or hot) air for the comfort of the occupants or workers.

The term industrial ventilation refers to ventilation systems for the industrial use. Main four functions of ventilation are (1) to supply sufficient fresh air (2) to distribute it throughout the work room (3) to remove polluted and hot air and (4) to maintain comfortable working conditions.

Mainly ventilation is employed for human comfort and therefore called comfort ventilation or air-conditioning. It is also employed for process control by mechanical ventilation (process ventilation) as explained in Part 7.3.2.

The quantity and quality of air required for ventilation depend upon -

1. Rates of heat generation in the room.

2. Rates of contaminants (gas, vapour, dust) generation in the room.
3. Rates of dispersion of heat & contaminant.
4. Rates of dilution and/or removal that may be achieved by ventilation.
5. Electric fittings for ventilation system in flammable/explosive area should be flameproof and of the approved type.

1.2 Effects of Good and Bad Ventilation:

From above discussion, effects of good and bad (poor) ventilation are inferred as tinder -

Effects of good ventilation are:

1. Availability of sufficient fresh air for breathing or life.
2. Removing oxygen deficiency from a confined space.
3. Removal or dilution of carbon dioxide and other air pollutions.
4. Decrease in environmental heat or temperature.
5. Increase in air changes per hour as per statutory requirement.
6. Maintaining metabolic body temperature or heat balance.
7. Removal of air contaminants (dust, gas, fumes, mist etc) from work room.
8. Maintaining room temperature for comfort
9. Providing desired air conditioning (cooling or heating).
10. Removal of body odour and bad smell from the room.
11. After heavy physical work, evaporating body sweating and making the body cool.
12. Decreasing discomfort and distress.
13. Maintaining efficiency of work.
14. Decreasing chances of accidents and maintaining safety and productivity.
15. Providing better job satisfaction and good attitudes.
16. Increasing cooling rate of hot vessels or hot substances.
17. To maintain overall comfortable working conditions and
18. To help compliance of statutory provisions and standards.

Effects of bad ventilation are opposite to above i.e. non availability of fresh air for life, insufficient air changes, no cooling effect, discomfort, body stress and strain, no removal of air contaminants, body odour, bad smell etc, increasing chances of accidents, lowering efficiency and productivity, no job satisfaction, more time for cooling of hot vessel and substances and violation of statutory provisions etc. See Fig. 10.1 to 10.4.

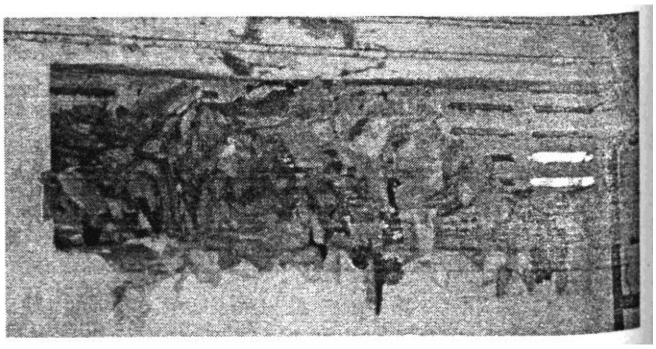

Fig. 10.1 Ventilator is badly obstructed

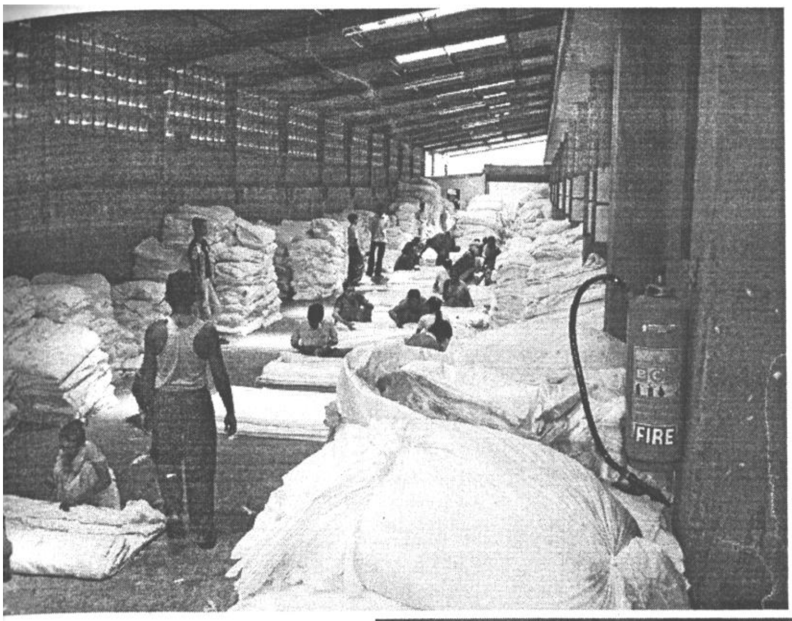
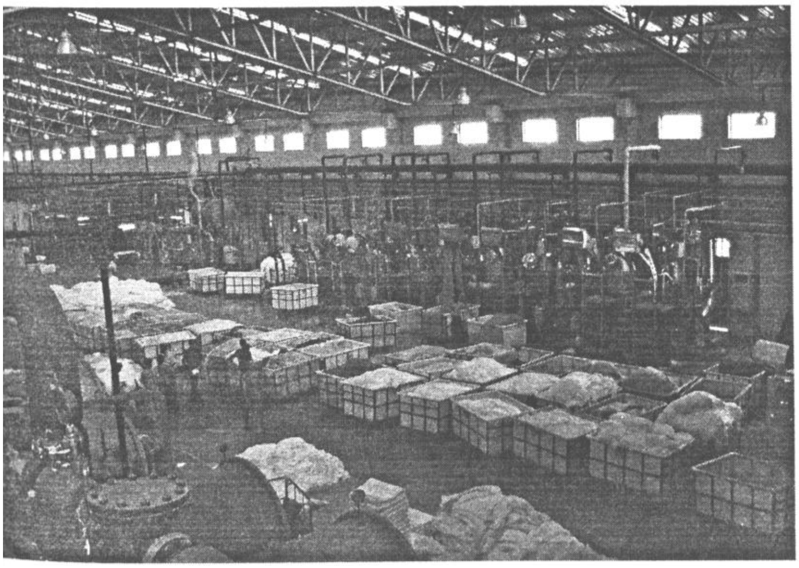


← **Fig. 10.2** Hazard - No Windows for passage working

Fig. 10.3 Hazard - No Windows and Closed Ventilators →



← **Fig. 10.4** Hazard - No Windows and fixed glass Ventilators. Poor Ventilation.

2 STATUTORY PROVISIONS

Sec. 13 of the Factories Act requires effective, suitable and adequate ventilation in every factory, by the circulation of fresh air and such a temperature to provide comfort and prevent health injury to workers. It also requires well designed walls, roofs and insulation of hot parts to reduce the excessive temperature.

Sec. 14 requires local exhaust ventilation at the source of dust, fume or other impurity, with the enclosure (hood or cover) on such source (point of origin), to prevent inhalation and accumulation in the workroom, of such injurious or offensive dust and fume.

Sec.l5 provides for artificial humidification and rules 19 to 29, GFR, prescribe dry and wet bulb temperatures, details of hygrometer and manner of introducing steam.

Sec. 16 calls for 'a minimum 14.2 m" (height 4.2 m max.) of breathing space per worker.

Sec.36 and 37 prescribe for venting dangerous gases from a confined space and safety measures including work permit, self breathing apparatus and safety belt before allowing entry to such confined space.

Rule ISA of the Gujarat Factories Rules (GFR) prescribes workroom temperature 30 "C (86°F) at a height of 1.5 mt, air movement of at least 30 m/min with 6 air changes per hour, a schedule for dry and wet bulb temperatures and ventilating area more than 15% of the floor area. See Part 6.4 for details.

Rule 102 (GFR, 1963) and many Schedules there under require effective local exhaust ventilation on dust/fume/gas generating processes and their test report in Form No. 26A.

New rule 12B prescribes Form No.37 for work environment monitoring. Rule 68G for ovens and dryers and new schedules 2,11,17,19,25 and 26 u/r 102 GFR, also require appropriate local exhaust ventilation for dust, gases etc.

3 INDIAN STANDARDS

Some IS are: Ventilation - industrial 3103, natural, of residential buildings 3362, in petrochemical plants and refineries 12332, mechanical on ships 5858, tubing, PVC 3768., Specification for roof extractor units 3963. Ventilation ducting, metal duct '655, Vinyl coated, semi-rigid 12814., Ventilator - aluminium 1948, cabin 3941, chain 3828, cowl 3271, frames timber 4021, gooseneck, welded, pipe 3274, metal, code of fixing and glazing 1081, mushroom 3279. Venturi meters for fluid flow 4477., Specification for propeller type AC ventilating fans 2312., Electro-heat installation 9080. Air conditioning safety code 659. Mechanical refrigeration, safety code 660, Air pollution - glossary of terms 4167. methods of measurement 5182 (part 1 to 20), in petroleum refineries 10179, Ambient air quality limits - units for measurement 9620, from fertiliser industries 8635, from petroleum refineries • 8636, from cement plants 10693, from mmf plants 9233 from diesel vehicles 8118, for CO from spark ignition engines 9057., Ringelmann smoke charts 9078 micrometeorological techniques 8829.

The use of first mentioned IS:3103, Code of practice for industrial ventilation is strongly recommended for engineers, as it provides details of safe design, installation, operation, testing and maintenance of ventilating systems regarding general and dilution ventilation for industrial process and measures of heat control in such process. It explains 23 definitions also.

4 THERMAL ENVIRONMENT AND ITS MEASUREMENTS

Before controlling temperature, humidity and air movement it is necessary to measure their adequacy. Subsequent measurement is also necessary for the, satisfaction that whether they are properly controlled or not. Some methods and equipment are explained below for this purpose.

4.1 Temperature Measurement:

The mean radiant temperature of the surroundings is calculated (not measured) from the values of dry bulb air temperature, the glob temperature and the air velocity.

Thermometers placed at the height 1.5 m above floor level and not within I m from any heating device are used to measure the air temperature. For precise measurement and recording of temperature, thermographs are used. Recording period may be as per requirement.

The Glob thermometer is a black-painted (mat), hollow copper sphere, 15 cm in diameter, into which a thermometer is inserted. It therefore measures temperatures which include radiant heat effects. It is preferable to a dry-bulb thermometer. Rule 18A(1) of the • Gujarat Factories Rules 1963 provides for a glob thermometer of 15 cm dia to be kept in the environment for not less than 20 minutes and consideration of the temperature recorded by it, if it exceeds the dry-bulb temperature of the air.

The glob is suspended at the point of measurement, about 1.2 m above the ground, not contacting any solid. Thus the globe gains heat by radiation and loses by convection (not conduction). When thermal equilibrium is reached (by @25 minutes)/ the reading in the thermometer gives the globe temperature tg.

4.2 Humidity Measurement:

Psychrometers or wet and dry bulb hygrometers are used to measure relative humidity of the air. **Hydrographs** are used for continuous recording of the air humidity where the humidity requirements are most stringent. The two temperatures of dry and wet bulbs are used with a psychometric table or chart to determine relative and absolute humidity, dew point and other conditions of an air-water mixture. The direct dial hygrometers are also available.

A whirling hygrometer (sling psychro-meter) is used to assess the ambient air temperature and humidity. The dry and wet bulb assembly is rotated at 60 rpm till the readings become steady. The reading of the dry bulb gives the ambient temperature while drop between dry and wet bulb temperature is an indication of relative humidity by using a psychometric chart.

4.3 Air Movement and Content Measurement:

For recommended values for air movement and air changes See Part 2 and 6.4. Values recommended by IS:3103 are as under -

Anemometers (Velometers) are used to measure the velocity of the air. The revolving - vane and the revolving - cup types are in common use. The Vane anemometer consists of eight vanes fixed on a hub at 45Q to the air stream and pivoted so as to rotate in a vertical plane. The speed of rotation is indicated on a dial calibrated to read air velocity from 0.3 to 5 m/s. 77ie Cup anemometer consists of four hemispherical cups carried on the ends of four radial arms pivoted so as to rotate in a horizontal plane. The speed of rotation is indicated on a dial graduated to read air velocity from I to 20 m/s. Velocities under 0.3 m/s are measured by means of a microanemometer or electrical thermal anemometer.

Kata thermometer designed by Leonard Hill in 1914 measures the cooling power of the air to cool skin surface, a power that is measured in terms of dry-bulb temperature, the radiation and the rate of air movement. The kata thermometer is an alcohol, liquid - in glass thermometer with a large bulb and an upper reservoir. There are two marks on the stem. It is cheap but fragile and useful for low air velocities below 0.25 "V s (50 fpm). The bulb is warmed by a warm water so that the alcohol fills up the whole thermometer (up to 40 "C). The thermometer is then carefully dried and placed at the sampling point.

The cooling time is measured .by a stopwatch. Then air velocity is calculated by using the values of cooling time, air temperature and instrument factor.

Swinging van anemometer. Hot wire anemometer (anemotherm air. meter), Alnor thermo-anemometer, Mechanical anemometer. Thermistor Bead anemometer, Heated thermocouple anemometer and Rotating vane anemometer of clock type or electronic direct-reading type are also used in industrial hygiene to measure the air velocity.

Pressure tubes are used to measure both pressure (total and static) and velocity of the air in air ducts. The dynamic (velocity) pressure is determined as the difference between the total and the static pressures. The air velocity in air ducts can be measured with a Pressure head device (static and pilot tube connected with differential pressure U-gauge).

Indication tube or Gas detection tube is used to measure contents of air contaminants such as toxic vapours and gases viz. Cl_2, CO, SO_2, NO_2, PH_2 ethanol etc. A common type is hermetically sealed glass tube about 4 to 7 mm wide and 100 mm long containing a filler (crushed silica gel, glass or porcelain crumbs) treated with solutions of various reagents. The tube is kept into intimate contact of the air to be analysed. By pump-strokes air sample is drawn in. The concentration of the impurity can be read on a scale by a length or rate of change in colour of the filler material that has completed reaction.

Air purity can be measured by air or gas analysers of various designs. Direct techniques of gas analysis-spectrometry, electrical-chemical and optical methods permit automatic and continuous air analysis. In air sampling method the samples collected by air sampler pumps, are analysed in a laboratory to get accurate measurement.

Indoor air quality monitors are direct reading instruments for gaseous sampling.

Dust contents in the workroom are determined by passing a measured\quantity of air through filters during a particular time and calculating the dust mass collected. Methods to measure character and size of dust particles are also available.

Following three parameters should be measured to assess the performance of ventilating systems :

1. Capture velocity.
2. Air volume flow rates in various places in the system.
3. The pressure losses across filters and other fittings and pressures developed by fans.

The design value of these items is specified by the manufacturer of the equipment. Therefore instruments and devices are required to

1. Measure air velocities in various places.
2. Measure air pressure differences.
3. Trace and visualise airflow patterns.

As stated earlier, air velocity can be measure(by vane anemometers or heated head (hot wire or thermostat) air meters. Anemometers are most suitable for open area (e.g. large hood and tunnel). While heated head air meters are more suitable for inserting into duct or slot but it is not suitable where flammable gas/vapour may be present. Average velocity (measured) multiplied by the area of the opening gives the volume flow rate.

Pilot-static tube is used to measure air velocity above 3 m/s. If <air flow pressure P (N/m2 or Pa) is known, considering air density d=1.2 kg/m3 for most ventilation situations, the air velocity V (m/s) is give by-

$$V = \sqrt{\frac{2P}{d}} \quad \text{or} \quad P = \frac{1}{2} dV^2$$

Pilot static tubes are thin and can be easily inserted into ducting. All velocity meters should be placed parallel to the air stream and calibrated from time to time.

Pressure difference in air can be measured by a manometer or U-tube gauges filled with water or paraffin. Diaphragm pressure gauges are also available.

Air flow patterns can be detected by smoke tubes which produce a plume of smoke when air is puffed through them. For airborne particles, dust lamp is used to see moving particles in a light beam.

See also Form No. 26A, GFR, for 'Test Report of Dust Extraction System'.

5 PHYSIOLOGY OF HEAT REGULATION

Heat effects on human body and their control measures are mentioned below. The other measures are described separately in parts 7 & 8 of this Chapter.

For physiology see Part 2 of Chapter-24.

5.1 Heat Stress and Thermo Regulation:

There are two types of animals - Poikilotherms whose body temperature equals the environmental temperature and Homeotherms whose body temperature fluctuates within a small range to maintain the temperature stability for metabolic functions. Human body maintains the temperature @ 36 to 39.5° C (96.8 to 103.1" F). To maintain this small range of thermal stability against too high or too low environmental temperatures, the homeotherms (which includes us) have to undergo some stresses which adversely affect performance and efficiency.

Heat Stress is the burden or load of heat that must be dissipated if the body is to remain in thermal equilibrium and is represented by the sum of metabolic heat (physical work) and environmental heat load. The environmental factors are governed by the air temperature, humidity, air movement and the temperature of surrounding (radiant heat exchange).

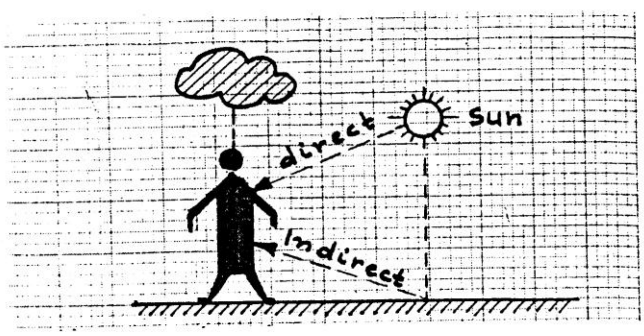


Fig. 10.5 Human body exposed to Sun a main source of heat

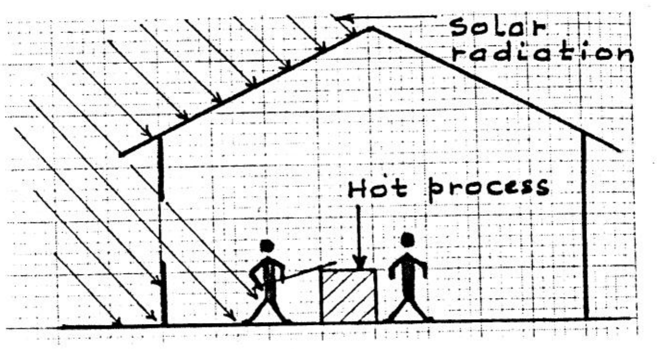

Fig. 10.6 Sources of heat - Solar radiation and -hot processes

Physical work contributes to the total heat stress of the job by producing metabolic heat in the body in proportion to the intensity of the work.

Clothing affects the heat stress. Cotton clothing is most comfortable as it soon absorbs sweating and dissipates heat. Synthetic clothing, though looks good, adds to sweating and increases heat stress.
Heat Stress of any given work environment is .considered as the combination of both climatic and non-climatic factors leading to heat gain by the body by convection and radiation and/or limiting heat dissipation from the body.

Climatic factors are : air temperature, humidity, radiant temperature and air movement.

Non-climatic (personal) factors are : metabolic workload (degree of physical work), clothing, age, sex, body build, acclimatisation, physical fitness and ethnic differences.

Heat Strain is the physiological or pathological change (response) resulting from heat stress viz. rise in body temperature, sweating, heart rate etc. The severity of strain depends on prevailing stress, age, physical fitness, degree of acclimatisation and dehydration of the worker. When the strain becomes excessive, discomfort or distress is felt. Acclimatisation helps to tolerate heat stress.

Heat Balance Equation:

$H = M - E \pm C \pm D \pm R - P - U$

Where

H	=	Amount of heat gain or loss by the tissues of the body. If the body maintains thermal equilibrium S = 0
M	=	Metabolic heat production. It depends on the rate of metabolism.
F	=	Evaporative heat loss. It partly depends on the sweating rate and partly on the climatic conditions, especially water-vapour tension and humidity.
C	=	Convective heat gain or loss } depends
D	=	Conductive heat gain or loss } on the
R	=	Radiant heat gain or loss } climatic } condition
P	=	Heat expanded in physical exertion
U	=	Heat loss due to respiration, exertion, urination etc.

A hot environment will increase heat gains by radiation, convection or conduction. Humidity retards heat loss from the body by evaporation. The body will attempt to balance any heat gain by perspiring to increase cooling by evaporation. If the loss of heat does not balance the gain, the body will suffer.

The rate of metabolism (metabolic rate) for a' sedentary i.e. seated adult is about 100 Kcal/hr but it increases in heavy work up to 1000 Kcal/hr. Heat balance equation suggests the factors determining heat stress as air temperature, air velocity, humidity, temperature of surroundings, degree of activity and clothing worn.

Therefore it should be the basic aim of any ventilating system to

1. Keep the air temperature in the room low enough to dissipate body heat by convection.
2. Prevent excessive humidity to help body heat loss by evaporation and
3. Regulate the air movement to help body heat loss by rapid evaporation.

Metabolic heat production (Metabolic rate) : It is the amount of heat produced in the body by way of metabolism which varies depending upon the level of activity.

Activity (Category)	Heat production (Metabolic rate) Kcal/hr
Basal condition	60-120
Light physical work	120-220
Moderately heavy physical work	220-320
Heavy physical work	320-420
Very Heavy Physical work	420-540

Convective heat gain or loss : Body gains or looses heat by convection depending upon the gradient between the skin and air temperature. It is modified by air movement. For a nude man, the following equation can be used to calculate the heat exchange by convection.

$$H = 0.5\ V\ (ts-ta\ )$$

Where H = amount of heat loss/gain in Kcal/m^2 of body surface area/hr,

V = air speed in ft/min,
t_s = skin temp. in ^{0}C and
t = air temp in ^{0}C.

Radiant heat gain or loss : Depending upon the level of radiant temperature (t_r) of the surrounding environment over that of the skin temperature (t_s) the body will gain or lose heat by radiation. The following equation represents heat exchange by radiation.

$$H_r\ (Kcal/m^2/hr) = 5.7\ (t_s - t_r)$$

Evaporative heat loss : Sweat produced on to the surface of the skin evaporates, when the vapour pressure on the skin is higher than the vapour pressure of the surrounding environment. Air movement enhances evaporative heat loss. By using the following equation, the heat loss due to evaporation can be worked out.

$$H_e = 1.4\ V\ 0.37\ (P_s - P_a)$$

Where

H_e = evaporative heat loss in Kcal/ m^2/hr,
V = air speed in ft/min,
P_s = vapour pressure of the skin and
P_a = vapour pressure of the air.

Factors affecting heat-balance of the body :

Heat-production is increased by combination of carbohydrates, fats and proteins. The factors are : Basal heat production (BMR) specific dynamic action of food (SDA), Higher BMR, Unconscious tensing of muscles, shivering and exercise.

Heat loss is increased by convection, radiation & evaporation. The factors are : Basal heat loss, increased air movement, increased radiating surface, increased insensible vaporisation, increased skin circulation, sweating, panting and decreased clothing.

5.2 Thermal Limits for Comfort and Efficiency :

The effect of atmospheric condition i.e. temperature, ventilation, humidity, radiant heat, greenhouse effect etc., upon worker's efficiency or susceptibility to accident is difficult to predict, because, it varies with person to person and one comfortable condition may be uncomfortable for others. Much variation from the body temperature 37°C (98.6° F) causes discomfort for the majority of factory workers doing light work. A dry-bulb temperature of 18°C (64° F) represents the most satisfactory condition and variations of 2 to 3 degrees from that seem to have little discomforting effect. In Indian atmosphere 20 to 30°C is the comfortable temperature for a variety of workers.

American Ventilating Engineering Association recommends the following ranges as the most acceptable:

	Place	**^{0}C**	**^{0}F**
1	Lecture Hall	16-18	61-64
2	Sleeping Rooms	12-15	54-59
3	Workshop (moderate activity)	16-18	61-64
4	Workshop (vigorous activity)	10-15	50-59
5	Bathrooms	20-22	68-72
6	Gymnasium	15.5	60

Some recommended upper limit values of comfortable temperature are as follows :

Consideration	Critical Effective Temp.	
	^{0}C	**^{0}F**
1. Safe tolerable limit for -		
(a) Light work	32	89.6
(b) Moderate work	29.5	85.1
(c) Heavy work	29	84.2
2. Prevention of steep fall in production	28.9	84
3. For efficient production	26.7	80
4. For thermal comfort in light / sendetary work	20-24.7	68-76.5

Effects on skin in contact with surfaces at different temperatures are also noted. Temperatures 160°F, 180°F and 212°F cause second degree burn on 60, 30 and 15 second contact respectively. 140°F gives pain due to tissue 'damage (burns) and temperature below 32°F also gives pain due to tissue damage (freezing). 120°F gives pain due to burning heat. 9U4°F gives warm or neutral feeling (physiological zero). 37 to 54°F gives cool effect and from 32°F and below gives pain due to freezing.

But the temperature alone is not a good indicator of comfortable conditions. In spite of above desirable level, discomfort may be caused because of frequent drafts (wind speeds), excessive moisture, undue dryness and high radiant heat. The recording and regulating of these factors and equating them with experiences of comfort, .and discomfort has been an old problem of safety engineers.

The effect of atmospheric conditions on output and accident rate has been demonstrated in a number of studies. The optimum temperature varies with the type of work that is performed and depends upon the state of health, age, clothing, diet and the ability of the employee to adapt himself to different climatic ' conditions.

Numerous studies have been reported showing a close relation between accident frequency and atmospheric conditions. One study of collieries workers indicates that at an average temperature of 16.5°C (62°F), the accident frequency and severity rates were minimum. Another study pointed out 21-23.5°C (70-74°F) temp. range to keep the accident rate minimum. One study of hourly accident rates inferred that the accidents were higher during the last hours of the day shift and the first hours of the night shifts.

Mental Work experiments of the New York ventilation commission demonstrated that such work maybe performed as effectively under humid (80%), hot 30°C (86"F) and stagnant air conditions as under optimum conditions of circulating air at 30°C (68°F) and 50% humidity. The influence of controlled ventilation on attitudes and labour turnover affects all types of workers and -a favourable attitude of workers toward the management is an indirect benefit which should not be overlooked.

Barometric pressure has little effect, whereas temperature and humidity have considerable effect on behaviour. Production was at its highest level when the temperature was 30°C (68°F) and the air was fresh and circulating. Using this as a base, it was noticed that stagnant air caused production to fall off® 9%. Relative humidity of 40-50% is desirable for comfort and hygiene. Humidity belmv 30% are undesirable as they may cause dehydration of mucous membranes of the nose and respiratory tracts.

Toxic effects of chemicals may be magnified when temperature is raised, because, toxicity of chemicals is known to increase due to temperature rise as follows :

	Chemical	Toxicity at	
		24 ^{0}C	35 ^{0}C
1	Carbon Tetrachloride	1	3.9
2	Carbon Monoxide	1	2.4
3	Amylnitrate	1	3
4	Lead	1	>1

Heat Disorders are noticed at higher temperatures. A man may collapse at core (body) temperature of 39.5°C (normal oral temp. 37°C). At about 40.6°C (105°F) the sweating mechanism fails and the core temperature rises sharply. When the temperature reaches 42 to 43.5°C (108 to 110°F) death occurs. The commonly disorders experienced by Indian workers are (1) Heat exhaustion and collapse (2) Water depletion, heat exhaustion and heat cramps (at times).

Accident rate in hot environment was double than that under comfortable climatic conditions. The contributing factor according to Stephen Altman (1976) was lowered physical performance.

Thus temperature exceeding thermal limits cause discomfort, annoyance, agony and frequency of errors and accidents ultimately resulting in poor productivity.

Other Factors affecting ability to withstand high temperatures are (1) Fatigue and lack of sleep (2) Worry, frustration and nervousness (3) Smoke from cigarettes, dust, gas etc. and (4) Disagreeable odour

5.3 Heat and Cold Stress and their Indices:

Attempts have been made in past to evaluate the total heat stress limits (Tolerance or Threshold limits) by integrating some climatic and non-climatic factors which affect heat exchange between the man and surrounding environment. Heat Stress Index (HSI) can be calculated or obtained from charts and takes into account clothing and work load. From it can be recommended duration of work and rest period. Some such indices are as follows :

(1) **Effective Temperature (ET) :** It is a sensory scale of warmth derived from the dry and wetbulb temperature (i.e. air temperature and humidity) and air velocity from standard nomogram. ET is not a temperature measurable with instruments. It is an index combining effects on a body of temperature, humidity and air movement. It is equivalent to the comfort a person generally feels (there may be exceptions) in a saturated atmosphere with the same dry bulb temperature and with a specific movement of air. A person remains equally comfortable under different conditions, provided the ET remains the same.

(2) **Corrected Effective Temperature (CET) :** It is a modified ET considering the radiant temperature measured by glob thermometer instead of drybulb temperature. It does not include metabolic heat.

Considering lower body weight of Indians, ET and CET proposed by the Central Labour Institute, Bombay are as follows :

Workload	Energy Expenditure Kcal/ hr.	ET or CET ^{0}C
Light	135	32
Medium	225	29.5
Heavy	315	29

(3) **Wet Bulb Globe Temperature (WBGT) :** It embraces in a single value the effect of radiation, ambient air temperature and humidity. It is the weighted value of the wet and dry bulb temperature and globe thermometer readings, calculated using temperature measurements alone thereby eliminating the need to measure air velocity.

For outdoors (exposure to sun light) :

$$WBGT = 0.2\ t_g + 0.1\ t_{db} + 0.7\ t_{wb}$$

For indoors (no direct exposure to sun light):

$$WBGT = 0.3\ t_{db} + 0.7\ t_{wb}$$

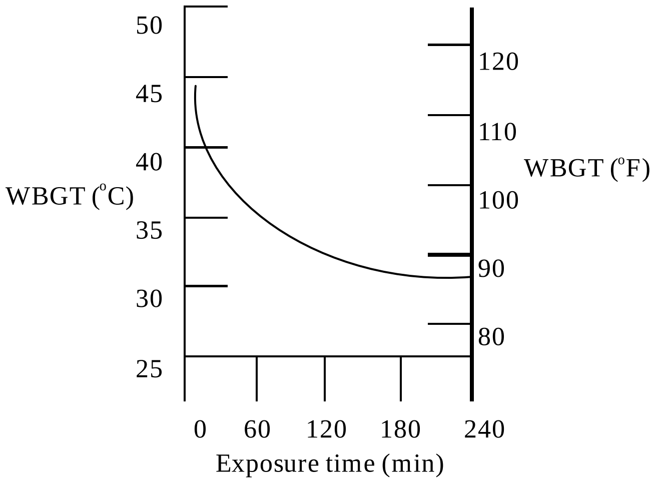
Where tg = Black Globe temperature,
tdb = Dry bulb (air) temperature and
twb = Wet bulb temperature

(°C) index is adopted by many countries to set up standards for work in hot environments. Its determination is simple and requires less expensive equipment.

It is necessary to determine the average exposure of a person over a long period of time when WBGT varied. A time-weighted average is given by : Average WBGT =

$$\frac{WBGT_1 \times t_1 + WBGT_2 \times t_2 + \ldots WBGTn \times tn}{t_1 + t_2 + \ldots tn}$$

Exposures should not exceed the values given in the following chart :



The graph shows the upper limits of exposure for feeling comfort.

Calculated time weighted or average WBGT can be compared with permissible (comfortable) level of WBGT values (°C) given in Table .10.1

This table is changed in 'ACGIH booklet 2007'. There the words ''TLV' and 'Activon Limit' are used for 'acclimatized' and 'unacclimatized' respectively. WBGT figures are slightly changed. For detail, it should be referred.

For non-cotton, non-woven clothing, overalls (double cloth) which disallow free air movements through fabric or does not absorb sweating '3 to 5' should be added to measured and calculated WBGT values which should be less then the values given in Table 10.1. These values (Table 10.1) are near the upper limit of the metabolic rate category. They are also called Screening Criteria for heat stress exposure. See Part 10 for worked examples.

(4) **Oxford Index** : This index of heat stress has been devised to assess the severity of hot humid conditions 'of the working places, particularly where the ventilation is poor. It is expressed by a simple weighting as follows :

$$WD = 0.15\ t_{db} + 0.85\ t_{wb}$$

Where WD == Weighted value, t_{db} and t_{wb} are dry and wet bulb temperature respectively. All units are in °C.

Table 10.1: WBGT -(heat stress) values in "C (ACGIH Booklet 2006.

Work demand	Acclimatized				Un-acclimatized			
	Light	Moderate	Heavy	Very heavy	Light	Moderate	Heavy	Very heavy

100% work	29.5	27.5	26		27.5	25	22.5	
75% work 25% rest	30.5	28.5	27.5		29	26.5	24.5	
50% work 50% rest	31.5	29.5	28.5	27.5	30	28	26.5	25
25% work 75% rest	32.5	31	30	29.5	31	29	28	26.5

(5) **Predicted Four Hourly Sweat Rate (P4SR):** This index is based on the assumption of the amount of sweat that would be prescribed by a physically fit and acclimatised young man in the condition under review over a period of four hours. It takes into account the metabolic level and type of clothing in addition to the climatic factors, unlike other indices mentioned earlier. But this has the drawback that cumbersome nomograms are .required which is not always practical.

(6) **Cold Stress and Wind Chill Index (WCI):** It refers to the cold environment and uses only dry bulb temperature and air velocity but takes into account the cooling effect of the wind.

In cold countries where environmental temperature goes below °C, cold stress (hypothermia or frostbite) is also possible. Body (core) temperature (rectal 37.6°C, Oral 37°C) should not fall below 35°C (95"F). Hands, feet and head are most likely to be affected by cold injury. Wind speed increases cold stress. As TLV body (core) temperature should not fall below 36°C (96.8"F).

Wind chill cooling rate is defined as heat loss from a body expressed in watts/m', which is a function of air temperature and velocity upon the exposed (area of) body. Higher wind speed and lower air temperature require higher insulation. value of the protective clothing. Exposure or working time of workers should also be reduced. Old and weak workers need such extra precaution.

Since the physical activity level on the shop floor will remain almost constant, we may make use of the simple indices like CET/ET or WBGT in our control programmes.

Heat Exposure Threshold Limit Values (USA) and Bolding Hatch Heat Stress Index (HSI) are other indices.

5.4 Health and Safety Problems in Hot and Cold Environment:

5.4.1. Problems in Hot Environment:

Types of health disorders caused by exposures to high heat are as under :

1. Skin disorders - prickly heat (miliaria rubra), skin cancer (rodent ulcer).
2. Systemic disorders - heat stroke (hyperpyrexia), heat exhaustion (circulatory deficiency, heat syncope), heat cramp (sweating deficiency), water deficiency, salt deficiency.
3. Psychoneurotic disorders - mild chronic heat fatigue, acute loss of emotional control.

These disorders can cause following effects

1. Heat or sun stroke due to excessive rise in core (body) temperature 'resulting from failure of thermo regulatory mechanism.
2. Heat Exhaustion due to loss of body fluid (with salt) in sweating.
3. Heat or muscle cramps due to profuse sweating and salt loss, drinking much water and failure to replace body's salt loss.
4. Fainting due to more blood in the skin and lower part of the body, less return to the heart for pumping to the brain.

5. Heat Rush or Prickly Heat likely to occur in hot and humid environment where sweat is not easily removed from the skin surface and sweat glands plugged.
6. Transient heat fatigue due to prolonged heat exposure.

Safety Problems are : Accidents due to sweating palms, dizziness, forging of safety glasses, contact with hot surface, molten metal, steam etc., and physical discomfort and fatigue.

Other safety problems due to increased temperatures are:

1. Increase in corrosion rate.
2. Increase in pressure in a confined space.
3. Decrease in reliability of electronic devices.
4. Decomposition of liquids generating contaminants that may plug orifices so equipment fails.
5. Burns to personnel and reduction in their efficiency.
6. Fire and explosion. Liquid expansion & overflow.
7. Melting of metals and thermoplastics. Loss of ductility and effects on metals.
8. Weakening of soldered seams.
9. Distortion of warping of parts.
10. Peeling of finishes, blistering of paint.
11. Decreased viscosity of lubricants.
12. Increased evaporation and leakage of liquids (fuels, lubricants, toxic liquids).
13. Increased reactivity, gas diffusion etc.
14. Breakdown of chemical compounds.
15. Increased electrical resistance and opening or closing of electrical contacts due to expansion.

The Causes of temperature rise are also many and include generation or absorption of heat from - fire or explosion, electrical heating, solar heating, friction, spark, gas compression, hot weather, hot working of metal, nuclear reaction, exothermic chemical reaction, lack of insulation from thermal sources, failure of cooling system, poor heat dissipation capacity, biological, physiological or organic decay processes.

Similarly there are hazards of low temperature also.

5.4.2 Problems in Cold Environment:

Adverse effects of cold stress are. mental dullness, poor decision making and loss of consciousness (at 32 to 30°C body temp.) As protections, insulating dry clothing (e.g. woollen sweaters, mufflers, coat etc) must be provided to workers, if they have to work below the atmospheric temp. 4°C (40°F).

Local tissue freezing may occur at temp <- 1°C (32.2°F) irrespective of wind speed. At air temp = 2°C (35.6°F), wet clothing should be immediately changed. As wind speed increases or/and air temp decreases, number of breaks should be increased and work period should be decreased.

Control measures increase with decrease in temperature as under -

To work below	Protection includes
16°C (60.8°F)	Warm air jets, radiant heaters; contact • with warm plates.
-1°C (30.2°F)	Tool handles and control bars should have thermal insulation.
-7°C (19.4°F)	Warning for not contacting by bare skin. Warming shelters like tents, cabins, rest rooms should be provided nearby.
-17.5°C (0°F)	Mittens for hand protection.

Chilled wind should be diverted or obstructed by partitions or shielding. Contact of evaporative (low boiling) liquid should be avoided otherwise chilling effect will increase by evaporative cooling.

Such protections are hardly required in our country due to moderate temperature.

5.5 Control of Heat Stress:

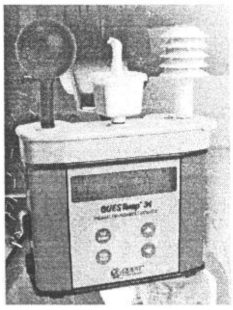


Fig. 10.7 Portable Heat Stress Monitor

Heat stress should be measured to find appropriate control measure. Heat stress monitors with or without air probe are available and they are useful for area heat stress monitoring. Personal heat stress monitor with sensor is available for personal heat stress monitoring.

Fig. 10.8 Personal Heat Stress Monitor

How to control atmospheric conditions so that varying effects on workers can be reduced to a minimum is a good task for safety engineers. The remedies varying from plant to plant should be determined from the specific study of the plant (including workers) itself. Ventilating system which moves and filters the air and which controls the temperature and humidity is a good control. Various engineering, administrative, statutory and personal protective controls can be applied to minimise heat stresses. Methods of engineering control and personnel management are given below:

5.5.1 Methods of Engineering Controls :

Refer heat balance equation in part 5.1. Then to control the effects of parameters M, C, R & E following control measures are necessary :

To reduce heat of metabolism i.e. gain by M - Reduce level of physical activity by sharing work load with others or by using mechanical means. Schedule cooler periods for work. Increase rest periods.

To reduce high air temperature i.e. gain by C - Insulate hot equipment. Provide canopies with fans over hot equipment to drive away hot air. Improve general and localised ventilation over personnel. Provide exhaust ventilation, local cooling, evaporative cooling, refrigeration, isolation, substitution, relocation and redesign as per need. Use ventilated suits against excessive heat.

To reduce radiation temperature, i.e. gain by R - Insulate hot 'equipment. Use reflective or absorptive shielding between the heat source and man. Paint the surface of hot equipment or shield or clothe it by using white colour for short wave of solar radiation and aluminium colour for infra red radiation. Wear protective clothing of reflective surface of polished metal or paint or ventilated suits. Interpose line of sight barrier. Cover exposed parts of the body. Use fans to move air and exhaust ventilation.

To reduce high humidity (restriction on loss by E) - Prevent steam leaks. Improve general ventilation. Apply dehumidification in confined spaces. Use ventilated suits for high humidity. Decrease humidity and increase air speed.

5.5.2 Methods of Personnel Management (Administrative efforts):

1. Provide ample supplies of cool water or flavoured drinks.
2. Provide extra salt where required.
3. Ensure lightweight, loose fitting clothing. In conditions with no radiant heat load, use as little clothing as possible. With high radiant heat loads, clothing should cover skin; where possible, clothing should be of cotton and white.

4. Ensure quickest development of acclimatisation. Lack of salt, lack of water or poor physical condition retards acclimatisation.
5. Where possible do not employ men in hot conditions if they are : obese, suffering from any cardiovascular disease, suffering from or recovering from febrile illness, over 45 years of. age, physically unfit and suffering from any skin disease or if they fail to sweat properly.
6. Where possible, arrange for men who are to work in hot surroundings to spend their first two weeks working in cool surroundings in the morning and in the heat in the afternoon. (This - will help acclimatisation)
7. Analyse Working situations for estimation of heat load through various channels. Apply physical methods to control hazard; if necessary amplify by control of work and rest routine.
8. Rest periods should be taken in cool surroundings. Men may effectively 'cool off even when they continue to work in cool conditions.
9. In extreme conditions man may : wear ventilated suits, be pre-cooled by immersion in cool water and be cooled down by spraying them with cool water.
10. Train in first-aid for heat strain symptoms.
11. Pre-employment and periodic medical examinations for proper placement of individuals considering their age, sex and physical fitness and
12. Observation of individual physiological responses to heat and to change their job or place if necessary.

Acclimatisation is an important factor for a worker to work for a long period in hot environment. Acclimatisation means the habit by which a person adapts himself to living and working in a hot and humid atmosphere. It is manifested as a reduction in the heart rate and internal body temperature at the expense of increased sweating.

The factors affecting physiology of acclimatisation are (1) Process of thermal regulation (2) Cardiac output and heart rate (3) Sweating.

Sweating starts when the skin temperature exceeds 33 °C. There are some 25 lacs sweat glands in a body of 70 kg man. During the period of acclimatisation, the sweating rate may rise from 1.5 lit/ h to 3.5 lit/h. The maintenance of a body temperature 37 °C is achieved by constant adjustment of the process of thermogenesis and thermolysis. An acclimatised person should not lose more than I lit/h and the rectal temperature should not exceed 38 °C.

The following factors help acclimatisation to high temperatures:

1. Persons having less than 50 kg body weight, more than 45 years of age and maximum oxygen consumption less than 2.5 lit/min should not be selected. Females get difficult to acclimatise.

2. Liquids should be taken in small quantities and often from the start of exposure to high temperatures.

3. The intake of fatty foodstuffs should be reduced.

4. Small doses of vitamins B and C are supplementary.

5. Work breaks during shift should be increased. During rest cold drinks reduce stress.

6. Heat resisting barriers which include insulation over the heat source, polished reflectant shields, absorbent shields (being cooled by air or water) and personal protective equipment (e.g. water jacketed clothing).

5.5.3 Statutory Requirements :

See Part 2 and 6.4 for statutory requirements to control heat stress.

6 GENERAL CONSIDERATIONS FORVENTILATION

6.1 Definitions :

Following definitions are useful to understand ventilation systems:

Micron: A unit of length, the thousandth part of I mm or the millionth of a meter (approximately l/ 25,000 of an inch).

Aerosol: An assemblage of small particles, solid or liquid, suspended in air. The diameter of the particles may vary from 100 microns down to 0.01 micron or less, e.g., dust, fog, smoke.

Mists: Small droplets of materials those are ordinarily liquid at normal temperature and pressure.

Vapor: The gaseous form of substances which are normally in the solid or liquid state and which can be changed to these states either by increasing the pressure or decreasing the temperature.

Dust: Small solid particles created by the breaking up of larger particles by processes like crushing, grinding, drilling, explosions, etc. Dust particles already in existence in a mixture of materials may escape into the air through such operations, as shoveling, conveying, screening, sweeping, etc.

Fumes: Small, solid particles formed by the condensation of vapors of solid materials.

Gases: Formless fluids which tend to occupy an entire space uniformly at ordinary temperatures and pressures.

Air Cleaner: A device designed for the purpose of removing atmospheric airborne impurities such as dusts, gases, vapors, fumes, and smoke. (Air cleaners include air washers, air filters, electrostatic precipitators and charcoal filters.)

Comfort Zone (Average): The range of effective temperatures over which the majority (50% or more) of adults feel comfortable.

Dust Collector: An air cleaning device to remove heavy particulate loadings from exhaust systems before discharge to outdoors. Usual range: loadings 0.003 grains per cubic foot and higher.

Entry Loss: Loss in pressure caused by air flowing .into a duct or hood (inches HO).

Hood: A shaped inlet designed to capture contaminated air and conduct it into the exhaust duct system.

Capture Velocity: Air velocity at any point in front of the exhaust hood necessary to overcome opposing air currents and to capture the contaminated air at that point by causing it to flow into the exhaust hood.

Manometer: An instrument for measuring pressure; essentially a U-tube -partially filled with a liquid, usually water, mercury or a light oil, so constructed that the amount of displacement of the liquid indicates the pressure being exerted on the instrument.

Minimum Design Duct Velocity: Minimum air velocity required to move the particulates in the air stream, fpm.

Plenum: Pressure equalizing chamber.

Natural Ventilation: Supply of outside air into a building through windows or other openings due to wind outside and convection effects arising from temperature or pressure differences (or both) between inside and outside of the building.

General Ventilation: Supply of outside air either by positive ventilation or by infiltration into the building.

Positive Ventilation: Supply of outside air by mechanical device, such as a fan.

Dilution Ventilation: Supply of outside air to reduce the air-borne contaminants in the building. It may be due to natural or mechanical ventilation.

Exhaust of Air: Removal of air from a building and its disposal outside by mechanical device such as a fan.

Mechanical Ventilation: Supply of outside air either by positive ventilation or by exhaust of air (causing reduction of pressure inside), or by their combination.

Local Exhaust Ventilation: Ventilation effected by exhaust of air through an exhaust appliance, such as hood with or without fan located as closely as possible to the origin of contaminants so as to capture effectively the contaminants and convey them through ducts to a safe point of discharge (e.g. dust collector, scrubber, flare etc.).

Dry Bulb Temperature: The temperature of the air read on a thermometer, placed in such a way as to avoid errors due to radiation.

Wet Bulb Temperature: The steady temperature finally given by a thermometer having its bulb covered with gauze or muslin moistened with distilled water and placed in an air stream of not less than 4.5 m/s.

Humidity Absolute: The weight of water vapour per unit volume, lb/ft" or g/cm"

Humidity Relative: The ratio of the actual partial pressure of the water vapour in a space to the saturation pressure of pure water at the same temperature.

Humidification: The process whereby the absolute humidity of the air in a building is maintained at a higher level than that of outside air/or at a level higher than that which would prevail/naturally.

Due Point: When the temperature of a saturated space is reduced, more moisture will condense than evaporate until equilibrium is again reached. The temperature at which saturation occurs and condensation begins is the due point or saturation temperature.

Spray-head System: A system of atomising water so as to introduce the moisture directly into a building.

Make Up Air: Outside air supplied into a building to replace the air removed.

Air Change per Hour: Ratio of the outside air volume allowed into a room in one hour to the room volume. .

6.2 Air Requirement:

Before studying the types of ventilation, it will be useful to know about the required air composition and air movement. It is given table 10.2 :

Table 10.2: Air Composition (Percentage Volume)

Component	Outdoor air Dry	Indoor air 20 °C RH 50	Expired air 36 °C RH 100
Oxygen	20.97	20.69	16
Carbon dioxide	0.03	0.06	4
Water vapour	0.00	1.25	5
Inert gases (Nitrogen Argon etc.)	79.00	78.00	75
	100.00	100.00	100

Thus ventilation is necessary for not allowing the air components to reach their expiry limits. Minimum six air changes per hour are necessary in a workroom.

A person working hard, breaths about 40 litres of air per minute, consumes about 2 litres of oxygen and exhales about 1.7 litres of carbon dioxide. A sleeping person consumes only about 1/10 of this amount. Air movement below 0.075 m/s gives feeling of stagnation and above 0.4 m/s a perceptible draft. Its comfortable range is O.I to 0.3 m/s. :

Fresh air supplies oxygen to the human body. Normal air requirement is 20 m" to 30 I113 per person per hour. Fresh air supply and movement reduces heal stress by dissipating heat from body by evaporation of the sweat when relative humidity is high and the au temperature is below or near body temperature.

If sensible heat H in Kcal/h (i.e. heat due to sun, process emission and exhaust of occupants) and allowable temperature t in °C are known, the volume of outside air Q in "/h, required to remove the sensible heat is given by -

$$Q = \frac{3.462 \times H}{t}$$

6.3 Control Criteria :

In addition to the composition, amount, temperature and movement of air, the airborne contaminants including dust, gas etc., also need to be controlled.

Mechanical ventilation becomes necessary to prevent their concentration. Toxicity, rate of generation, concentration, exposure time and workers' susceptibility should be considered while controlling air borne contaminants by ventilation. Elimination of dangerous materials creating contaminants, reducing its concentration by dilution ventilation and preventing its accumulation by removing the contaminants at its point of origin by local exhaust ventilation and isolating the process in a sealed system (preferably under vacuum) are most important engineering factors to be considered while designing appropriate ventilation system. Use of respiratory protection, good housekeeping and training are additional complementary factors.

Generally two streams (jets) are important, those containing hot or contaminated air from machines or processes and those containing fresh air from openings or ventilation grills. Their mixing causes dispersion and dilution. Their rates should not be excessive. Draughts of fresh or cool air also cause discomfort. Exhaust hoods must be placed very close to a source of heat or contaminant to prevent their escape in surrounding.

Air cleaning devices are used to remove contaminants from the air or .gas stream. They are available in a wide range of varieties. Their selection criteria are:

1. Particle size and concentration of contaminant.
2. Characteristics of the air or gas stream.
3. Characteristics of the contaminant.
4. Degree of collection required, and
5. Method of disposal.

The equipment works on following principles:

1. Gravity forces.
2. Centrifugal forces.
3. Electrostatic forces.
4. Scrubbing, and
5. Impactiation.

Equipment available are of the types : Settling chambers, 'Gravity traps, Rotoclone, Cyclone separator, Multicyclones, Wet cyclone. Fabric filters. Electrostatic precipitators and Scrubbers.

6.4 Some Design Factors :

The main objects of ventilation design are to supply fresh air for respiration, to dilute air to prevent ventilation by body odours, to remove any contaminants in air, and to provide such thermal environment to maintain heat balance of the body in order to prevent discomfort and injury to health of the occupants. For this purpose it may be necessary to either decrease (cooling) or increase (heating) the workroom temperature, to control the humidity and to regulate the rate of air movement. Thus industrial ventilation is an integral part of air conditioning when it is used in combination with heating, cooling and humidifying appliances to maintain satisfactory condition for the product or the occupants.

Ventilation is useful for heat and contaminant controls and is accomplished by air stirring or supplying fresh air or removing unwanted air or by their combination. Where flammable gases are used or emitted, the ventilation is needed to keep the atmosphere safe from ignition. Electric fittings should be flameproof.

The supply openings i.e. inlets into the room should be located near the occupants if possible and opposite to that should be the air-return openings. The supply outlets should also be directed towards or over the occupants so that air moves from the fresh air supply in the direction of the occupants and then out of the returns and exhaust hoods.

The amount of ventilation required depends on:

1. Size (including height) and type of room and its usage.

2. Duration and type of occupants and their activities.
3. Heat gains from sun, hot processes, machinery, electrical equipment and occupants.
4. Comfort conditions required inside the room.
5. The operation of the ventilation system.

Generally 20 to 30 m" air per person per hour, at least 6 air changes per hour and 14 to 16 m3 space (limited to the workroom height 4.25 m) per worker are recommended for ventilation where there are no contaminants to be removed from air. Excess heat from a hot environment has to be offset to maintain normal body temperature 37 °C. Normal energy expenditure in moderate work by a man is 235 to 330 Kcal/h for which maximum wet bulb temperature shall not exceed 29 °C and air movement (velocity) of more than 30 m/min shall be necessary.

Rule ISA of the Gujarat Factories Rules (GFR) requires that -

1. Wet bulb temperature in a workroom should not exceed 30 °C (thermometer htl.5 mt).
2. Air movement should not be less than 30 m/main
3. Dry and wet bulb temperature should be as under –

Dry Bulb Temp (°C)	Wet Bulb Temp (°C)
30 to 34	29
35 to 39	28.5
40 to 44	28
45 to 49	27.5

4. Ventilating openings (D, W & V) in a workroom should be more than 15% of the floor area and so located as to afford a continued supply of fresh air at workers' level.

5. Quantity of fresh air supply by mechanical means should be six times the workroom volume (m') per hour. It should be evenly distributed in the' workroom.

6. In summer when temperature exceeds 35 °C and humidity more than 50% permissible in the workroom, desert coolers or central air washing plant can be suggested by the Inspector.

7. Above limits are not applicable where artificial humidification (Sec. 15 of the Factories Act), refrigeration or high process temperature are applicable.

Generally more than 60 m/min air velocity shall be avoided unless the temperature and humidity are high. In case of heavy manual work, if the air is capable of absorbing heat from the body, an air-blast up to 300 m/min may be directed at the workers for velocity and evaporative cooling. Capture velocities (0.25 to 10 m/s) for local exhaust ventilation for contaminants control are given in Table-3 of IS:3103. The rate of air flow in the duct or grille shall be within 10% of the amount required and variation of air flow through filters and grilles shall not exceed ± 20% of the mean value.

The dry and wet bulb temperatures shall be maintained as per the schedule given by the Factories Rules or IS:3103. In case of industrial building wider than 30 m, the ventilation may be augmented by roof ventilation. Ventilation rates of 30 to 60 m3/h/ 2 of floor area have been found satisfactory. Where the desired temperatures and humidity cannot be obtained by mere ventilation, air conditioning may be resorted to as per IS:659 and 660.

7 TYPES OF VENTILATION

7.1 Classification of Ventilation Systems :

For better grasping, major ventilation systems are classified as below :

Ventilation Systems

- Natural Ventilation
  1. Dilution or Cross ventilation (Wind action)
  2. Roofed ventilation (Stack action)
- Mechanical Ventilation
  - (A) For Building
    1. Exhaust or Negative Ventilation (Induced draft)
    2. Plenum or Positive Ventilation (Forced Draft)
    3. Combined or Compound Ventilation
    4. Roof Ventilation
    5. Comfort Ventilation (Air Conditioning)
       - (a) Refrigeration
       - (b) Heating
       - (c) Humidity Control or Evaporative Cooling
  - (B) For Contaminants Control
    1. Dilution or forced Ventilation
    2. Local Exhaust or Extract Ventilation
    3. Emergency Ventilation

Ventilation systems are of two types (1) Supply air system and (2) Exhaust system. Supply air system has two purposes (A) heating, ventilating and air conditioning (HVAC) for comfortable environment and (B) to replace exhausted air from the plant. Exhaust system is of two types: General and Local exhaust type. General exhaust system is for heat control and/or removal of contaminant by dilution ventilation and Local exhaust system is for capturing contaminant at source.

The details of these varieties of ventilation and calculation methods occupy much space. Their design is a specialised job for ventilating engineers. Here they "are explained in brief as follows.

7.2 Natural Ventilation :

Natural ventilation is induced because of two reasons (1) outside wind pressure i.e, wind action and (2) temperature difference of the air inside and outside the room i.e. chimney effect. There is a positive pressure on windward side and negative pressure on leeward side. By providing adequate openings in these pressure areas, natural ventilation can be achieved.

The rate of ventilation by natural means through windows or other openings depends on direction and velocity .of wind outside, solar radiation, size and disposition of opening (wind action), convection currents arising from temperature or vapour pressure difference (or both) between inside and outside the room and the difference of height between the outlet and inlet openings (stack effect). They are of two types as under

(1) Dilution or Cross Ventilation: Inlet openings should be located on the windward side at a low level and outlet openings should be located on the leeward side near to the top so that incoming air stream is passed over the occupants. Greatest flow per unit area opening is obtained by using inlet and outlet openings of nearly equal areas. Under the Factories Rules ventilation opening area in a work room shall be at least 15% of the floor area. At least 10% of the floor area shall be located at not more than one meter sill level height from the floor level. Wind velocity in hot weaver should be 40 to 60 mt/min. Ventilation due to wind outside is given by the formula Q = kAV given in Part-9.

Inlet openings should not be obstructed by surrounding buildings, walls, partitions, trees and other obstructions in air path. Great advantage is available by providing windows in west and east direction. However if wind direction is not effectively available, openings in all four sides can help the natural ventilation.

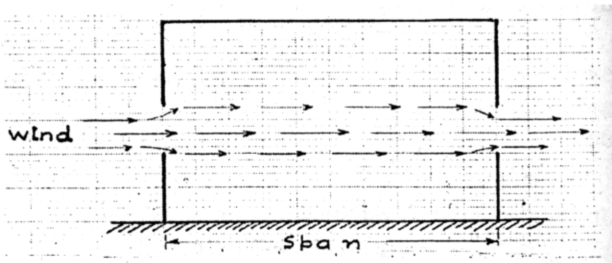

Fig. 10.9 With flat roof, cross ventilation is effective when span is less than 20 meters.

When the room temperature is higher than that of outside because of hot processes, season etc., cool outside air tends to enter through openings at low level and warm air tends to leave through openings at high level. Therefore it would be advantageous to provide ventilators near to the ceilings.

(2) Roofed Ventilation : Cross ventilation suitable for narrow building is not much suitable for large buildings and where roofed ventilation is suitable. Here ventilators are provided in roofs viz. cowl, vent pipe, covered roof and ridge vent to give stack effect.

For a 60 cm (24 in) diameter cowl type ventilator the formula's -

$Q= A (8 \sqrt{H(t_i-t_0)}+5.82V)$

Where Q = capacity of the ventilator in m3/min, A = cross sectional area of the ventilator in 2 H = height of the ventilator above the inlets in m, t. and t are the inside and outside temperatures in °C and V = wind velocity in kmph.

See fig. 10.10 for different types of roof and fig. 10.11 for modified roof ventilation.

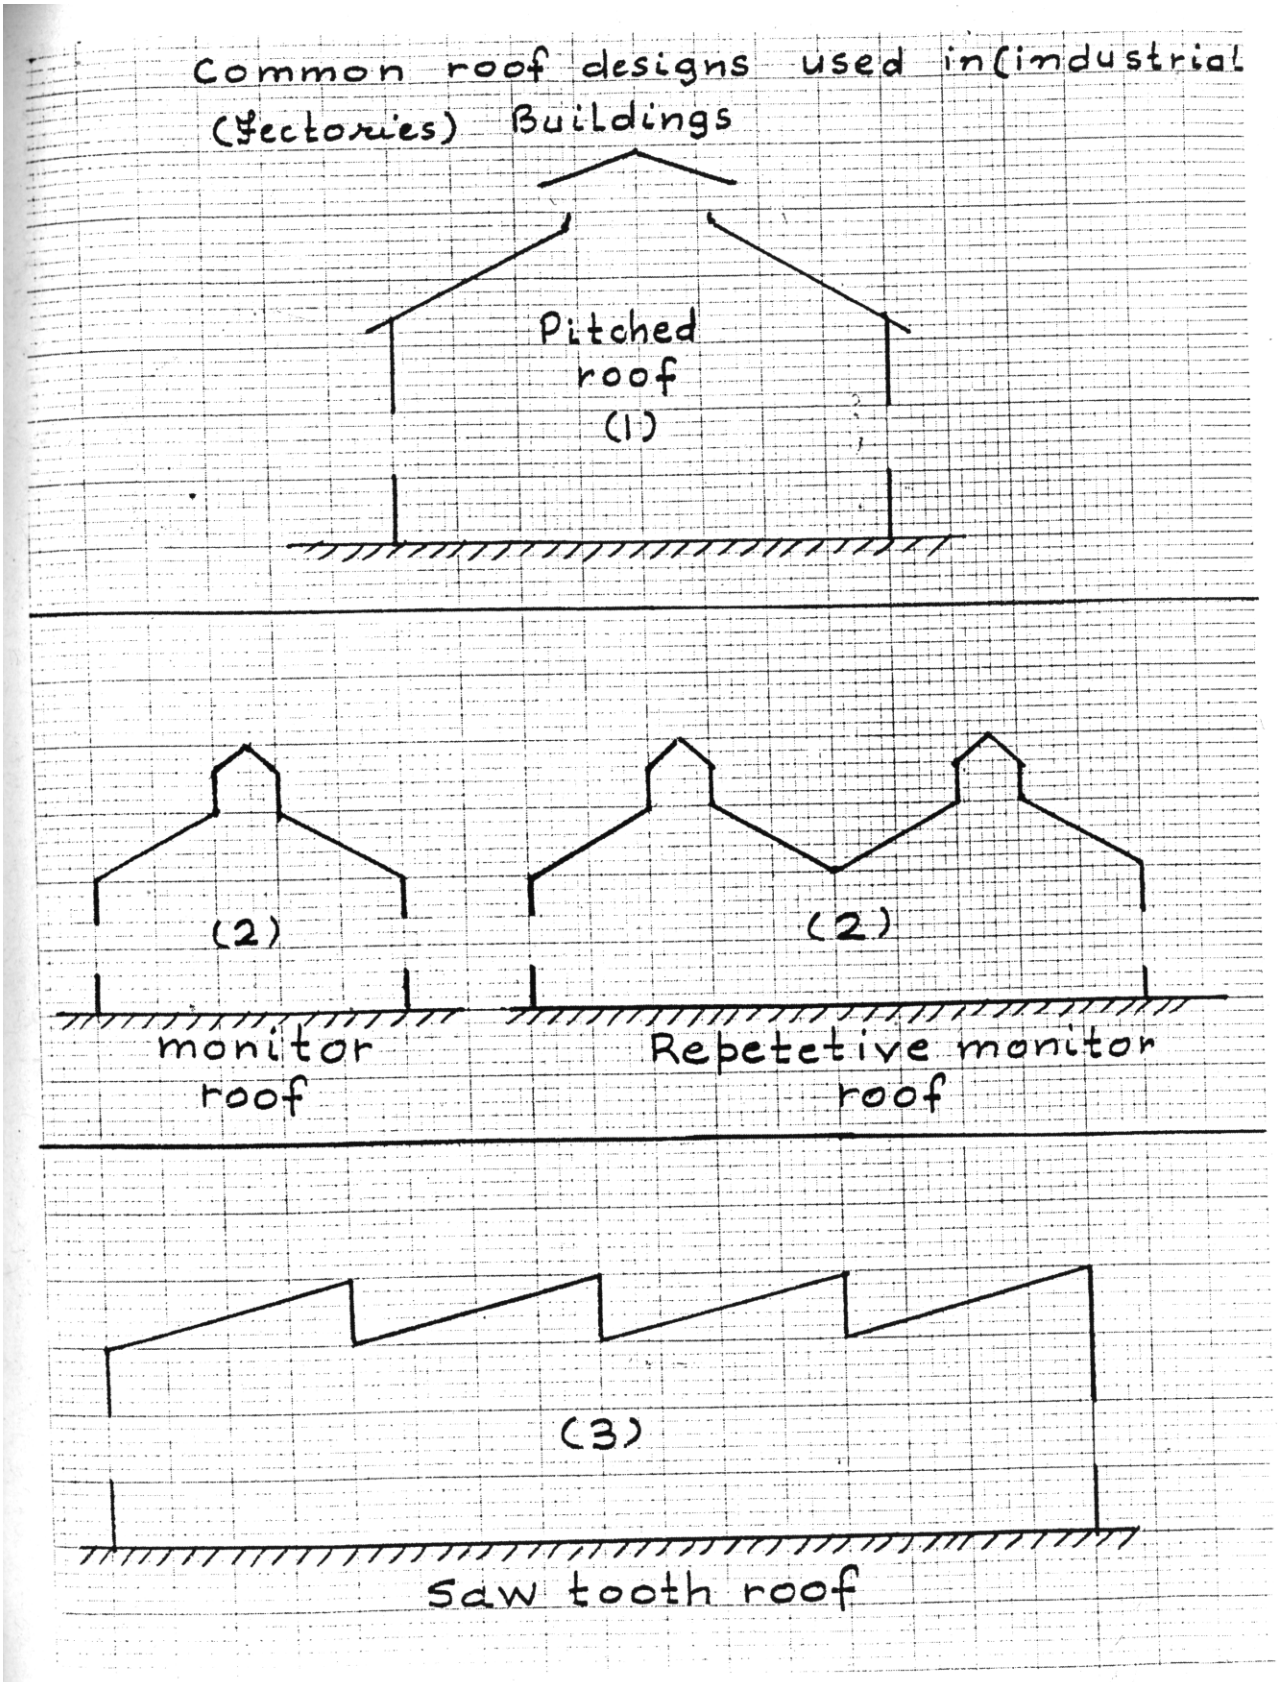

Fig. 10.10 : Types of roof for natural ventilation,.

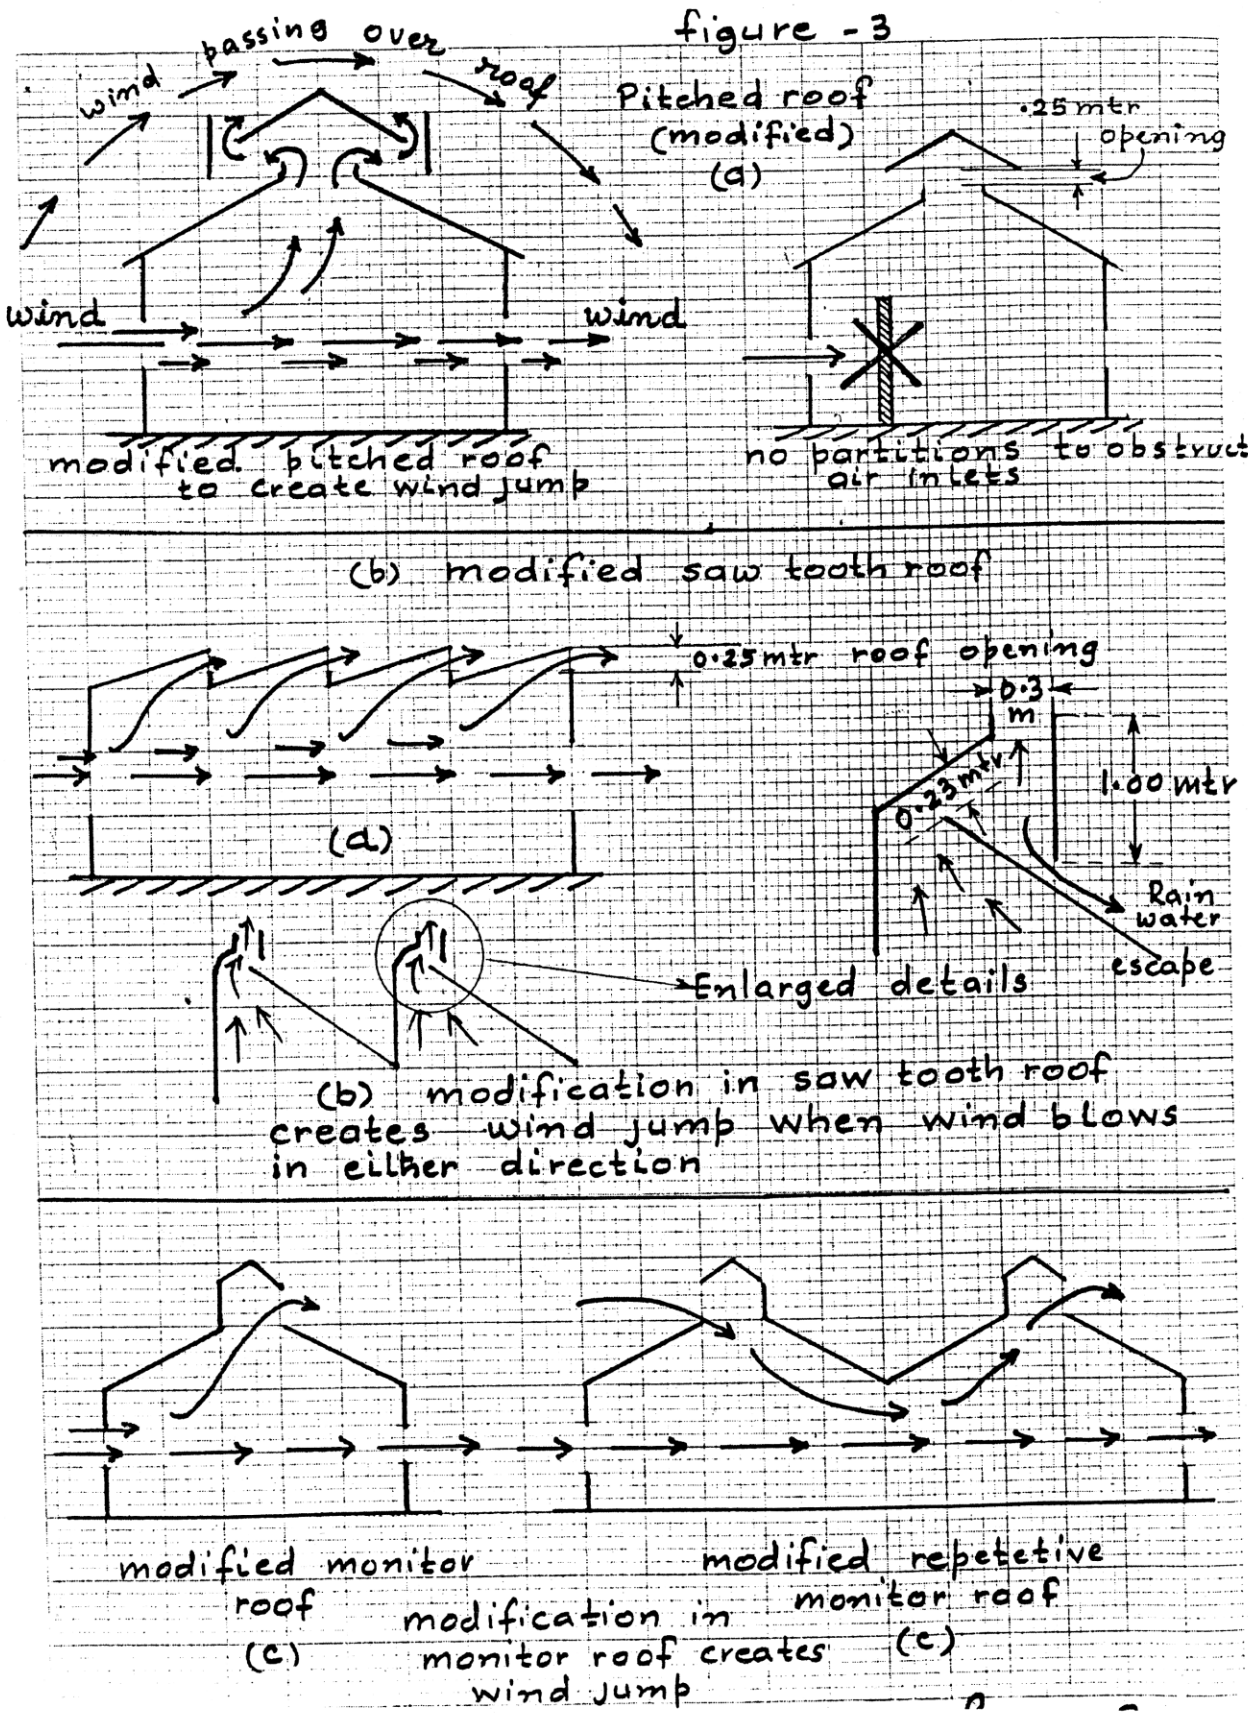

Fig. 10.11 : Modified pitched roof and monitor roof.

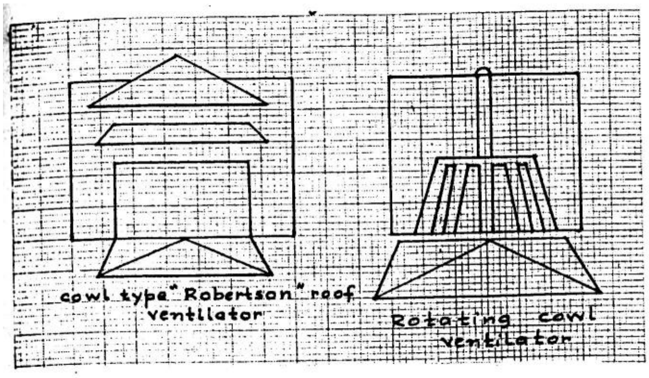
In roofed ventilation, natural ventilation is used by chinmey (stack) effect due to temperature difference. This effect is counteracted by wind blows straight against roof openings. By suitable design of itched roof, saw-tooth roof or monitor roof this interference can be reduced.

Cowl type Roof Ventilation : Fixed or rotating owl (hood on roof vent) is provided to accelerate natural roofed ventilation. The performance of roof cowls depends on temperature difference between inside and outside air, velocity of incoming wind, cross sectional area of the ventilator and its height above air inlet. For a 60 cm (2 ft) diameter cowl, air flow capacity is given by the formula stated above.



Rotating cowl requires a lubricant reservoir for its long service to run without jamming.

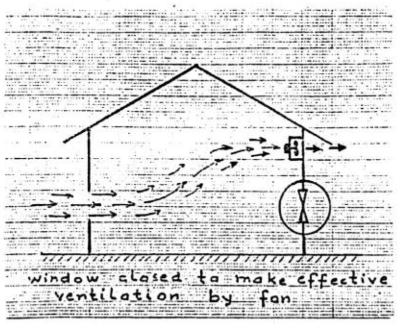
7.3 Mechanical Ventilation :

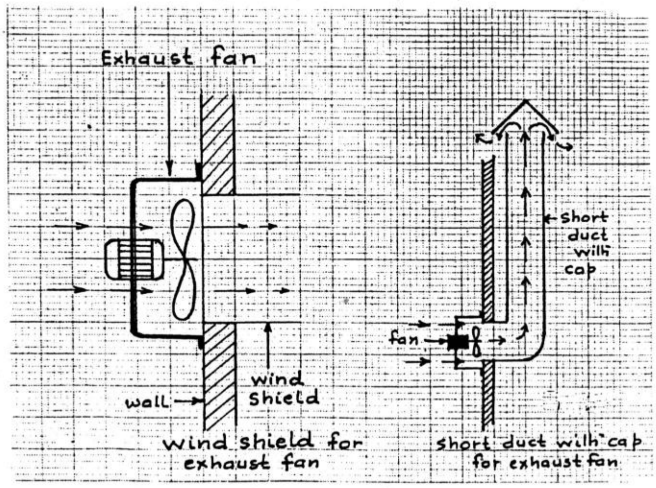
Mechanical ventilation is employed for building i.e. workroom and also for process for removal of contaminants. Both the types are explained below.

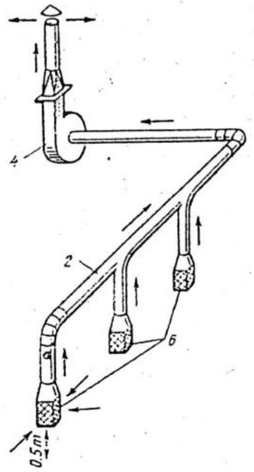
7.3.1 Building Ventilation:

These are of many types as classified earlier. When natural ventilation is not sufficient to keep thermal environment within the limits specified by dry and wet-bulb schedule under the Factories Rules, or where the span of work room exceeds 18 meters or where any work place is more than 9 meters away from a ventilation opening, mechanical ventilation (exhaust, positive or their combination) shall be provided and in case of positive ventilation, air shall be cleaned and cooled before sending into the work room.

(1) **Exhaust or Negative Ventilation:** Exhauster induced draft fans are provided in walls on one side of the building or in the attic and roofs to draw large volumes of air through building. These fans are generally propeller type. The windows and other openings near the fans should be kept closed to avoid 'short circulating of air'. Adequate inlet openings shall be provided on opposite side of the building to limit inlet velocities. When fans are centrally located on an attic or arranged to draw from exhaust appliances with ducting, they should be centrifugal or axial types to overcome duct resistance. The total inlet area should be at least 3 times the total disc area of the fan.







The exhaust fans should have wind shields on outside of the wall so that wind pressure may not decrease their efficiency. The fans discharge should be diverted into large ducts carried vertically upwards with rain water cap at the top. Fans should have proper guarding or fencing.

(2) Plenum or Positive Ventilation : It is provided by centrally located supply fans (generally centrifugal type) having a wide range of capacity and quiet operation. Air-tight ducts increase the advantage. Unit ventilators should be provided for individual rooms and may be placed against outside wall near the central line of the room. Evaporative cooling coils can be incorporated for cooling purpose.

Plenum ventilation is useful for large workrooms where exhaust ventilation is normally not effective. Its air movement and regulation are more than that by exhaust ventilation. Better dilution of contamination is also possible. The air velocities should not be excessive to disturb manufacturing processes. Good distribution can be achieved by using diffusers or swivel type ejector nozzles at high velocity at the inlets. For positive ventilation, the volume of air is given by Q = AV, where Q = air volume in m''/ in, A = free area of intake openings of ducts in m' and V= average velocity of air in m/min.

The positive air pressure inside the room disallows outside hot or cold air leakage inside.' Better dilution is achieved. Ducts should be smooth, straight, with minimum bends and without sudden enlargements or contractions. The air velocity should not be too excessive to interfere with the manufacturing process or be unpleasant. Discharge nozzles should discharge air horizontally at a height little above the heads of the workers. Air velocity in a duct should be @10 m/s for gases and @20 m/s for particulates.

(3) Combined (Compound) Ventilation : It is the combination of positive and negative (exhaust) ventilation with the advantage of better air distribution over the entire area of a large building. By supplying proper volumes of air at suitable velocities at the required areas through duct and by extracting the air in the return duct and re-circulating this air after proper cleaning and mixing it with cool fresh air, good results can be obtained. It is preferable to provide slight excess of exhaust if there are adjoining occupied spaces and a slight excess of supply if there are no such spaces. Unit exhausters can be used to match with unit ventilators exteriors and located along the outside wall.

(4) Mechanical Roof Ventilation : It is used for augmenting natural ventilation in buildings with large width (>30 m) or where the heat load is very heavy. Exhaust fans exercise very little influence beyond a velocity contour at about 15 m/min which is a short distance from the fan. The volume of air required in removal of sensible heat gained (in Kcal/hr) can be calculated from the formula -

$$Q = \frac{\text{Kcal/hr} \times 3.462}{\text{Temperature rise in } ^\circ\text{C}}$$

where Q is the volume of air in m^3/hr, and allowable temperature rise = Inlet opening temp. Outside temp., is given by following approximate figures.

Roof elevation in mt	Rise in °C
6	3 to 4.5
9	4.5 to 6.5
12	6.5 to 11

These values are at roof exit and not the floor temperatures. The maximum allowable temperature rise for an air stream as it leaves the grills and reaches the working level is 1.7 to 2.8 °C (5 °F).

(5) Comfort Ventilation: It is the method by which the interior of a room is heated or cooled or the humidity altered for process control or comfort conditions.

As refrigeration is very expensive, evaporative cooling may be adopted with advantage where summers are dry with low wet bulb temperatures. The quantity of air required for ventilation could be reduced if the outside air is cooled before the air is discharged into the building. Although the relative humidity of supply air will be increased but due to the large sensible heat loads, the resultant relative humidity in the workroom will be lowered after mixing with the inside air to produce body cooling.

Water spray chamber and a fan to supply outside air into the workroom through a distribution duct is preferable to spray which only humidifies the air where the cooling capacity of the air is not much improved and no hot air is removed from the building.

Evaporative cooling is generally used in cotton textile mills where humidification is necessary to meet the process conditions. It can also be used in chemical plants (where water is not reactive), non-ferrous casting shops, tobacco factories etc. It is useful in rubber factory to prevent static electricity due to solvent and in printing or lithographic works to maintain paper size. It is suitable where dry bulb temperature is 35 °C (95 °C) or more, wet bulb temperature 25 °C (67 °F) or less and relative humidity 5% or more during 15th March to 15th July as required under Rule 18A(3) of the Gujarat Factories Rules.

The spray chamber (air washers) and single or multi bank up or down spray system can be designed after careful considerations. Make-up water in circulation (about 1.5 to 2%) can be calculated from evaporation losses, bleed off losses and driftage. For safety in air-conditioning and mechanical refrigeration, IS:659 and 660 shall be referred respectively.

See Part 7.5 for air-conditioning.

7.3.2 Process Ventilation (Contaminants Control):

Mechanical ventilation is also employed for contaminants control as follows :

(1) Dilution or Forced Ventilation : It is helpful in reducing contaminant concentration in work area to control health and fire hazards. This is useful to control less toxic vapours such as from organic solvents. It is not useful to control fumes, dusts and contaminants of high toxicity (TLV less than 100 ppm) and high quantity or concentration. It is also not useful where pollutants are released intermittently. The amount of air required for dilution can be calculated from the following formula:

Air required for dilution in m^3/kg of evaporation or generation of gas

$$= \frac{24 \times 10^6 \times F}{\text{Molecular weight of toxic gas} \times \text{TLV in ppm of liquid or gas}}$$

Where F is a factor of safety for health hazard varying from 3 to 10 and depending on the - toxicity, evolution rate of contaminant and effectiveness of the ventilation.

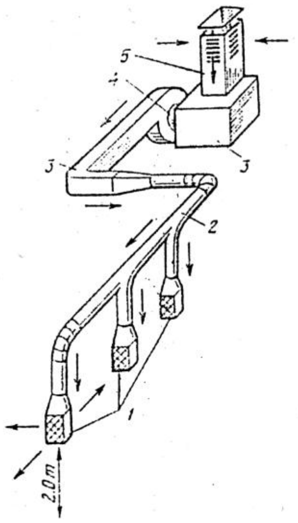
The formula for control of fire hazard is as follows:

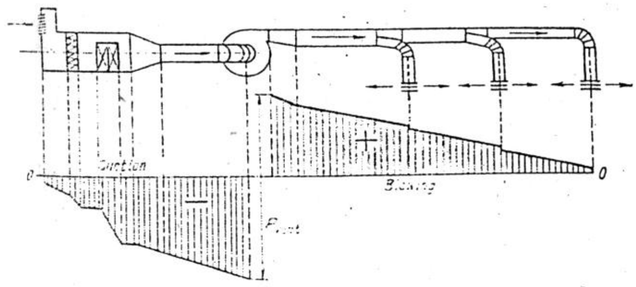
Air required for dilution in m^3/kg of flammable gas.

$$= \frac{24 \times 100 \times F}{\text{Molecular weight of the gas} \times \text{LEL} \times C}$$

Where F is a factor of safety for fire hazard varying from 4 to 12 depending upon the percentage of LEL (Lower Explosive Limit) and C is a constant which is 1 for temperatures up to 121 °C and 0.7 for temperatures above 121 °C.

Normally this method is adopted where it is impossible to fit an extractor to the work point. Hourly air changes in a work room are for dilution purpose. It should be 6 times the room volume per hour.





The air flow volume to be provided should take into account (1) the volume of the pollutants released (2) the concentration permitted in the workplace and (3) a factor of safety which allows for the layout of the room, the airflow patterns created by the ventilation system, the toxicity of the pollutant and the steadiness of its release.

(2) Local Exhaust or Extract Ventilation : It is applied at the release points of contaminants (dust, gas, fumes, particles etc.) to reduce their concentration in the workroom below TLVs. Su(;h points shall be enclosed except where access is necessary for the process, but in that case, the exhaust appliance shall confine the contaminants as much as possible.

The volume of air required is calculated from the area of openings and the capture velocity sufficient to prevent outward escapement. The sizes of the ducts shall be calculated from the volume of air required and duct velocities necessary to convey the contaminants with minimum static resistance.

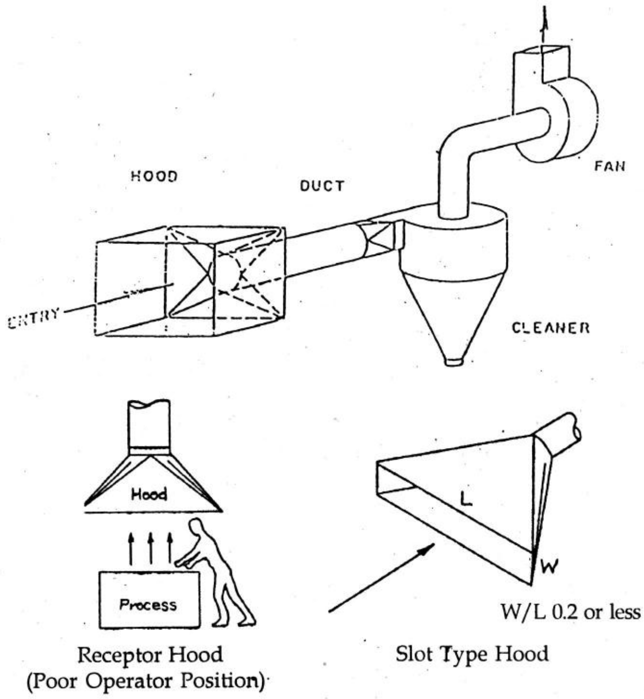


Fig. 10.12 Elements of a local exhaust System

Capture velocities may vary from 0.25 to 10 m/ s proportionately increasing with the contaminants velocity as given in Table-10.3. The test report for dust/ fume extraction system shall be in form No. 26A under the Gujarat Factories Rules.

Where the emissions of heat or contaminants are high, dilution ventilation is not fully effective and the well designed exhaust ventilation becomes necessary."

Exhausted air may be re-circulated after cleaning and filtering to increase the rate of mechanical ventilation.

Hood, duct, air cleaning device, filter or collector (to separate contaminant from the air before discharging it into atmosphere) and fan and motor (for air flow) shall be designed or selected properly.

Hoods are of many types - booth, canopy, side draft, cabinet, single or double lip and push and pull type

Duct may be square or rectangular, with material to resist abrasive or corrosive action. Sharp corners shall be avoided. Cleaning and trapping gates shall be provided. Generally the conveying velocity may be from 10 to 25 m/s depending upon the type of contaminant and balancing of equal flow rate of air.

Types of air-cleaners, dust separators or collectors are settling chambers, cyclones, dry dynamic precipitators, scrubbers, wet collectors, electrostatic precipitators, fabric filters and air cleaners for gases and vapours. The fan selection depends upon air volume and static pressure required. A guide for selection of collectors is given as Table-18 in Chapter-32.

Points to be considered while **designing a hood** are :

1. Enclose the operation as much as possible. Hood should be as near as possible to the source of generation. Doubling the distance require approximately four times the air volume.
2. Hood should be so located as to keep the flow of contaminants away from the worker.
3. Hood should be so placed as to take advantage of initial velocity and direction of the throw of the contaminant. For example, lighter vapour, hot substances, gas tending to rise, should be collected by hood overhead, while heavier particles or gas/ vapour with vapour density > I and tending to settle, should be collected by placing hood down or at the side.
4. Hood should not interfere the movement of the operator and the job.
5. Portable power drills, grinders, saws etc. should have machine attached extractor and dust collection chamber to be carried on back or on wheels to suck the particles flying at the point of operation. Fixed machine like carding machine also needs extract ventilation.

Minimum capture velocities are given in Table 10.3, for the capture of dusts, fumes, gases, smokes, mists etc.

Table 10.3 : Recommended Capture Velocities:

Releasing Velocity	Minimum Capture Velocity in		Examples
	fpm	m/s	
Low, into quiet air	50 to 100	0.25 – 0.5	Evaporation or fumes from open vessels, degreasing, pickling, plating.
Slight, into moderately quiet air	100 to 200	0.5 – 1.0	Spraybooth, low speed conveyor, cabinet, welding, dry dumping.
High, into rapid air movement	200 to 500	1.0 – 2.5	Spray painting in small booth with high pressure, conveyor loading, barrel filling, crushers.
Higher, into very rapid air movement.	500 to 2000	2.5 – 10	Grinding, blasting, rock, surfacing, tumbling.

Note : Similar to Table 3, IS:3103

See part 10 for worked examples.

(3) Emergency Ventilation : It is a type of mechanical local exhaust ventilation where specialised air ducts for delivering air may not be necessary. It is useful in gas-generating plants and compressor-rooms where risk of sudden outburst of explosive or flammable gases or vapours exists. At least 8 air changes per hour is necessary. Axial fans are selected for spark-free operation. Automatic switches are required to operate the system at the time of emergency.

(4) Other Methods : Despite of above three types of ventilation system for contaminants control, other methods of prevention are: Substitution, segregation, enclosures, natural and general mechanical ventilation, wet methods, use of personal protective equipment and warning and publicity.

In **substitution** safe substitute should be found for a toxic material.

In **segregation** the hazardous process and persons are kept away by means of suitable partition or increasing their distance.

Enclosure prevents contaminant of surrounding by physical separation of toxic material or process by enclosing them.

Wet method uses water spray to prevent dust escape into atmosphere. In

Dust suppression method jet or spray is applied to cutting tool, chisel, grinder, saw etc. to wet the surface for dust suppression.

Dust prevention includes both, wet method and dust suppression method. Using paste instead of powder, dipping in water, oil or other suspension are useful for gases, dusts and clothing. Proper personal protective equipment should be utilised as the last control against contaminants.

7.4 Air Distribution :

In any type of ventilation, proper air distribution is most important. Air should be distributed evenly without dead air pockets or undue drafts of high inlet velocities. The size and distribution of windows, inlet and outlet openings, ducts, fans, air inlet grills should be properly located considering orientation, prevailing winds and building and process layout. Normally air movement below 60 m/min without objectionable draughts should be provided in the vicinity of workers for better comfort High air movement may be required for heavy manual work. A blast of air up to 300 m/ min may be directed at the workers working in high temperature and high humidity, for velocity cooling.

7.5 Air Conditioning :

By air conditioning (AC) normally people mean 'air cooling' but it is not necessarily so. In a very cold country, room air heating (to maintain comfortable temperature) is also air conditioning. Its prime purpose is to keep air in a condition comfortable to man.

Air conditioning means conditioning the air for maintaining specific conditions of temperature, humidity, air circulation and dust level inside an enclosed space or room. The conditions to be maintained are dictated by the need for which the space is intended for.

When air conditioning is designed for human beings, it is called comfort conditioning as it keeps into account the regulated flow of air, its temperature, humidity and cleanliness most favourable, bearable and comfortable to men. But when it is designed to preserve things at low temperature, it is called refrigeration.

Why comfort air conditioning is required ? Because of physiology of heat regulation in human body only. Due to metabolism the body temperature is maintained at 37°C (98.6°F). But the skin temperature varies according to the surrounding temperature and relative humidity. When the surrounding is at very low temperature than the body temperature (e.g. cold winter), the rate of heat flow from the body (through skin) is rapid and the person feels cold. When the outside temperature is higher than the body temperature (e.g. hot summer) heat flow from the skin is restricted and the person feels heat. In this situation the water from the body evaporates at the skin surface (perspiration). This brings down the skin temperature and gives cooling effect. But if the outside is hot as well as humid, rate of perspiration will decrease and the person will feel hot and uncomfortable. Air movement by a fan accelerates perspiration and relieves discomfort.

Therefore to provide comfort by air conditioning, it becomes necessary to maintain room temperature and relative humidity at certain level so that the heat dissipation from the skin remains steady. In addition to tins, the air movement (draft) should be gentle and uniform to create a feeling of comfort. For this purpose the air delivered from the air conditioner picks up the heat and moisture from the room with a uniform comfortable air flow. The air is sucked back for mixing with fresh air and reconditioning to enable it to again pick up heat and moisture from the room. To take away the heat generated by breathing, infiltration into room through door and wall openings, electric fixtures, machines and equipment, a sufficient quantity of conditioned air has to be circulated into the room. If the room size is large, more air-distribution ducts and supply outlets (called supply grills), and more return-air grills and ducts (passages) are required for uniform effect at all points inside the room.

In summer when cooling is required, air is cooled and dehumidified by the use of refrigeration system. For severe winter regions, the air conditioner unit provides heated air to the conditioned space.

Air filters are provided before the cooling coil to arrest dust carried by the return (fresh) air. The air filters also protect the cooling coil against dust accumulation.

For small room, normally 0.75 to 2.5 tonnes capacity and for larger area 5 to 15 tonnes capacity air conditioners are required. The compressor, motor, evaporator, condenser, throttling device and air circulating fans are the main parts of any air conditioning unit.

Air conditioning processes are as under :

1. Cooling only (without humidification or dehumidification).
2. Cooling and dehumidification.
3. Cooling and/or Heating,
4. Finned cooling coils with direct expansion.
5. Cooling with humidification, and
6. Desert coolers.

The desert cooler or air cooler works on the principle of evaporative cooling. A fan sucks outside air through a wetted pad which is kept continuously wetted by circulating water through it (independent circuit). The air passes trough the wetted pad, gets cooled and humidified and discharged into the room where it picks up sensible heat and maintains fairly comfortable condition. The heated air escapes from the room openings i.e. the same air is not taken back in ducting. As a fresh air it may come back through the wetted pad.

Thus the purpose of air conditioning is to provide the most comfortable ventilation and better heat control at home and also at some specified industries (e.g. electronic, computer/telephone, watch, pharmaceutical industry).

The hazards associated with industrial air conditioning plants (e.g. chilling plants, cold storage, central AC for theatre, auditorium, dairy etc.) are:

1. Leakage of refrigerant. Ammonia leak has toxic effect and compounds of chloro-fluoro-methane has ozone depletion effect (environmental hazard). Ammonia leak is detected by smell or SO, torch (gives white smoke) and leakage of other gases by Halide torch or electronic gas detector.

   Common refrigerants are R-717 or Ammonia (NH_3), R-11 (CCl_3F), R-12 ($CC1_2F_2$), R-22 ($CHCIF_2$) and R-502 ($CHCIF_2$, + $CC1F_2CF_3$)

2. Pressure of compressed gas in cylinder, condenser and pipelines. Appropriate safety valve or pressure controller, pressure gauge, isolation valve, drain, etc. are required. Periodical pressure testing (normal and hydraulic) is also necessary.

   For safety code see IS 659 & 660.

7.6 Ventilation for Special Operations:

Open Surface tanks for anodising, pickling, acid dipping, plating, etching etc., involve heat and gassing. Depending upon the rate of evolution, type of ventilation needed may be : enclosing hood, lateral exhaust, overhead canopy hood, general room ventilation etc.

Spray Booths for spraying paint, enamel, bleaching, glazing, welding etc., require deeper spray booth or baffles of non-flammable materials.

Foundries need dust control in shake out and cleaning rooms where 'wet method may be suitable. In a mechanised foundry tight enclosing hood and side hood on the shake out gate are useful. Sand conveying and reconditioning equipment should be completely enclosed and ventilation should be provided at dust producing spots.

Grinding, buffing and polishing operations need local exhaust systems. Hoods on grinding and cutting wheel for local exhaust with an adjustable tongue to peel off the dust carried around the wheel in the air stream set up by the wheel's rotation, are desirable. Not more than 25% of the wheel should be exposed. Velocity in branch ducts and main duct may be @ 4500 and 3500 fpm respectively. Swing grinder should be housed in a booth. Portable hand grinding can be done in a booth or on a table with downdraft ventilation.

Woodworking machinery need exhaust ventilation. Cyclone arrester is used to collect scrap.

Cast-iron machining needs hood design according to the machine tool. Small local hoods with face velocities 400 to 2000 fpm may be suitable.

Similarly local hoods of special design are needed for oil melting furnaces, petrol engines etc.

8 CONTROL OF HEAT EXPOSURES

Control of heat stress is explained in foregoing part 5.5. '

control criteria, see part 6.3, and for some design factors part 6.4.

In addition to the ventilation, natural or mechanical, as explained above, it becomes necessary in process situations to apply other means for control of heat exposures toward workers. They are as follows:

8.1 Control at Source (Isolation or Segregation) :

The first obvious step is to isolate the heat sources wherever possible or to segregate them. Some of the hot process equipment could be placed out of doors with only a protective roof.

The location of furnaces in separate wings rather than in a large single building will simplify the problem of supplying air f6r general ventilation. These wings may have high roof to provide better chimney effect for the removal of hot air over the furnaces. Hot process or area should be enclosed where conditioned air can be supplied.

Provide engineering Controls for general air movement, shielding of radiant heat sources and to reduce process heat, water vapour release and metabolic rate.

Set acceptable exposure times and allow recovery form body strain.

8.2 Insulation:

The insulation of furnaces and other heat producing equipment will not only reduce the amount of heat exposure but also result in the consequent saving in fuel consumption. If all the heat produced by a process is released into a. workroom and the heat production is constant, no amount of insulation around the process can reduce the heat exposure. The insulation will be of value only when heat produced has several avenues of escape, the dissipation into the workroom being only one of these. In such cases, a combination of insulation and exhaust or gravity ventilation will be quite effective.

To reduce solar heat radiation false ceiling, (double roofing) or painting the roof by heat reflecting surface or colour (e.g. white) is useful. Pipes, vessels and other hot surfaces should be insulated to reduce heat radiation from them.

8.3 Substitution:

If possible the hot process should be substituted by localised or more efficiently controlled method of heating. For example, cold riveting or spot welding instead of hot riveting and induction hardening instead of heat treatment.

8.4 Local Exhaust Ventilation :

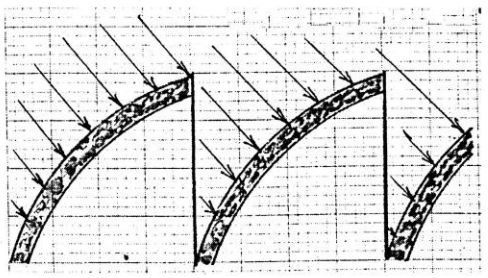
Another method of removing the heat from the source is by providing ventilated enclosures such as canopy or exhaust hoods by which natural convection column of heated air rises from a hot process environment This will minimise the temperature rise in the space around the hot process.

See foregoing part 7.3.2(2) for details.

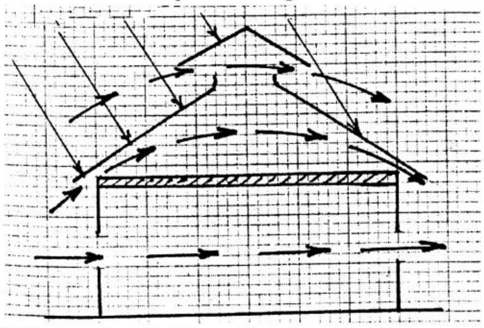
8.5 Control of Radiant Heat :

In some industries the frequency of very hot 'objects and surfaces such as furnaces, ovens, furnace stacks, molten material, hot ingots of metal, castings, and forging is such that the major environmental heat load is in the form of radiant heat which may be several times greater than the convective heat load. No amount of ventilation with or without air cooling will reduce the heat exposure since air temperature has no significant influence on the flow of radiant heat.

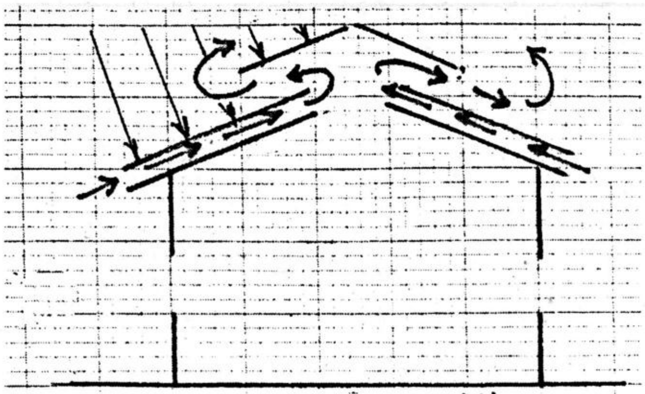
The only effective control is decreasing the amount of radiant heat impinging on the exposed workers. This can be accomplished by either lowering the surface temperature 'of the hot equipment (by insulation or by water cooling), or by radiation shielding. A shield is simply a sheet of material, opaque to the infra-red waves placed between a hot object and work surroundings. The shield should not contact the radiating surface and the presence of a ventilated air space between the hot object and the shield to avoid heating of the shield by conduction and to remove the heated air in between. Materials best suited for radiant heat shields are those with surfaces that maintain the high reflectivity for radiant heat and low emissive under plant conditions. Aluminium sheet has these properties. It is the most common material used for radiation shielding.



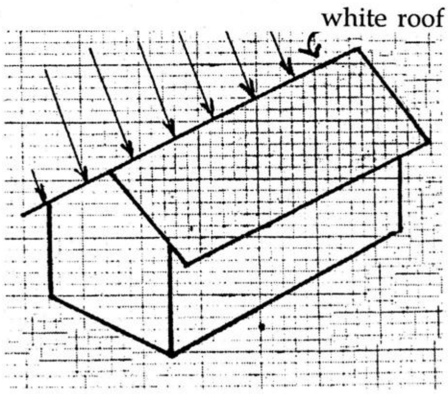
Insulated roof for protectiion against solar radiation



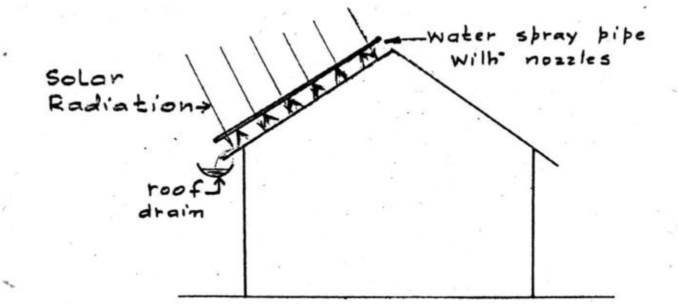
Pitched roof with false ceiling for protection against solar radiation



Double roof with ventilated air gap. Interior unaffected by solar radiation



Roof painted white reduces effect of solar radiation



Roof spraying process produces evaporation and cooling

Fig. 10.13 Control of Radiant heat.

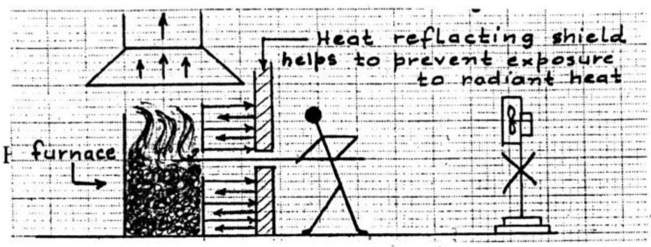


Fig. 10.14 No faning can reduce the effect of radiant heat from "Hot process"

Roofs of corrugated iron sheets or asbestos cement sheets get heated by sun in hot weather and act as a constant source of heat, the major portion of which is radiant heat. Control of this type of heat' exposure may be achieved by lowering the surface temperature of the roof by :

1. Insulating roof by providing a layer of material of low conductivity.
2. Shielding by the provision of a false roof or ceiling with sufficient air space ventilated to outside atmosphere.
3. White-washing or white painting the exterior surface of the roof.
4. Spraying of water intermittently over the roof to cool it by evaporation.
5. Openings and glazing in the walls and roof through which sun rays penetrate in summer should as far as practicable be screened.

8.6 Local Relief :

In certain situations when a general reduction of heat exposure throughout die plant is not otherwise feasible, relief may be provided locally, i.e. at the work place by surrounding the exposed worker with an acceptable thermal environment by providing positive ventilation. The following three methods may be employed depending on the work situations :

1. Providing a complete enclosure around the worker with a separate ventilation in order to'. maintain cooler working conditions. This may be in the form of air-conditioned control room, small shelter booth, or ventilated crane cab.
2. Surrounding the worker with a relatively cool atmosphere by a direct supply of air introduced at the working level or over a small area of the plant.
3. Directing a high velocity air stream at the worker when the air is capable of absorbing heat i.e. either its dry bulb temperature is reasonably lower than the body temperature or its humidity is low enough to allow evaporation of sweat.
4. Give a cup of cool palatable drinking water at 20 to 30 minutes.
5. Give training about heat stress and strain and their control measures.
6. Encourage consumption of salty foods if medically not restricted.
7. Permit self limitation of heat exposures and frequent rest intervals.

8.7 Personal Protective Equipment

In certain operations, such as glass drawing, blowing or enamelling, metal melting furnace etc., the workers may be required to work within reach of hot objects which may be at temperature of 800 °C (1472 'F) or higher and the time required for operation may reach 10 to 20 minutes. In such situations, protective clothing and protective shields of heat reflecting type can be used for controlling heat exposures.

The protective clothing is generally made of aluminised asbestos cloth usually backed up with felt or other insulating material. Aluminised fibre glass, aluminised cotton duck or aluminium sprayed, asbestos have also proved effective. The operator may be equipped with mitts, leggings, apron, jacket, helmet, and special arm sleeves according to specific operations. The protective clothing must not be very heavy and should be flexible enough to permit free movement. Only those parts of the body which are facing the hot objects need be covered. .

Pay attention on signs and symptoms of heat induced disorders and provide remedy.

9 TESTING AND MAINTENANCE OF VENTILATION SYSTEMS

This is most essential for the upkeep of all ventilation equipment. Fans and other equipment shall be so located that maximum fresh air intake or exhaust air outlet, accessibility for repair and maintenance and noise reduction are possible. In flammable areas fans of non-sparking construction and motors of flameproof construction are most desirable. They will be so placed ' that any explosion will not vent into the workroom. The ducts should be properly laid and connected air tight. Their easy inspection, replacement, repair and maintenance should be possible. The metal duct work should confirm to IS:655. Dampers will be provided where necessary.

The testing of ventilation system should Check

1. Volume flow rates (Q) at the supply and exhaust openings to meet the design specification.
2. The system is not causing excessive noise and vibration.
3. Designed air quality is maintained at all times.
4. Control measures if the toxicity of inside air is increased.
5. Outlets from factory premises do not cause air pollution for community.

See Part 4.3 for measurement of air velocity, volume flow rate, toxicity of air etc.

Intake (plenum) shafts to work as air inlet, ducts for carrying fresh or exhaust air, Humidifiers to maintain desired humidity. Air heater to heat air in cold period. Air ejector for exhaust of flammable or explosive gases and dusts from workrooms. Fans of various types (centrifugal, axial, propeller) to deliver or exhaust large volumes of air, and Motors are such ventilation equipment which need good installation, operation and maintenance.

Air cleaning equipment or collector such as Dust collector or De-dusting chamber to precipitate suspended dust, cyclone - a dust extractor wherein dust is separated from the cyclonically rotating dusted air by centrifugal force. Bag filter (house) to separate air depositing the fine dust particles on outside of the canvas. Oil filters for fine cleaning of the air in which dust concentration are up to 10-20 Inrr/m3 Paper filters to clean the plenum air from the fine dust and' Electrical precipitators to attract and collect airborne dust particles in electric field are also equally important for maintenance purpose.

Industrial ventilation is, thus, a complex installation which requires skilled and specially trained personnel for proper operation and maintenance. A maintenance book or register should be kept with each ventilation unit Instructions for startup, shutdown, maintenance, repair, operating parameters, nature of trouble and its elimination and trial runs should be recorded in the register. While testing a ventilation system, the fans should be checked for its efficiency, pressure and speed. Unguarded moving parts should not be touched.

Indian Standards useful for electrical safety are 732 and for fire safety 1646.

Personal protective equipment such as special clothing, goggles, safety shoes, gloves, hard hats, aprons, ear protection, respiratory or lung protection including various dust filters and gas masks, barrier creams and detergents should be checked before use, well maintained and kept effective.

All ventilating equipment should be checked periodically, bearings and various moving parts should be lubricated and all metal parts and air cleaning devices including filters should be checked regularly for dust deposition, choking, corrosion and protected by anti-corrosion paint.

Filters and heat transfer units should be regularly cleaned for their efficient use. Dust or condensed vapour in the system should be cleaned. The integrity back pressure and efficiency of the filters and cyclones should be checked.

The equipment shall be tested as mentioned below for rated air delivery.

As discussed earlier, ventilation is created by positive draft or exhaust of air. The fans normally used arc centrifugal (air leaves the impeller at right angles to its axis), axial flow or propeller type (air leaves the impeller parallel to its axis). As per requirement of the air movement (including make up air) the fan and motor capacities are selected. Testing is required to check this rated (expected) air volume Q in m^3 / min.. This flow may fall down because of wear and tear, lack of lubrication, corrosion, choking of air filters, ducting etc. Testing of air flow can reveal this fact and suggest the necessary replacement or maintenance.

The volume of inlet air (outside air by positive ventilation) is given by $Q = kAV$
where A = Area of intake opening of duct in n12 and V = Average velocity of air in m/min, measured by a calibrated 'anemometer', velocity meter and pivot tube. Co-efficient 'k' varies from 0.5 to 0.6 when air openings face wind and 0.25 to 0.35 when openings are at angle.

The volume of exhaust air can also be measured by the same formula and manner.

Ventilation due to convection effects arising from temperature difference between inside and outside is
given by $Q = 7A \sqrt{h}(t_i - t_0)$

where Q and A as stated earlier, h = vertical distance between inlets and outlets in mm, t = temperature of indoor air at the outlet in °C and t = temperature of outdoor air in ^oC.

Variation of air flow through filters (or grills) should not be more than ± 20% of the mean value.

Turbulent air flow at the working zone can be measured by Kata thermometer, heated thermo anemometer or properly calibrated thermocouple anemometer.

10 WORKED EXAMPLES

Static Pressure (SP) is created by gravity and modified by the fan. SP is felt in all directions within die duct and is measured in such a way that the flow of air does not effect the measurement.

If the end of the manometer probe is inserted facing directly into the air stream, the manometer.

Equation: TP = SP+VP
Volume flow rate Q = Vx A
Where, Q = volume flow rate, cuft/min. V = velocity, feet
per minute, A = area, sq.ft.

Example-1

The cross-sectional area of a duct is A = 2.445 sq.ft. The average velocity of air flowing in the duct is V = 3500 ft/min. at standard conditions (STP). Calculate the flow rate, Q.

Q = V x A
= 3500 ft/min x 2.445 sq.ft
= 8557.5 cuft/min

Example-2

The diameter D of a round duct -is 25 cm. The average velocity of air flowing in the duct is V = 21 mt/ sec at standard conditions (STP). Calculate the flow rate, Q.

$A = \pi D^2/4 = \pi\ (25cm)^2 - 4$
$= (0.25\ \text{meters})^2\ /4 = 0.0491$ sq.mts.
Q = V x A
= 21 mt / sec x 0.0491 sq.mts.
= 1.03 cu.mt. / sec

Velocity and Velocity Pressure (VP)

$V = 4005\ (VP/d)^{0.5}$ US units
$V = 4.043\ (VP/d)^{0.5}$ SI units

Where, V is velocity, VP is Velocity Pressure and D is Density correction factor

Example-3

The average Velocity Pressure of an air stream in a duct is VP = 1.00 inch w.g. Calculate the average velocity. (Assume STP, d = 1.0)

$V = 4005\ (VP/d)^{0.5}$
$V = 4005\ (1.00/1.00)^{0.5}$
V = 4005 ft/min

Settling Velocity (Vs)

$Vs = 0.0052\ (S.G.)\ D^2$ US Unit
$Vs = (26.4 \times 10^{-6})(S.G.)\ D^2$ SI Unit
Where SG = D = Diameter of particle

Example-4

What is the settling velocity of iron oxide fume of 1.0 micron diameter? S.G.=.6.6.

$Vs = 0.0052\ (S.G.)\ D^2$
$= 0.0052\ (6.6) \times 1.0^2$
= O.OSft/min

$Vs = (26.4 \times 10^{-6})(S.G.)\ D^2$
$Vs = (26.4xl0^{-6})\ (6.6)1.0^2$
= 0.00017 mt/sec

Hood Entry Loss

The hood entry loss, H is the sum total of all the losses from the hood face to the point of measurement in the duct.

He = K .VP.d

Where: H_e = Hood entry loss (US units: inch w.g., SI units: mm w.g.)

Example-5

Calculate the hood entry loss, if the duct velocity pressure VP = 18.5 mm w.g. and the hood static pressure

SP_h = 26.5 mm w.g.
$H_e = SP_h - VP$ = 26.5 mm - 18.5 mm = 8.0 mm w.g.

Fan

The Fan Total Pressure is often designated as FTP or TPF. FTP represents all energy requirements for moving air through-the ventilation system. FTP is calculated by adding the absolute values of the average total pressures found at the fan.

FTP = TP outlet - TP inlet
TP outlet = SP out+VP out
TP inlet =SPin+VPin
FTP =SPout+VPout-SPin-VPin
=SPout-SPin (if VP out is = VPin)

To size a motor one should find out air power (ap), brake power (bp), shaft power (sp) and rated power (rp).

Air horse power refers to the minimum amount of power to move a volume of air against the fan total pressure.

Ap = FTP. Q.d / f

Where

ap is air power (US unit: bhp and SI units =kW).

FTP is Fan Total Pressure (US units = inches w.g.

SI units = mm w.g.) w.g. = Water gauge
d is the density correction factor
f is a unitless factor (US units = 6356 and SI units 102.2)
bp = ap/eff -FTP. Q.d /f.eff.

Example-6

What is the required power to install local exaust ventilation and what rated power motor should be selected from following data ?

	US unit	SI unit
FTP	5.0 inch w.g.	127 mm w.g.
Volume rate	Q 12000 s.cuft/m	5.664 s.curnt/sec
Eff	0.60	0.60
Kdl	1.10	1.10
STP d	1	1
f	6356	102.2

Note : In volume rate s denotes standard condition

$$\text{SP(Shaft Power)} = \frac{\text{FTP x Q x Kdl x d}}{\text{f x eff}}$$

$$= \frac{5.0 \text{ x } 12000 \text{ x } 1.10 \text{ x } 1}{6356 \text{ x } 0.6}$$

$$= \quad 17.3 \text{ HP} \qquad \text{(US Unit)}$$

$$\text{SP (Shaft Power)} = \frac{FTP \times Q \times Kdl \times d}{f \times eff}$$

$$= \frac{127 \times 5.664 \times 1.10 \times 1}{102.2 \times 0.6}$$

$$= \quad 12.9 \text{ KW} \qquad \text{(SI Unit)}$$

Example-7 (Heat Stress Calculation)

An acclimatized worker with summer work uniform (ACGIH clothing correction factor-O) is exposed to heat at various locations of foundry during different processes as shown in following table. An Industrial Hygienist found following results of measured parameters by WBGT (heat stress monitor) meter. The worker was engaged in heavy work with 50% of work and 50% of rest. Calculate his average heat stress exposure and state whether it is within permissible limit or not.

Processes	Result in WBGT °C	Duration of Exposure in Minutes
Charging of metal in Cupola furnace	40°C	20
Observing and working near Furnace	48°C	120
Unloading of molten metal in ladle	65°C	20
Fettling Operation	45°C	50

$$\text{Average WBQT} = \frac{(WBGT_1)\ (t_1) + (WBGT_2)\ (t_2) + \ldots.. + (WBGT_n)\ (t_n)}{t_1 + t_2 + \ldots. + t_2}$$

Average WBGT = (40 x 20) +(48 x 120) +(65 x 20) +(45 x 50)/210

Average WBGT = (800) + (5760) + (1300) + (2250) / 210 Average WBGT = 48.14° C

Considering the correction factor of clothing WBGT = 48.14 + 0 = 48.14° C

Considering factors of acclimatizing, percentage of work & rest and heavy work the exposure limit recommended by ACGIH (2006) is 28.5° C

In present case, worker is exposed to (48.14° C) more than the recommend value of heat exposure (28.5° C).

Therefore, control measures are necessary to bring down the exposure level from 48.14° C to 28.5° C or less.

E X E R C I S E

1. Explain, State, Mention or Discuss:

1. The purpose or objective of ventilation and heat control.
2. Statutory provisions regarding ventilation.
3. Parameters of thermal environment and methods of their measurement.
4. Different factors affecting heat stress and measures to control them.

5. Heat balance equation and factors affecting it
6. Effects of hot and humid environment on safety and efficiency.
7. The concept of WBGT and its usefulness.
8. Effects of cold stress, factors increasing it and factors decreasing it.
9. Health disorders in hot environment.
10. Safety problems due to increased temperature.
11. Engineering controls to reduce effects of parameters of Heat balance equation.
12. Methods of personal management (administrative efforts) to control heat stress.
13. Following terms:
    (1) Dry & wet bulb temperature (2) Capture Velocity (3) Due point (4) Dilution ventilation (5) Exhaust of air (6) Effective temperature (7) Local exhaust ventilation (8) Plenum ventilation (9) Evaporative cooling (10) Roof ventilation (II) Emergency ventilation (12) Air conditioning ~ (13) Spray booths (14) Local relief (15) Insulation OR Substitution (16) Comfort zone (17) Dust collectors (18) Hood (19) Air cleaner (20) Dust.
14. Factors that help acclimatization.
15. Design factors of a ventilation system.
16. Mechanical ventilation for Building .and process (contaminants) control.
17. Different types of ventilation for a factory building.
18. Points of consideration while designing a hood for local exhaust ventilation.
19. Ventilation for special operations.
20. Maintenance aspects of ventilation systems.
21. Various types, of roof for a factory building and methods to improve natural ventilation. Explain by sketch.
22. Indices for heat and cold stresses.

2. Write short notes on :

1. Effects of good ventilation.
2. Effects of bad (poor) ventilation.
3. Important Indian standard on code of practice for Industrial ventilation.
4. Types of instruments to measure air movement.
5. Pilot static tube.
6. Effects of heat on skin.
7. Reasons of discomfort.
8. Factors decreasing ability to with stand high temperatures.
9. Heat disorders on human body.
10. Oxford Index OR Wind chill Index.
11. Predicted Four Hourly sweat rate.
12. Protective measures against cold stress.
13. Causes of temperature rise in industry.
14. Acclimatisation.
15. Requirement of fresh air.
16. Principles and selection criteria for air cleaning devices.
17. Classification of ventilation systems.
18. Natural ventilation 05 Roofed ventilation.
19. Cowl type roof ventilation.
20. Local exhaust ventilation and its design aspects.
21. Air conditioning and hazards associated with it.
22. Control of heat exposures at source.
23. Control 'of Radiant heat.
24. PPE while working in hot processes.
25. Points of testing of a ventilation system.

26. Physiological effects of 'heat on factory workers.

3. **Explain the difference between :**
   1. Good and bad ventilation.
   2. Dry bulb thermometer and Glob thermometer.
   3. Hygrometer and hygrograph.
   4. Vane anemometer and cup anemometer.
   5. Kata thermometer and Glob thermometer.
   6. Pressure tube manometer.
   7. Smoke tube and Gas defection tube.
   8. Heat stress and cold stress.
   9. Heat stress and heat strain.
   10. Effective temperature (ET) and corrected effective temperature (CET).
   11. Wind chill Index and wind chill cooling rate.
   12. Different methods for control of heat stress.
   13. Positive & Negative ventilation.
   14. Absolute & Relative humanity.
   15. General ventilation and Natural ventilation.
   16. Make up air and Air changes.
   17. Comfort ventilation and Air conditioning.
   18. Insulation & substitution to control heat exposures.
   19. Segregation & Enclosure.
   20. Dust suppression & dust prevention.
   21. Air distribution and Air conditioning.
   22. Cyclone separator & Fabric filter.
   23. Exhaust ventilation & Plenum ventilation.

4. **Comment on the following explaining whether it is true or not**
   1. Human body (core) temperature varies and equals the environmental temperature.
   2. Heat stress is affected by climatic factors but not affected by non-climatic factors.
   3. Acclimatisation helps to tolerate heat stress.
   4. Cotton clothing are most comfortable for decreasing heat stress.
   5. Good ventilation increases comfort and bad ventilation decreases it.
   6. Temperature alone is not a good indicator of comfortable conditions.
   7. Toxic effect of chemical increases as temperature increases.
   8. Natural ventilation is preferable than mechanical ventilation.

CHAPTER – 11

Electrical Safety

THEME

1 ELECTRICITY, ITS USEFULNESS AND HAZARDS

1.1 Usefulness of Electricity :

Electricity and electronics are not much old sciences. Till 1890 physicists were asking What is Electricity? With the beginning of 20th century, electricity entered and today it has changed the whole industrial, economic and social picture. Faster and mass production and advancement of life could .not have been possible without electric power which has become the major source of prime movers for most of the machines. Electricity has illuminated many areas of life viz. industrialisation, light, sound, heating, cooling, education, computer, transportation and numerous essential human services. Its domestic uses are day by day increasing. A variety of kitchen appliances and other electrical equipment have touched almost every corner of our modern life. But it is to be handled with care, because its contact with human body is dangerous and proves fatal if not properly controlled by engineering and manual precautions.

Demand of electricity is ever increasing because of its growing need for industrial mass production, urban and rural electrification, domestic and agricultural use, pump-sets demand for water etc. In 1995-96 total 380 and in 1996-97 total 394.5 thousand million units (kwh) electricity was produced. During 1997-2002, in the 9th Plan, an increase of 57734.7 MW was recommended. 25 private power projects of 141000 MW capacity were sanctioned.

1.2 Accidents & Hazards :

Accident tables T 5.7, 5.8, 5.20 and 5.22 given in Chapter-5 reveal that in India and Gujarat, electrical fatal accidents are @ 2 to 7% of the total accidents. Mode of fatal accidents due to electricity is increasing. With the constant increase of per capita consumption of electricity, the chances of electrical accidents may also increase. It is also important to note that the accidents on low voltage (230 V) working are more than that on high voltage working, and untrained people are more involved than the trained people.

At **Uphar cinema hall** in Delhi, 59 died in fire due to electricity in 1997. Therefore 107 cinema halls, restaurants and banquet halls were given notices on 2-7-97 by the Delhi Vidyut Board for various deviations from the 17 electrical safety conditions. As per Delhi Fire Service's report, 70% of more than 2000 fires during that period had occurred due to short circuits (News 101-98).

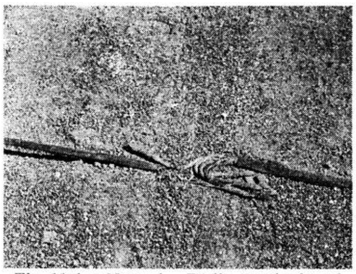

Fig 11.1 : Hazard - Badly crushed and tapped electric wires lying on the road

Loose Electric wires or cables lying on the road are crushed by moving vehicles. Allowing them in tapped condition create hazard. Such condition should be avoided See Fig. 11.1

One old Pennsylvania study gives the following break-up for electrical accidents.

	Cause	%
1.	Overloading, Poor arranging.	36
2.	Unsafe or improper use of equipment.	31
3.	Working on moving or dangerous equipment.	16
4.	Unnecessray exposure to danger.	10
5.	Not using the personal protective equipment.	5
6.	Improper starting or stopping.	2

A study of the electrical equipment industry in Germany shows accident to body sites as shown in figure 11.2:

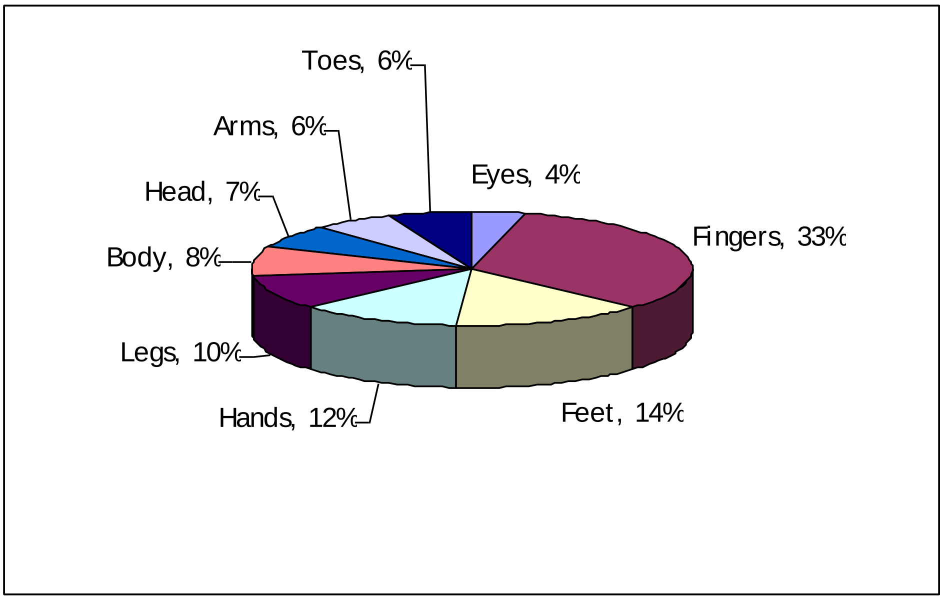

Fig 11.2 : Body site injuries

This percentage is variable, but it indicates the areas of hazards need to be controlled. Main electrical hazards are:

1. Electric Shock.
2. Electric Burns.
3. Fire and Explosion.
4. Hazards due to Electric Welding and Cutting
5. Hazards due to static electricity.
6. Fall of lightening from the sky.

Shock and burns are injury from direct contact. They cause accidents of three types (1) Hold-on type (2) Ventricular fibrillation and (3) Respiratory arrest.

Injuries are possible without current flowing through body, e.g. burns due to electric arcs, radiation, electromagnetic field, falling or injury due to sudden starting of machine, equipment etc.

Main protections are proper fuses, switchgears, circuit breakers, earthings and bonding. Such electrical safety precautions are highly needed to prevent accidents .due to electrical hazards.

2 STATUTORY PROVISIONS

2.1 Factories Act and Rules:

However the Factories Act and Rules do not contain any details of electrical safety and therefore no effective implementation of the electrical safety is possible through this Act. No prosecution is possible for such purely electrical causes except u/s 7A.. Only section 36 A speaks of portable electric light of less than 24 V and section 37 requires effective enclosure to sources of ignition. Which includes flame proof electric fittings.

Rule 86 of the Karnataka Factories Rules, 1969 provides as under:

"Electricity - (1) No electric installation shall be provided in factory, so as to be dangerous to human life or safety in the opinion of the Inspector. Provided that the Inspector may issue an order in writing, specifying the arrangements necessary for adequate safety, in addition to what is provided under the provisions of Indian Electricity Act or Rules there under. (2) In the main switch board or switch boards of factories, there shall be provided earth leakage and overload relays. The earth leakage relay shall be so provided that the leakage current shall not cause electrocution or other hazard."

These provisions are insufficient to scrub violations of electrical safety rules. This may be due to the separate Electricity Act and Rules as follows: 2.2 Electricity Act and Rules:

Electricity Act 2003 and Rules' 1956 &2005 require many safety aspects. Under these rules the consumer is responsible to maintain his electrical installation fully safe and certified. An inspection by Electrical Inspector is also required. For details see Part 2 of Chapter-28.

3 INDIAN STANDARDS

3.1 List of Standards.

Many IS are available on electrical safety such as : Current passing through human body, effects 8437, Drilling machines, flameproof, for use in mines 9192, fuses 2086, 1884, 3106, transformers. Safety 1416, lifts dimensions 3534, lighting fittings - flameproof 2206 (Part I to 4), safety requirements for luminaries 1913/ waterproof 3528, water tight 3553, power connector; 5561, shock-equipment for protection against 9409, strength test for solid insulating material 2584, electrical accessories 5133, apparatus and circuit intrinsically safe 5780, control devices operating electrical apparatus 7118, flameproof enclosures -2148, for use in explosive gas atmosphere 7693, spark test apparatus for 9166, testing 649, appliances-household, safety requirement 302, connections for lighting fittings, screwless 6585, for explosive atmosphere 8239, 8240 8241, 4691, 7389, of machine tool 1356, installation - classification of hazardous areas 5571, 5572, sand filled protection of electrical equipment 7724, safe magnet telephones for use in hazardous atmosphere 6539, safety for rectifier equipment 6619, insulating materials 8765, 4249, 6792, environmental tests 8999, 9000, layout in residential buildings 4648, measuring instruments for explosive gas atmosphere 8945, relays 3842, 5834, 3231, resistance-material test 3635, power stations - fire safety 3034, wiring 732, 1653, 3837, 2669, dust-proof electric lighting fittings 4012, dust-tight electric lighting fittings 4013, dust-tight ignition proof enclosures 11005, flash back (flame) arrester 11006, lightning arrester 4850 (withdrawn), building protection against lighting 2309, static electricity, guide for control 7689, electro heat installation, safety requirement 9080, guide for safety procedures and practices in electrical work 5216, danger notice plates 2551, earthing, code of practice 3043, indicating instruments 1248, 3107, 9319, induction motors 900, starters 5124, switches push button 4794, heavy duty 4047, electrical equipment for use in medical practice 8607 (Part I to 8), warning symbols for dangerous voltages 8923, safety requirement for measuring instruments 9249, safety requirements for refrigerators, food freezers 10542, building for installation of electric apparatus for gas atmosphere, rubber mats 5424, rubber gloves 4770, safety for audio amplifiers 1301, electric wiring in hospitals 7733, wiring voltage exceeding 650 volts 2274, not exceeding 650 volts 732, overhead power and telecommunication lines concrete poles 7321 and portable methanometer (electrical type) 9937.

IS:5216 - Guide for Safety Procedures and Practices in Electric Work - Part I : General and Part 2 : Life Saving Techniques must be followed strictly. A form of permit-to-work and special instructions while working with such permit are given in Part 1. Use of IS for hazardous area classification, equipment to be used in such area and earthing practice are also recommended.

SP 30 National Electric Code compiling many IS on electrotechnology, and SP 31 on treatment for electric shock are most useful for safety purpose. Other special publication SP 39 on low-voltage systems, SP 48 on electric irons, SP 49 on electric water heaters, SP 50 on electric radiators and SP 51 on electric stoves are also useful.

3.2 National Electric Code (NEC) :

This Code was adopted by the Indian Standards Institution on 15-6-84 and was first published in - August 1985. Its number is SP:30-1984.

The object as stated in the Code, is to complement the Indian Electricity Rules 1956 by way of elaborating as well as recommending practices to comply with their requirements. This Code is to provide information in a consolidated form to electrical engineers and contractors in the country who are concerned with the design and operation of electrical installations. The subject matter is divided into the following seven parts :

1. General and Common Aspects.
2. Electrical Installation in Standby Generating Stations and Substations.
3. Electrical Installations in Non-industrial buildings.
4. Electrical Installations in Industrial Buildings.
5. Outdoor Installations.
6. Electrical Installations in Agriculture Premises, and
7. Electrical Installations in Hazardous areas.

The information of each type of installation is further classified as under:

A. Assessment of the general characteristics of the occupancy from the point of view of the electrical installation therein.
B. Heavy current installation in the occupancy.
C Light current installation in the occupancy.
D. Specific requirement for protection and safety.

The Code lists various Indian Standards incorporated in the subject. As a safety aspect it also suggests permit-to-work system, safety instructions, safety practices, use of safety posters and treatment for electric shock. It provides details for terminology, principles, practices, selection of equipment, erection, testing, earthing, wiring, short circuiting, fire alarm system, protection, classification, safety etc.

As fundamental principles, the Code insists for-

1. Conformity with Indian Electricity Rules, Materials conforming to IS and good workmanship.
2. Co-ordination and co-operation between personnel.
3. Safe distance from electric lines.
4. Lighting, ventilation, heat insulation, lifts and location and space for electrical equipment.
5. Protection of persons, livestock and property and proper functioning of electrical installation.
6. Safety against shock currents and excessive temperatures.
7. Protection against direct and indirect contact, thermal effect, overcurrent, fault current and overvoltage.
8. Cross section of conductors, type of wiring, protective equipment, emergency control, disconnecting devices etc. Protective equipment should operate at values of current, voltage and time suitably related to the type of circuit and danger.

National Electric Code and Life Safety Code from National Fire Protection Association (NFPA), USA is also available on the subject.

3.3 TAC Regulations for Electrical System:

Above regulations published by the Tariff Advisory Committee (General Insurance), Bombay has been framed to ensure maximum safety to the insured property from the risk of fire/explosion due to the use of electricity. To that extent, these rules are different from the Electricity Rules 1956 and other statutory provisions. It includes requisite information from some Indian Standards and gives in its Appendix E a list of some useful IS.

These regulations apply to the entire electrical system from the point of supply to its use and covers all power equipment, switchboard, power distribution and motor control gear, transformer substation, earth connections, wiring, lighting fittings and accessories, electrical equipment and apparatus and requirements of specific occupancies like godowns, strong rooms, lifts, petrol stations, hazardous locations, machine rooms, high rise buildings etc. and testing.

The rules are comprehensive and in case of doubt it is suggested to refer the TAC, Bombay.

4 EFFECTS OF ELECTRICAL PARAMETERS ON HUMAN BODY

4.1 Physiology of Electric Shocks:

First major hazard due to electricity is shock to a person. It is the current, not voltage that causes physiological damage. But the current (1), voltage (E) and resistance (R> are inter-related by Ohm's Law, E=IR, and therefore all these three factors are important to control each other. Power (W) is W=EI and electrical energy is the product of power and time i.e. EFT and is given by a Joule (I Joule=l ampere at I volt for I second), I Joule/Sec is I watt and the practical unit for energy is the kilowatt-hour and .1 KWH is equal to 1.34 HP, the Horse Power, an another unit of electrical energy.

The blood is good conductor of electricity, but the skin is highly resistive. Unless the skin is punctured, no more current will flow through the body. Body resistance of each person is variable, therefore effect on them is also variable. Upto 10 mA, current can be barred with pain, but at 30 mA chest muscles do not work, breathing stops and death may occur. 250 mA causes complete death. Thus a leakage of 0.25 ampere is dangerous for human life. Sometimes after-effects are more severe than the actual shock or burn.

Electric Shock is an effect of a current flowing through nerves, muscles, heart or organs of a body. Electric shock is sudden and accidental stimulation of the body's nervous system by electric current which flows due to voltage difference.

The current may be DC (Direct Current) or AC (Alternating Current). DC may maintain involuntary grip on the live conductor which prolongs the current flow. Therefore the victim needs to be separated by a non-metallic rod or device. More DC is required than AC to cause the same effect. AC produces fibrillation every cycle whereas DC produces only once.

Low current disturbs body rhythm, sometimes stops heart if time duration prolongs but high current causes electric burns and sometimes death.

Shock may happen due to:

1. Contact with bare live conductor.
2. Removal of insulation of a conductor and its contact.
3. Short circuit due to sudden failure and the short circuit current not going to earth but flowing through human body.

4. Static charge on equipment discharges through human body.
5. Lightening.

The severity of shock depends on current value and the time of its passing through the body. 10 mA current can flow 5 seconds through the body without danger, while 100 mA flowing even for I second could be fatal. It also depends on type of current (AC or DC)/ frequency, path of the current through body i.e. passing nearby the heart or other nerve centre.

Personal sensitivity to electric shock varies from person to person. It depends on age, sex, heart and wetting of skin which varies the resistance of body. But as the supply voltage and frequency are same throughout the country (e.g230 V, 50 c/s) and normal body resistance of a 50 kg or 60 kg man is also same for the equal' condition, the current values are determined (by experiments) to find their effects on body. These are stated in tables in Part 4.2

A woman's body is more susceptible to electric Tents and the same effects may be produced with @ 60% the current required in a man.

At 30000 to 100000 c/s frequency the danger is less. Direct current of 0.5 A and above, and a surge of oscillatory energy from 10"to 30 watt-seconds may prove dangerous. For 50 c/s AC current, dangerous limit of voltage are 24 V for children and 60 V for adults. In wet 6ituation it is decreased (Statutory limit is 24 V).

The magnitude of the current flowing through the body depends on the applied voltage (current is directly proportional to voltage for the same resistance), the resistance of the path through body (current is inversely proportional to resistance for the same voltage) and the resistance in turn depends upon the area of the skin in contact with electrically live object, the moisture content of the skin (moist skin has low resistance, allows high current and is more dangerous ' than dry skin) and again the voltage. The resistance of body falls as the voltage or current is increased. See Table 11.4.

Temperature & humidity increase perspiration, which makes the body wet. This decreases resistance, allows higher current and is more serious condition.

Oxygen and Carbon Dioxide in air also affect. When oxygen is less or Carbon Dioxide is high in the air, body resistance reduces and the condition is like wet skin i.e. dangerous. The electrical hazards for welders increase for this reason.

Type of flooring, insulated, uninsulated, dry or wet has direct effect. Insulated and dry floor is safer than the uninsulated (conductive) or wet floor.

Position of body parts in the electric circuit through body is also important. If both the hands or both the legs touch live conductor, the effect is higher. The most dangerous condition is that of passing the current through heart.

Effect on heart is serious. 20 to 50 mA current passing through heart stops the heart so long as the current flows. Impurity of blood increases as the heart is not working. If this condition lasts for 5 minutes or n\ore, irreversible damage is caused to the brain (as oxygen is not reached there with the fresh blood) which may prove fatal. If the current is interrupted before that and the artificial respiration is promptly given to the heart, the patient will mostly recover.

If the current is increased 80 to 500 mA, the heart beat will stop and every fibre of it will contract haphazardly causing fibrillation. This will stop the entire blood circulation. Even a very short period of O.I second can cause this condition, and if the current is stopped after O.I second, the heart will never recover and death results after a few minutes. But it is possible to defibrillate the heart by using a device known as defibrillator. By this device a counter shock is given to the heart which reverts the heart muscles to their normal shape. However such device is available in the hospitals and the time factor is important to reach there.

Electric burns are caused due to high current flowing through body. Higher currents cause electric burns (joule burn, internal or flash over or thermal burn, external) and damage the nervous system. Electric burns internally heat the body (not ,visible from outside) and are curable by medical treatment. Due to high voltage and heavy current, sparking takes place and cloths also burn. This causes thermal burns and if they are extensive, the victim may die within few days.

According to Joule's law the heat generated is proportional to PRT, where I, R and T are current, resistance and time respectively. Burning takes place due to heat generated.

When human body, acting as earthed conductor, comes nearer to a high voltage conductor, the air insulation between them breaks down and a spark is developed between the two. Then current passes through the body to the earth causing flash burn.

In addition to flashing distance, flash burns can also be caused by heavy short circuiting or opening of an isolator carrying heavy load current.

For degree and percentage of electric burns see Part - 9 of Chapter - 26.

4.2 Effects of Amperages :

Following IS are most relevant:

IS:8437 Guide on effects of current passing through the human body :
Part -1 General aspects
Part -2 Special aspects

Effects of electric current on human body are summarised in Tables 11.1 to 11.3.

Table 11.1 : Current Range and Effect on a 68 Kg man

Current (50 Hz or c/s)	Physiological Phenomenon	Feeling or Lethal incidence
1 mA	None	Imperceptible
1 mA	Perception threshold	
1-3 mA		Mild sensation
3-10 mA		Painful sensation
10 mA	Paralysis threshold of arm	Cannot release hand grip, if no grip, victim may be thrown clear (may progress to higher current and be fatal).
30 mA	Fibrillation threshold 0.5 percent	Stoppage of breathing (frequently fatal)
75 mA	Fibrillation threshold 99.5 percent (5 second exposure)	Heart action discoordinated (probably fatal)
250 mA	Fibrillation threshold 99.5 percent (5 second	Heart and blood circulation may stop (usually fatal)

	exposure)	
4 A	Heart paralysis threshold (no fill fibrillation)	Heart stops for duration of current passage. For short shocks, may re-start on interruption of current (usually not fatal from heart dysfunction).
5 A	Tissue burning	Not fatal unless vital organs are burned.

Table 11.2 : Effects of DC and AC (current) on human body.

Current in mA			Effect
DC	**AC 50 Hz**	**Ac 10000 Hz**	
0-5	0-1	0-9	No sensation
6-55	1-8	10-55	Mild stock
60-80	9-15	60-80	Painful shock and hand unable to let go of live parts in case of AC
80-100	16-20	80-100	Some loss of muscular control
110-350	20-45		Severe shock and loss of muscular control
400-800	50-100		Possible heart failure (ventricular fibrillation)
>800	>100		Usually fatal
>1600	>200		Severe burns, severe fibrillation and death.

Table 11.3 : Effect of Electric Current on Men and Women

Current in mA						Effect
DC		**50 Hz AC**		**10000 Hz AC**		
Men	**Women**	**Men**	**Women**	**Men**	**Women**	
1	0.6	0.4	0.3	7	5	Slight sensation on hand
5.2	3.5	1.1	0.7	12	8	Perception threshold
9	6	1.8	1.2	17	11	Shock not painful, muscular control not lost
69	41	9	6	55	37	Shock-painful, muscular
76	51	16	10.5	75	50	Shock-painful, let-go threshold
90	60	23	15	94	63	Shock painful and severe, muscular contractions, breathing difficult.
500	500	100	100	-	-	Shock, ventricular fibrillation from 3 seconds
-	-	165 t	165 t	-	-	Short shock lasting ‘t’ seconds
50	50	13.6	13.6	-	-	High Voltage Surges
Energy in watt-seconds or joules						

Note : The figures are indicative and not absolute.

If a person gets electric shock and heart beat is not found, immediate remedy is an artificial respiration (see part-8 of Chapter-26) or resuscitation (CPR) to the person till he revives or death is diagnosed by a doctor. Minimum time should be elapsed before starting such respiration for possibility of success. This is indicated as under:

Time in Min	Possibility of Success
0-1	Best

1-3	Good
3-5	Fair
5-20	Poor

Therefore it is always advisable to give first-aid training including that of artificial respiration, to the maximum workers. Sec.45 & III-A under the Factories Act, require such training. See Part 8 of Chapter-26.

4.3 Effects of Voltages :

For our 50 c/s electric supply, main danger limits of voltage are :

24 volts for children, and
60 volts for adults

In wet condition', these values decrease and depend on other factors also.

At 50 c/s (Hz), dry condition, the calculated electrical characteristics of human body are given in Table 11.4.

Table 11.4 : Electrical Parameters of Human body at 50 Hz, Dry Condition.

V volt	R ohm	I = V/R mA
12.5	16500	0.8
31.3	11000	2.84
62.5	6240	10
125	3530	35
250	2000	125
500	1130	443
1000	640	1560
2000	362	5525

This table indicates that as voltage increases, body resistance decreases and current increases. Body resistance becomes practically zero at high voltages.

Approximate threshold shock voltages at 50 c/s are as under:

Threshold of feeling	10 to 12 V
Threshold of pain	15 V
Threshold of severe pain	20 V
Threshold of hold-on	20 to 25 V
Threshold of death	40 to 50 V
Range of fibrillation	60 to 2000 V

4.4 Resistance of Skin :

Skin resistance for dry and wet condition are , shown in Table-11.5.

Table 11.5 : Human Resistance for various skin-contact conditions

Condition (Area to Suit)	Resistance, ohms	
	Dry	Wet
Skin	100-600 K	1 K
Finger touch	40 K-1 M	4-15 K
Hand holding wire	15-50 K	3-6 K
Finger-thumb grasp	10-30 K	2-5 K
Hand holding pliers	5-10 K	1-3 K
Palm touch	3-8 K	1-2 K
Hand around 1.5 inch pipe (or drill handle)	1-3 K	0.5-1.5 K
Two hands around 1.5 inch pipe	0.5- 1.5 K	250-750
Hand to Foot	400-600	
Hand immersed	-	200-750
Foot immersed	-	100-300
Human body, internal, excluding skin ohms	-	200-1000
Ear to Ear	100	

K= Kilo ohms M=Megaohms

Courtesy : Konwenlioven & Milnor

For example, dry skin of 100 kilo ohms resistance allows for 230 V mains,

$$I = \frac{E}{R} = \frac{230}{100000} \times 1000 = 2.3 \text{ mA current}$$

But when it is wet, it offers I kilo ohms resistance and allows

$$I = \frac{E}{R} = \frac{230}{1000} \times 1000 = 230 \text{ mA current}$$

i.e. 100 times more current.

Body resistance varies considerably from dry skin (hand) to damp skin (hand) and from low voltage (24 V) to mains voltage (230 V).

It is safe to assume a value of 500 ohms for dry work places and 200 ohms (or less) for persons working in wet places. Body resistance is practically zero at high voltages.

For females an4 children, the value of body resistance should be taken as half of that given in Table-11.5, and for DC the values of resistance should be considered 4 times that of AC for the same voltages.

4.5 Resistance of Materials :

Resistance values for equal areas (130 cm^2) c various materials are as under :

Material	Resistance, ohms
Rubber gloves or soles	More than 20 M
Dry concrete above grade	1-5 M
Dry concrete on grade	0.2-1 M

Leather sole, dry, including foot	0.1-0.5 M
Leather sole, damp, including foot	5 K- 20 K
Wet concrete on grade	1 K- 5 K

Note : K = Kilo ohms, M = Mega ohms.

4.6 Safe Distance from Electric Lines :

It is obvious that overhead electric lines should not be allowed in a place where the public or public vehicles have to pass through for most of the time and not at such a low or unsafe distance (clearance above ground) so that chances of touching the lines may increase. Therefore some minimum safe distance from lines are necessary.

Rules 77 to 80 of the Indian Electricity Rules, 1956 provide safety distances as given in Table 11.6.

Table 11.6: Safely Distances of Overhead Lines

Position of Lines		Minimum Distance Ft	Mt
Across the street :			
	Medium voltage lines	19	5.8
	High Voltage lines	20	6.1
Along the Street :			
	Low & Medium voltage lines	18	5.5
	High Voltage lines	19	5.8
Elsewhere :			
	Up to 11 KV lines, bare	15	4.6
	Up to 11 KV lines, insulated	13	4.0
	Above 11 KV lines,	17	5.2
	Above 33 KV lines,	17+1 For every 35 KV or part thereof	5.2+0.3 For every 33 KV or part thereof
Above 33 KV lines but across or along the street		20	6.1
Crossing the tramway or trolley wires :		Distance above the trolley wire	
Low & medium voltage lines		4	1.2
If the wire is insulated			
Up to 11 KV lines		6	1.8
Above 11 KV lines		8	2.5
Extra high voltage lines		10	3.0
Passing above, adjacent or terminating on buildings :			
(a)	Low & medium voltage lines -	10	3.0
	Vertical clearance	8	2.5
	Horizontal clearance	4	1.2
	For less clearance the wire should be insulated		
(b)	High & extra high voltage lines -		
	Vertical clearance :		
	Up to 33 KV Lines	12	3.7

	Above 33 KV Lines	12+1 For every 33 KV or path thereof	3.7+0.3
	Horizontal clearance :		
	Up to 11 KV lines	4	1.2
	Above 11 KV & up to 33 KV lines	6	2.0
	Above 33 KV lines	6+1 For every 33 KV or part thereof	2.0+0.3

Note : In above table, meaning of voltage range u/i 2fav) is as under :

Low voltage	Up to 250 V
Medium voltage	Up to 650 V
High voltage	Up to 33 KV
Extra high voltage	Above 33 KV

Where an overhead line crosses or is in proximity to another overhead line, minimum clearances between them are prescribed u/r 87(3) and given in Table-11.7

Table 11.7 : Clearances in metres between lines crossing each other

System Voltage	11-66 KV	110-132 KV	220 KV	400 KV	800 KV
Low & medium	2.44	3.05	4.58	5.49	7.94
11-66 KV	2.44	3.05	4.58	5.49	7.94
110-132 KV	3.05	3.05	4.58	5.49	7.94
220 KV	4.58	4.58	4.58	5.49	7.94
400 KV	5.49	5.49	5.49	5.49	7.94
800 KV	7.94	7.94	7.94	7.94	7.94

Minimum clearance should be maintained for are conductors or live parts or any apparatus in Outdoor sub-station, excluding overhead lines as given in Table-11.8 [Rule 64(2)(a)(ii)].

Table 11.8 : Minimum Clearance in meters

Highest System Voltage in KV not exceeding Ground clearance of 1000 mts.	Safety working clearance (mts.)
12	2.6
36	2.8
72.58	3.1
145	3.7
245	4.3
420	6.4
800	10.3

Note : A correction factor of 1.25% per 100 mtr. is to be applied for increasing clearance above 1000 mtr. and upto 3000 mtr.

Guarding arrangement shall be provided to guard against the possibility of lines coming into contact with each other. Every guard wire shall be earned at each point where electricity is broken.

Rules 79 to 88 of the Indian Electricity Rules, 1956 are also relevant.

Safety distances from high voltage lines are as under -

Line voltage - Horizontal distances on both the sides form the centre line of the tower or H frame.
66 KV > 9.5 mt
132 KV > 13.5 mt
220 KV r 17.5 mt

5 SAFETY MEASURES FOR ELECTRIC WORK

Statutory measures are already mentioned in foregoing Part-2 which must always be followed with the help of IS mentioned in Part-3 above.

Some general and main safety measures are stated below:

5.1 General Safety Measures :

They include

1. Proper earthing and double earthing. General earthing for big power station, upto 0.5 ohm,

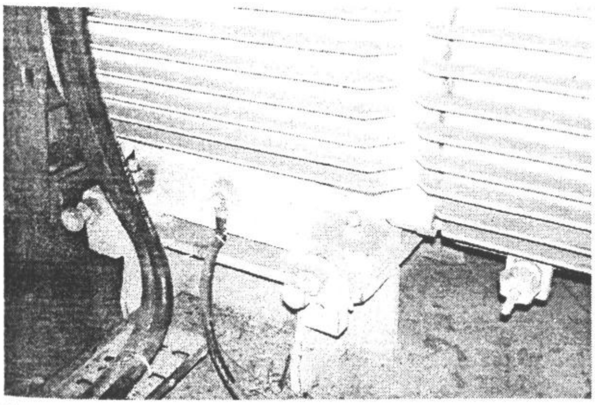

Fig 11.3 : Properly earthed electric motor.

   big substation 1 ohm, small substation 2 ohm and tower and other places up to 8 ohms. Due to minimum earthing resistance, leakage current passes through it and not through a person. The earthing should be inspected, tested and maintained properly. There should be a regular practice to check earthing. Minimum voltage between ground and the earthwire should be 30 V.
2. Use of approved insulated tools, rubber mats, shockproof gloves and boots, tester, fuse puller or tong, D.O. rod, discharge rod, safety belt, hand lamp, wooden or insulated ladder and not wearing metal ring, chain etc.
3. Switches on the live line. Fused switches and air-current breaks should be used.
4. Avoid temporary wiring. Avoid hurry and chance taking. Avoid left hand touching.
5. Employ qualified and trained electrician.
6. Low voltage (24 V AC or 110V DC) in hazardous area.
7. Good insulated and tested wiring.
8. Isolation of machine/equipment before use.

9. Work permit system as given in 18:5216-1969. Follow this IS for electrical work.
10. Safety tags and safety warning notices.
11. Use of m a chine/ equipment within their limits i.e. no overloading.
12. Placement of oil type transformer outdoor.
13. Auxiliary room, battery room and control room to be separated.
14. Two exits in each electric room.
15. Switch gear of the supply company should be separated from that of the consumer' by a fireproof wall.
16. Precautions against thermal and mechanical stress, moisture, dust and overvoltage. Automatic voltage regulators and overvoltage relays to protect from overvoltages.

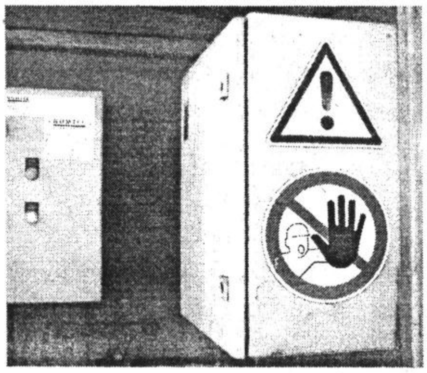

Fig 11.4 : 'Don't touch' Notice on high voltage electric Panel Board

17. Guard on transmission lines to prevent fault due to birds.
18. Verminproof enclosure for indoor switchgear. ?
19. Use of electric shock guard (ELCB) and 3-pin plug and socket to have proper earth connection.
20. Use of reactors or current limiting impendences or underground neutrals to reduce fault levels.
21. Use protective relays, circuit breakers and rated fuses to control the current and to isolate the faulty equipment speedily and automatically. Check before closing an OCB for high voltage lines.
22. Use of grounding mat of low ohmic value and all non current-carrying parts to be connected to the grounding grid by duplicate earth and segregated non current carrying metallic parts to be electrically bonded.
23. Record of ground resistance values and the physical condition of the grounding mat.
24. Temperature sensitive alarm and protective relays to make alert and disconnect equipment before overheating.
25. Interlocks to put into and out of service equipment correctly.
26. Testing for high voltage, timing, polarity and insulation resistance.
27. Cleaning and application of silicon grease to insulators to reduce pollution deposits.
28. Safe cable trenches and preferably armoured cables.
29. Transformers with oil safely, D.O. fuse, L.T. fuse, MCB, MCCB and automatic fire protection system.
30. Generators and motors with fire proof doors automatically actuated by fire detectors.
31. Ready CO, type and other fire extinguishers.
32. Double communication systems with critical areas.
33. Clear approach available for fire fighting squad.
34. Flame and shock detectors and central fire annunciation system for fire safety.
35. Diesel pump set for required fire water pressure.
36. Good housekeeping including well maintenance of all electrical installations.
37. Adequate working space and means of access around each apparatus.
38. First-aid boxes and respiratory equipment ready. Training for artificial respiration to save life from shock.
39. Prevent higher humidity and temperature near electric installations. Work with full protection in raining.
40. Use of flameproof/explosion proof equipment in flammable/explosive areas.
41. Earthing and bonding of solvent carrying pipelines and equipment.

5.2 Main Safety Measures :

They include -

1. **Isolation :** Live electric wires/parts should be kept out of reach from the normal working. Safety distances mentioned in Part 4.6 are one way of isolation. Cable trench is meant for isolation. Instead of providing transformers on ground level (this condition in industrial estates and on roads anywhere is most dangerous) they must be placed at a safe height with wire fencing. Provide segregation or a locked room if isolation is not possible. Circuit breakers and power isolation switches must be provided at appropriate places.

2. **Insulation :** Where isolation is not possible and electrical equipment or wiring are on the working level, cable, conductors and leads should be insulated with standard material. Double insulation means providing second layer of protective insulation. Then earthing is not required. Portable equipment like electric shavers, hair dryers, hand tools are of this type. Personal insulation means to protect the self by dry clothing, rubber shoes, rubber mat etc.

3. **Current limitation :** Only limited current should pass through the equipment. Excessive current should be stopped. This is done by providing fuses, circuit breaker or isolators. The size of the fuse is important. It should blow out when any short-circuit or earth current passes. A 5 amp fuse does not mean that it will blow at 5 amp. It only means that it is capable of carrying current of 5 amp continuously without getting hot. Generally fuses upto 10 amp rating are designed to blow at three times its rated value and those above 10 amp, at twice the rated value. Therefore, it is unsafe practice to tie a thick or more wires in a fuse. Then it may allow higher current, even more than the rated capacity of the equipment and damage it Switches may burn and become black. Low fuse value to limit current is the simpler and cheaper safety device.

4. Earthing : Proper earthing is equally important as fuses. If an equipment is properly earthed, the higher earth (fault or short circuit) current will pass through the fuse or circuit breaker to the earth. This will open the circuit to protect the equipment. Earth conductor should be checker frequently for continuity and tightened if founds loose. Maximum permissible earth resistance ft different fuse sizes are as under:

Fuse Amp	Earth resistance in ohm (max)
5	15.3
10	7.6
20	5.7
30	3.8
60	1.9
100	1.1
200	0.59

Thus earth resistance should be regularly checked and maintained as per requirement.

5. **Other Precautions :** These include sufficient working space, means of access, proper lighting, use of PPE, FFE, avoidance of loose, broken or open wiring, contact of metal parts and trained and competent personnel. While working on live conductor or equipment full sleeves are more useful as dry cloth gives some protection against shock. Don't wear or keep any metallic ornament or metallic part on body.

6 OVERLOAD AND OTHER PROTECTIONS

In industrial buildings, appropriate protection at switch-boards and distribution boards for all circuits and sub-circuits against over current and earth faults is necessary. The protective apparatus should be capable of interrupting any short-circuit current that may occur, without danger. The ratings and settings' of fuses and the protective devices shall be coordinated so as to afford selectivity in operation where necessary. Setting of HRC fuses should be proper. Supply of electric lighting and emergency services should be through separate main service and distribution boards from the power circuits.

Majority of electrical accidents can be avoided if (1) Live parts are insulated in effective and durable manner and positioned safely (2) Conductive parts of the equipment or machines should be earthed or double insulated and (3) All components must be so dimensioned as to withstand design stresses

6.1 Power Cutting Devices (Means of Cutting of Power):

These are switches, switch with' fuses, isolating links or circuit breakers. Where rapid operation is required, switch fuses and isolating links are not suitable. Separate switches should be provided to transformers, motors and apparatus at convenient places. For motors, switches should be close to the starters. Locking arrangement on switch or starter prevents accidental starting. If locking is .not possible, fuses should be taken out while working on that line. Earthing of conductors, particularly of high voltage or overhead lines, is necessary. Mechanical devices are clutches and belt striking gears.

Restriction on use of Switch on Neutral Earthed Conductor:

A single pole switch should not be placed in the neutral conductor of a system which is connected to earth (except for special purposes in generating stations).

If this conductor is bare, even double pole switch should not be placed in this conductor except for the purpose of breaking connection with generators and transformers supplying the power. But the connection with earth should not thereby be broken.

Important Safety Requirements in Design and Use of Switches, Switch-Fuses, Circuit-Breakers and Isolating Links.

1. Sufficient capacity for making and breaking contacts.
2. Cover for switch.
3. Handle spindle should be a close fit in die hole in order to prevent injury from arcs inside. Handle should be insulated.
4. "On" and "Off" position in switches and circuit breakers should be clearly marked.
5. Ample space between opposite poles of double and multi-pole air break switches and circuit-breakers.
6. They should make and maintain good contact on being operated without any special skill or manipu lation.
7. Switches and circuit-breakers should be of such construction that they cannot be left in partial contact, that there is speedy breaking of contact, when operated to off position. There should also be other extra means of controlling the arc where necessary.
8. Handle should be of sufficient size consistent with the effort required to operate. It should be insulated and earthed.
9. Isolating links and switches without insulated handles should be operated by safe means such as by insulated poles.

6.2 Types of Protections :

6.2.1 Capacity and Protection of Conductors, points and Connectors :

All apparatus and conductors should be of sufficient size and strength. They should be covered with insulating material and placed or enclosed as to prevent danger, viz. (a) Conductors in conduit (b) Conductors in flexible metallic tubing (c) Conductors in metal trunking (d) Conductors with metal sheeting (e) Insulated cables like V.I.R. and C.S.T. Cables (f) cables in trench.

Overhead trolley wires of cranes should be (1) either protected by screen guards with suitable opening for tapping, or (2) insulated cable self-winding drums should be used.

Screw cap lamp holders in which the screw position of the holder and the lamp cap are conductive, should be fitted with suitable shrouds or skirts or protected in any other suitable way.

Electrical joints and connections should be (proper construction as regards conductivity, insulatiol mechanical strength and protection.

6.2.2 Overload and Short Circuit Protection

introduced as in the case of motors etc., possible excessive temperature rise in equipment anc conductors should be considered. The number of item: collectively protected should be limited to avoic overfusing to withstand .heavy switching currents anc to ensure subdivisions so that inconvenience fron

operation of protective gear is not caused.

Fuses, relays and circuit-breakers should be of sufficient breaking capacity to operate safely at short circuit currents. Arcing or scattering of hot metal of fuses may be prevented by the use of improved fuses of cartridge or other type having special arrangements for extinction of arc at reduced current values.

Safety in Renewal of Fuses or Fusing elements

1. Operation Without Switching Off : Here switchfuses are used. For heavy current circuits, switches should be provided and operated before operating the fuses.

2. Operation After Switching Off : This is the safest and should be the general practice. Requirements are : (a) Interlocking with switch (b) Independent switches to be accessible (c) Combined switch and fuse boxes should have live parts shrouded or protected.

Circuit-breakers where short circuit current exceeds 10000 amperes or 150 MVA should not be direct hand-operated.

Thermal Protection : Thermal fuses and relays, operating on temperature rise are suitable for use with circuit or appliances where the fault current does not exceed the load current "or where small overloads can cause burn out.

Examples are : (1) Choke coils of fluorescent tubes (2) Fractional horsepower motors (3) Radio sets.

Equipment such as motors which require heavy starting currents can be effectively protected by thermal relays.

6.2.3 Earth Fault Protection :

Protective Earthing:

All non-current carrying metal parts of electrical equipment, should be earthed. Such parts are : (1) Metal conduits, bus bar, steel trunking and cable sheets (2) Non-current carrying metal parts of (a) Switchgear, fuse and starters (b) Generators and motors (c) Lighting fittings and (d) Other electrical equipment or appliances.

To earth is to connect to the general mass of earth in such a manner as will ensure at all times an immediate discharge of electrical energy without danger and to allow sufficient current to flow to blow fuses or operate protective devices and thereby

. disconnect faulty apparatus.

Good earthing can be achieved by connecting earth continuity conductor to :

1. Sheath and armour of "supply" cable whenever available.
2. In the case of supply from own transformer to a heavy section copper wire running to the neutral point of the transformers, and 3. Neutral wire where "protective multiple earthing" is allowed and adopted.

In the absence of these, connection should be made to earth electrode or electrodes having low resistance to earth.

Connection between earth lead and earth electrode should be made wherever possible above the ground for facilitating inspection. Joints involving dissimilar metals should be avoided. All joints should be treated with a conducting paint.

In all cases the earth continuity conductors should have sufficient current carrying capacity to take the fault current safely till the fuse or the circuit breaker blows or trips. The total impedance from any point in the system to the earthing point and through it to die general mass of -earth and then to the neutral point of the supply substation transformer and back to the fault point through the line conductor should be as small as possible (4 ohms for 15 A fuse and I ohm for 60 A fuse for voltage 240 V). Wherever conduits and sheaths are used as earth continuity conductors (without separate earth wire) earth continuity should be ensured at joints and junctions by suitable connections.

Earthing of Electrically Driven Machine Tools :

The bed plates of all mad-lines should be earthed with copper conductor of adequate size. Each control gear casing such as starters etc., should be connected to the bed plate. Where the motor is movable on the machine and hence does not make proper contact with the bed plate, flexible copper wire should be provided

Electrical joints and connections should be proper construction as regards conductivity, insulation, mechanical strength and protection.

6.2.2 Overload and Short Circuit Protection :

Danger from excess current due to overload or short-circuit should be prevented by providing (1) Fuses (2) Circuit-breakers or (3) Thermal protection.

Protective apparatus should be set at a low current protection are introduced as in the case of motors etc., possible excessive temperature rise in equipment and conductors should be considered. The number of item: collectively protected should be limited to avoid overfusing to withstand .heavy switching currents anc to ensure subdivisions so that inconvenience from operation of protective gear is not caused.

Fuses, relays and circuit-breakers should be of sufficient breaking capacity to operate safely at short circuit currents. Arcing or scattering of hot metal of fuses may be prevented by the use of improved fuses of cartridge or other type having special arrangements for extinction of arc at reduced current values.

Safety in Renewal of Fuses or Fusing elements

1. Operation Without Switching Off : Here switch-fuses are used. For heavy current circuits, switches should be provided and operated before operating the fuses.

2. Operation After Switching Off : This is the safest and should be the general practice. Requirements are : (a) Interlocking with switch (b) Independent switches to be accessible (c) Combined switch and fuse boxes should have live parts shrouded or protected.

Circuit-breakers where short circuit current exceeds 10000 amperes or 150 MVA should not be direct hand-operated.

Thermal Protection : Thermal fuses and relays, operating on temperature rise are suitable for use with circuit or appliances where the fault current does not exceed the load current "or where small overloads can cause burn out.

Examples are : (1) Choke coils of fluorescent tubes (2) Fractional horsepower motors (3) Radio sets.

Equipment such as motors which require heavy starting currents can be effectively protected by thermal relays.

6.2.3 Earth Fault Protection :

Protective Earthing:

All non-current carrying metal parts of electrical equipment, should be earthed. Such parts are : (1) Metal conduits, bus bar, steel trunking and cable sheets (2) Non-current carrying metal parts of (a) Switchgear, fuse and starters (b) Generators and motors (c) Lighting fittings and (d) Other electrical equipment or appliances.

To earth is to connect to the general mass of earth in such a manner as will ensure at all times an immediate discharge of electrical energy without danger and to allow sufficient current to flow to blow fuses or operate protective devices and thereby disconnect faulty apparatus.

Good earthing can be achieved by connecting earth continuity conductor to :

1. Sheath and armour of "supply" cable whenever available.
2. In the case of supply from own transformer to a heavy section copper wire running to the neutral point of the transformers, and
3. Neutral wire where "protective multiple earthing" is allowed and adopted.

In the absence of these, connection should be made to earth electrode or electrodes having low resistance to earth.

Connection between earth lead and earth electrode should be made wherever possible above the ground for facilitating inspection. Joints involving dissimilar metals should be avoided. All joints should be treated with a conducting paint.

In all cases the earth continuity conductors should have sufficient current carrying capacity to take the fault current safely till the fuse or the circuit breaker blows or trips. The total impedance from any point in the system to the earthing point and through it to die general mass of -earth and then to the neutral point of the supply substation transformer and back to the fault point through the line conductor should be as small as possible (4 ohms for 15 A fuse and I ohm for 60 A fuse for voltage 240 V). Wherever conduits and sheaths are used as earth continuity conductors (without separate earth wire) earth continuity should be ensured at joints and junctions by suitable connections.

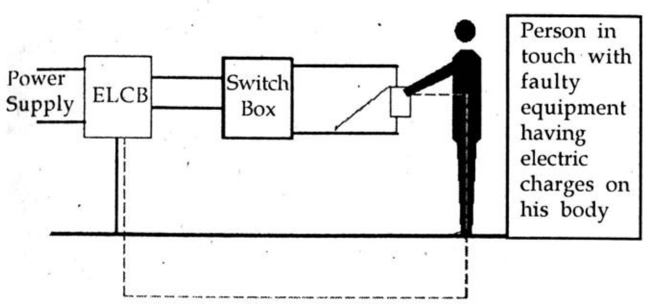
Earthing of Electrically Driven Machine Tools :

The bed plates of all mad-lines should be earthed with copper conductor of adequate size. Each control gear casing such as starters etc., should be connected to the bed plate. Where the motor is movable on the machine and hence does not make proper contact with the bed plate, flexible copper wire should be provided to connect the motor and the bed plate. In bed plates and control gear casing, separate terminals should be provided for earthing. Flexible metal tubes used to protect wiring at motors should not be used as earth conductor, but a separate earth conductor should be run within it.

Portable power tools (hand-held electric drills, grinder, cutter etc.) must also be earthed or double insulated, otherwise fault current gives a severe shock. For details see Part 7.

Earth Leakage Circuit-Breakers (ELCB) :

Where it is not practicable to obtain low impedance or where protection afforded by the over current fuses and circuit breakers along with the earthed, conductors is not adequate, leakage protection can be achieved by: (1) Voltage-operated earth leakage circuit-breakers (2) Differential current circuit-breakers or (3) Combined voltage-operated and differential current circuit-breaker. The current operated ELCB operates even at 0.5 amp current and reduces fire risk. For further safety special 4 pin plug and socket and a 4 core flexible cord arc available.



If an earth leakage circuit breaker (ELCB) is provided, it will operate due to rise in earth voltage or current and open the circuit as fuse opens. This will stop the current towards equipment or machine, it will be de-energised and its contact will become safe..

Relays are utilised to actuate at pre-set threshold voltage or current and to isolate the appliance in which the dangerous condition has developed.

6.2.4 No Load Protection :

Over current condition is generally known as 'overload' condition. It should be protected by equipment which will operate at excess (more than rated) current and stop the supply. Similarly low current or low voltage condition is said to be 'no-load' condition and it also needs to be protected. Simple running of an electric motor without rotating the pump, generator or machine shaft, is known as no-load working. It draws minimum current depending on winding resistance. With the same resistance, if the voltage is reduced, it will reduce the current. In such condition, the use of fuses as a tripping device is generally preferred.

In low voltage system if the circuit is direct current type or heavily loaded, the slow operation of fuses (low current) often results, in arcing or flashover followed by burning of the contacts and this is dangerous for service personnel. Therefore they should be protected by following measures.

1. Employ trained electricians and give them full information regarding possibility of arcing from fuses.

2. Handles of the switch or fuse-box should be insulated. Leather, hand-gloves (up to elbow) should be given to workers.

3. No load protection and protection against accidental contact are also necessary. At no load, no more current is desired. Therefore low current rated fuses are to be selected. .

4. Fuse box cover should have small aperture to introduce the end of a voltage tester to ensure that the contacts are live or not. The box (flashproof) cover should be such that when it is opened, it will stop the current.

6.2.5 Earth, Insulation and Continuity Tests:

When electric current passes through its expected resistance (load) path, its energy is utilised in heating, rotating or doing the required function. But when due to insulation failure, breaking, opening or loosening of conductor or directly touching to any metal part, tool or a human body, the current passes through the line of least resistance i.e. instead of passing through its regular machine or equipment circuit, it jumps (diverts) to the metal part or human body and tries to flow through the lowest resistance to the lowest potential. Now the earth has an extremely low electrical resistance and practically zero voltage, the leaking current (i.e. earth or fault current) tends to flow through the metal part or the human body to the earth if they are touching the earth. If the human body is separated or insulated from the earth by insulating material like rubber gloves, rubber shoes, rubber mat, wood etc., the current will not flow through the body and the shock can be avoided. Similarly metallic exposed part if not earthed, will remain live and if some one touches it or metal contact between the exposed part and the earth is available, the current will flow to the earth.

Therefore from safety point of view, if metal part of the equipment, machine, vessel, structure, pipe etc. are, in advance, properly earned i.e., connected by an earthing conductor to the earth pit of low resistance, accidental earth fault current will flow through it. Supply voltage being die same and the resistance being reduced, the current will increase due to E=IR. This heavy current when passes through the fuse, it melts and the circuit becomes open.

Besides earth tests, it is also necessary to carry out insulation and continuity tests of installations and apparatus at periodical intervals. This is necessary to ensure that insulation values are within safe limits and that there is continuity of the circuit without excessive leaks. These can be carried out easily with special type of instruments.

Thus earth, insulation and continuity are considered for-safety purposes and they should -be tested for protection. If insulation breaks, live conductor or a metal part is exposed and it is danger. If continuity of a conductor is broken from inside, supply side is energised but not known and may cause hazard. While the other side is broken, the equipment does not work due to discontinuity. If the earth conductor is discontinued, it is like 'no earthing' and poses great hazard. Therefore continuity of earthing conductor is most important.

In earthing system, neutral conductor of the distribution power system is connected to earth at many places by parallel conductors. This system is known as Multiple Earthed Neutral (MEN) or Protective Multiple Earthing (PME) system. This system has the widespread use in the world.

Earth resistance should be kept low to keep the earth temperature low. Therefore earth resistance should be periodically checked and maintained.

Insulation and continuity tests are necessary to ensure that insulation values are within safe limits and the circuit is continuous (unbroken) and without excessive leaks. Instruments are available for such tests.

6.2.6 Earthing Standards :

IS:3043, Code of Practice for Earthing and SP 30 National Elective Code must be referred for details of earthing.

Earthing means a low impedance return path of the fault current. Actually the earth, now, rarely serves as a part of the return circuit but is being used mainly for fixing the voltage of system neutrals. The earth connection improves service continuity and avoids damage to equipment and danger to human lives.

Earthing of current carrying conductor is known as system earthing, while that of non-current carrying conductor or metal work is known as equipment earthing. The former is essential to the security of the system and the latter to the safety of persons, property and animals.

Following is the synopsis of earthing standards mentioned in Section 12, Part I of our National Electric Code:

1. The purpose of system earthing is to preserve the security of the system. There should be two separate and distinct connections with earth through an earth electrode.

2. The earth system resistance should be such that the fault should operate the protective gear (fuses or circuit breaker) to isolate the faulty portion.

3. The purpose of equipment earthing is to protect the equipment from danger to life or risk of fire due to leakage of current through the metal work and through the person in contact. The leaking current operates the protective gear due to earthing.

4. In case of high and extra high voltages, the neutral points shall be earthed by two or more separate electrodes.

5. Earth electrodes shall be provided at generating stations, substations and consumer premises as per requirements.

6. As far as possible all earth terminals should be visible. The connections should be adequate and tight.

7. Normally the earth system resistance should be less than 1 ohm, unless otherwise specified. Testing of earth electrode should be possible.

8. The current carrying capacity of the system should not be increased so as to increase the earth fault current or its duration to make the earthing in-capable of bearing new value.

9. All materials, fittings etc. used in earthing should conform to Indian Standard.

10. Design of earth electrode dimensions should consider electrical resistivity of the soil. The earth conductivity depends or moisture content of the soil, salts in the water, chemical composition, grain size and distribution etc. These factors vary locally and some seasonally. Local values should be verified by actual measurement.

11. The step potential and touch potential should be measured and kept within safe limits.

12. The size of earth-continuity conductors should be correlated with the size of the current carrying conductors. The sizes of the earth-continuity conductors should be more than half of the largest current carrying conductors. The range of earth-continuity conductors should be as under:

Material	**Min**	**Size**	**Max**	**Size**
Copper	1.5	mm^2	70	mm^2
Aluminium	2.5	mm^2	120	mm^2

13. Earthing of electrically driven- machine tools should be as under :

Material	**Strip or Conductor size (min)**
Copper	$6.5mm^2$
Aluminium	$10\ mm^2$
Steel or GI	$16\ mm^2$

The bed plate should be securely fastened by a bolt.

14. Earthing of portable appliance and tools should be continuous i.e. no twisted or taped joint should be used in earth wires. A single pole switch should not be connected in earth conductor. Fixed wiring at appliance inlet terminals must be done correctly and as per IS Appliance having double or reinforcement insulation need not be earthed.

15. Following rules of the Indian Electricity Rule; 1956 are relevant on earthing standards :

Rule Subject

32	Identification of earth conductors.
33	Earthed terminal on consumer’s premises.
51	Provisions for power installations.
61	Connections with earth.
61 A	Earth leakage protective device.
62	System at medium voltage.
67	Connection with earth.
69	Pole type substations.
88 (2)	Guarding.
90	Earthing.

6.2.7 Protection against Surges and Voltage Fluctuation:

When equipment is switched on, momentarily initial excessive currents are known as current surges or transient current.

Surges may be more in starting cold circuits than the hot circuit i.e. restarting of the previously live circuit which was closed for a short while. For example, when large banks of filament lamps are switched on, current surge arises, because they have, much lower resistance when cold than when hot. If a live lamp circuit is made off and soon reenergised, it will face fewer surges. Therefore fuse or circuit breaker rating should consider this surge phenomenon or its effect given as Pt where I = current, t = time and [Ft] known as pre-arcing of a fuse or let through of a fuse or circuit breaker or withstand of a component e.g. diode.

Current surges are also produced when large banks of condensers are switched on. For example if the condensers have retained a charge of the reverse polarity and its circuit is energised at the moment of maximum voltage, a very large charging current will flow. When condensers are switched for power factor correction or tuning on high frequency furnace installations, high surge current flows. To prevent damage, large HRC fuses are sometimes placed between sections.

Switching large power transformers or starting up motors driving high inertia loads, also cause large current surges if closure occurs near maximum voltage. H is therefore important to ensure that the motor and starter are both suited to the duty. Failure to do this may cause the motor to burn out or the starter to explode.

During surge current, [Pt] denotes a measure of the damage or the specific energy of the operation and can be defined as the energy dissipated as heat during a specified operation per ohm of resistance. Therefore for protection against surges, values of the protecting device should withstand [Pt] value. This can be dealt with in the light of experience by increasing settings and fuse sizes. It does, however, militate or resist against close protection.

Voltage fluctuation from the electricity supply lines has become a common phenomenon at many places. Supply voltage goes down resulting in reducing speeds of fans, motors, machines etc. and reducing lamp lighting. Again it comes and stabilises the condition. Such voltage fluctuation, if on higher side, may blow fuses or protection and if on lower side, reduces the productivity or effect of equipment.

Automatic voltage regulator or voltage stabiliser, either built-in with the equipment (mostly with household appliances like freeze, TV etc.) or external are readily available.

Voltage fluctuation on either side is harmful. It 'accelerates or decelerates speed of machine or production. It damages furnaces by over or under heating. It increases or decreases lighting, ventilation, voice etc. and many power dependent parameters. Change in temperature affects reaction rate in chemical processes. It affects radio, TV, computer, hand tools and many home appliances. Over voltage causes over current which may increase the intensity of shock and flashover. Electric motors, fuses, starters, switches, wiring, insulation may burn due to over voltage and overheating. Therefore over voltage or under voltage must be prevented by appropriate automatic voltage regulators or by power cutting devices. See part 6 for overload and other protections.

Travelling voltage surges may become weaker by surge absorbers which are designed to dissipate energy by eddy currents and/or hysteresis loss or by a sufficient length of cable. Over-voltages can be relieved by spark gaps or by various devices which are insulators at normal voltages but breakdown at a prescribed over-voltage. They may or may not be 'self healing'.

Voltage spikes caused by current chopping may be avoided by a proper choice of cartridge fuses and others suppressed by shunt connected silicon or other semi-conductors for power circuits and zener diodes for light current circuits.

The possibility of flash over in high voltage trifurcating boxes on transformer, switchgear or motors is prevented by better insulation, filling techniques and/or phase separation.

Disconnected overhead line in the proximity of other overhead lines, should also be kept earthed, otherwise it may cause shock due to voltage induced in it.

6.2.8 Hazards of Borrowed Neutrals :

Now-a-days mostly the 4-wire, multi-grounded, common-neutral distribution system is used exclusively because of their economic and operating advantages. In a star system the neutral point is solidly grounded. Sometimes a small amount of impedence is inserted between the transformer neutral and ground in order to limit line-to-ground short-circuit currents on the primary system to a predetermined value.

The neutral circuit must be a continuous metallic path along the primary routes of the feeder and to every user location. Where primary and secondary (single phase) systems are both present, the same conductor is used as the common neutral for both systems.

The neutral is grounded at each distribution transformer, at frequent intervals where no transformers are connected and to metallic water pipes or driven grounds at each user's service entrance.

The neutral carries a portion of the unbalanced or residual load currents for both the primary and secondary systems. The remainder of this current flows in the earth. Ground electrode should have a resistance less than 25 ohms.

Where there is no secondary neutral and no distribution transformers, the primary neutral should be grounded at intervals of 500 to 1000 ft. By a direct buried, concentric neutral cable, the excellent grounding is obtained.

Hazard arises when there is a discontinuity in the neutral path. Therefore no disconnecting devices should be installed in the common neutral. In no case, the earth or buried metallic piping system should be used as the only path for the return of normal load current.

In borrowing of neutral by tapping or otherwise, hazards arise if the size of the neutral conductor is changed in new line or any discontinuity is left somewhere or if that line becomes the return path of normal load current.

In a 3-phase balanced primary circuit, the neutral conductor can be of a smaller size than the phase conductor, but in a single-phase primary circuit (phase and neutral), the neutral conductor should be large enough to carry almost as much current as the phase conductor. Mostly the same conductor size should be used for both, the phase and the neutral to avoid the hazard.

6.2.9. Lockout and Tag-out :

Lockout and Tag out are generally industrial practices indicating 'warning' that the equipment or machine so locked or tagged out shall not be used till that lock or notice is removed.

Lockout means making the equipment / machine inoperative or power - isolated so that it cannot be started or used. Locked label or notice of 'Lockout' indicates that this equipment or machine is faulty, under repair or-maintenance and is locked for the purpose of not using it till this lock or notice exists.

Tag-out means to tie a tag on the equipment or machine to indicate that it is under repair or maintenance and not to be touched or used. Tag out is most essential when lockout is not possible. It can be used in addition to lockout for further precaution.

Lockout and Tag out procedure is also required to prevent accident from unexpected starting or operation of any switch, starter, motor,, equipment etc. .When some repair or maintenance work is to be started on electric line or some vessel, pipe line etc, source of supply of power, energy, flow etc needs to be isolated and for this purpose, such switch, lever, valve, control knob etc should be kept in locked off position by positive locking and tagging indicating instruction not to open the lock or operate that switch, valve etc.

When more than one department wants lockout of the same switch, valve, equipment etc, each of them should apply their own lock and tagging. In such multiple locking, each key should be different and no master keying should be available. In case of difficulty, lock may be broken down but no duplicate key should be available.

Procedure of lock out should be established. It should include

1. Before locking or tagging, inform the concerned operators and users that line, switch, valve or equipment will be isolated or de-energized and give them time to complete or stop their work.
2. Plan the shut down and make the system off.
3. Insert lock and attach tagging.
4. Test that the isolation is positive and as, per expectation.
5. When repair / maintenance work is over, open the locking and tagging.
6. Again inform the concerned people that locking / tagging is removed and they can work as usual.

6.3 Lightning Arrester :

Purpose of lightning arrester is to attract lightning from the sky and to bypass it into the ground and not allowing it to pass through any combustible material.

A pole type long rod of good conductor is attached on the tallest structure at site. Because of its good conductivity (low electrical resistance) electrical current of the lightning is directly passed into the earth it is necessary to check its continuity and resistance of the lightning arrester at regular interval.

It is not desirable to attach lightning arrester directly on the metal tank of flammable liquid or gas because in case of unknown discontinuity, lightning may pass through the metal surface and the whole tank may trap in to the fire.

IS : 2309 and 4850 are useful in this regard.

7 PORTABLE ELECTRICAL APPARATUS

Portable electrical apparatus have caused many accidents. Metal-cased apparatus is often held firmly in the hand by person whose foot usually make good contact with floor or metal work. The flexible cables are subject to much bending, rubbing and hard use. The appliances or tools are subjected to vibration and rough treatment in use. In those circumstances special precautions are required in installation, maintenance and use of portable apparatus.

See Part 4 of Chapter-17 for hazards and safe use of portable power tools.

Cable and Connections : Portable apparatus to the system should have efficient permanent joints, connections or connectors.

The cable should be reinforced at the place where it enters the plug with stout rubber tubing or metallic spiral. The cable grip should be such that outer covering or sheathing is securely held and no strain is placed on conductors. Hand shield, disc or other types of guard between grip or handle part and the portion containing cable and contact pins should be provided. Three pin protective plug and socket should be used.

Earthing Insulation : All non-current carrying metal parts of portable apparatus and pendant lamps should be earthed unless suitably covered with insulating material. The flexible metal covering of conductors should also be earthed; but it should not be the means of earthing the portable apparatus, as the resistance of such metallic covers are high.

Lamp holders of portable lamps should not be in metallic contact with the guard or other metal work. They should be insulated and the other metal parts earthed. For use near live conductors, hand lamps having completely insulated exterior and guards should be used.

For use in dangerous situations such as inside of boilers or tanks or damp and exposed positions, low voltage lamps or tools should be used. A pressure of 24 volts with 12 volts to earth is recommended.

Earthing resistance should be checked frequently and wherever it is difficult to obtain a low resistance, other methods of earth fault protection described earlier (e.g. ELCB) should be used in addition. Systems having monitoring current which will trip the supply if there is break in the earth connection or if the resistance is high, provide adequate protection.

See Part 6.2.6 and its para-14 & 15 for earthing of portable appliances.

Portable Transformers : The main hazard with metal cased portable transformers is that if the earth wire becomes detached in the mains-plug and touches live wire, the secondary neutral and the metal case will praised to phase voltage of the mains. The apparatus will thereby be charged to phase potential. The remedies are : (1) Constant inspection (2) Provision of "stations" with two separate earthed sockets, one for mains supply from the transformer (3) Transformer with insulated casing.

Portable apparatus operating at low voltage (e.g. 110 V) are more safe than those operating at higher voltage.

8 ELECTRIC WORK IN HAZARDOUS ATMOSPHERE

8.1 Classification of Hazardous Areas :

In chemical, petrochemical, refinery and fertiliser factories and also in coal mines, combustible/explosive dust, vapour and gases may evolve during normal or abnormal operating conditions.

These gases coming into contact with air make an explosive air-gas mixture which is hazardous to the installation of electrical apparatus as well as to the workers.

IS'.5572 divides the hazardous area (containing flammable gas or vapour capable to be ignited) into following three zones for the purpose of appropriate electrical installation :

Zone 0 Areas : Here hazardous atmosphere exists continuously viz., the vapour space of closed process vessels, storage tanks or closed containers. Any spark will certainly lead to fire or explosion. Therefore, any electrical apparatus in this zone must afford an absolute protection. It is recommended that the use of electrical apparatus should be avoided in this zone, but when it is not practicable, IS:5571 (Guide for selection of electrical equipment for hazardous areas) should be followed.

Zone 1 Areas : Here hazardous atmosphere is likely to exist at any time. Therefore the fullest practicable measures should be applied to prevent a hazardous electrical condition at any time and in any circumstances. Recommended types of electrical apparatus and wiring for use in Zone I areas are given in IS:5571.

Zone 2 Areas : Here hazardous atmosphere is likely to occur only under abnormal operating conditions. This classification is applicable only where a fire or explosion hazard is unlikely and may be caused only by the simultaneous and improbable occurrence of an arc or spark resulting from an electrical failure and a hazardous atmosphere arising through failure of the conditions of control. It presupposes that any hazardous atmosphere resulting from an abnormal occurrence is rapidly dispersed so that possible contact with the electrical apparatus is of minimum duration. Any situation which allows a hazardous atmosphere to collect, such as pit or trench, although, it may be in the open air, shall in itself be classified as Zone I area, even though the surrounding area is classified as Zone 2. Where doubts exist in any specific case, a Zone I classification should be adopted.

8.2. Flameproof Electrical Equipment :

The types of protection generally applicable to electric motors for use in hazardous areas are:

1. Flameproof or Explosion proof, Type-d
2. Increased Safety, Type-e
3. Intrinsic Safety, Type-i
4. Non-Sparking, Type-n
5. Pressurised, Type-

IS:5571 guides us for selection of electrical equipment (motors, transformers and capacitors, lighting fittings, switchgear and control-gear) for hazardous areas. IS:2148 gives specification for flameproof enclosures of electrical apparatus and IS:4691 for degrees of protection provided by enclosures for rotating electrical machinery. IS 4012 for dustproof electrical lighting fitting, 2206 (Part I to 4) for flameproof electric lighting fittings, 8945 for electrical measuring instruments -for explosive gas atmosphere, 7118 for direction of movement for control devices operating electrical apparatus and 7689 for control of undesirable static electricity are also relevant.

In Zone-1 area flameproof or pressurised type motors whereas in Zone-2, increased safety type motors are suitable. Table 11.9 gives summary :

Table : 11.9 Types of motor protection in hazardous areas:

Type of Protection of Motor	Symbol	Hazardous Zone	Advantages	Disadvantages	IS
Flame-proof	d	1,2	Robust, permits maintenance of internal equipment	Expensive in larger sizes. Difficult to weather proof. Careful maintenance	2148 3682
Increased Safety	E	2	Cheaper, Suitable for all gases Long Life.	Requires careful installation	6381
Non Sparking	N	2	Cheap	Some designs difficult to maintain	8289
Pressurised	P	1,2	Safe, suitable for all gases. Can be modified and maintained	Auxiliary equipment needed to provide dry air on inert gas	7389

For flameproof enclosures, gases and vapours are classified according to their Maximum Experimental Safe Group (MESG). The groups of apparatus are Group I for mining application (methane) and Group II for application in other industries. Group II is subdivided as IIA, UB and IIC. Similarly, gases and vapours are also classified in the same four groups according to the ratios of their Minimum Ignition Currents (MIC) with that of laboratory methane. Table-3 in IS:2148 suggests these four groups for particular gas or vapour, for example, Group I for methane, IIA for ammonia, benzene, acetone, methanoi etc., IIB for ethylene, ethylene oxide etc., and IIC for hydrogen.

Testing of electrical equipment for use in explosive atmosphere is most essential.

Available flameproof equipment include motor, transformer, switch socket, switchgear, limit switches, push buttons, rotary cam operated switches (isolators), switch fuse unit with HRC fuse links, electric bell, fluorescent tube light fixture, wall glass lighting fitting, flood light, control gear box, bulkhead fittings, hand lamp, vessel lamp, safety torch, indicating lamp, ammeter, measuring instrument enclosure, moulded case circuit breaker, distribution board, control station, remote control panels, junction boxes, meter boxes, cable glands and accessories.

ISI mark must be preferred. Rules for installation and maintenance of transformer substation, main switch boards, distribution boards, conduit wiring system, cable wiring, lighting layout, earthing and lighting protection and inspection and testing should be strictly followed for their safe working in flammable/explosive environment. This is statutory requirement also as stated earlier.

8.3 Safety Measures with Low & High Risks Areas :

In low risk area, following Safety measures are necessary

1. Segregation of equipment that may generate heat or spark. For example, fuses, switchboard, transformers, motor, resistance, heater etc. should the segregated. For Rules of segregation, see TAC booklet published by Bombay Regional Tarrif Advisiory Committee.
2. Guarding, insulation and protection of conductors.
3. Earthing of all metal work.
4. Less operation of switches and starters to avoid spark.
5. Covering heaters and resistance to prevent contact with hot surfaces.
6. Interlock switch to ensure making and breaking of connectors with switch in off position.

In high risk area, following safety measures are necessary.

l. Electrical equipment should be flameproof and of the approved type.
2. Pressurised electrical equipment.
3. Intrinsically safe electrical equipment.
4. Segregation of the electrical equipment to the extent possible.
5. Overload, short circuit and leakage protection with close setting up of fuses or overload protective devices.

Besides fire fighting equipment, following fire safety requirements are also recommended :

1.	Area up to 750 m^2	-	Automatic fire alarm system
2.	Area above 750 m^2	-	As above or automatic sprinkler

Refer Part 3.3. for TAC regulations

9 STATIC ELECTRICITY

9.1 Electrostatic Charges & is charges:

Importance of static electricity is increasing with the increasing use of insulating plastic, rubber, chemicals, petrochemicals, films and flammable gases, vapours and dusts.

The generation of static electricity is a surface phenomenon associated with the contact and separation of dissimilar surfaces. Friction is not necessary to generate electrostatic charge, however it increases the release of electrons and production of ionised particles. Conditions necessary for generation of static electricity are :

1. A means of electrostatic charge generation.
2. A means of accumulating the generated (separate) charges and maintaining a potential difference.
3. There must be discharge of the accumulated charge to give sensation or effect of the static electricity. If the discharge i.e. separation is o adequate energy, it will give a spark (which can ignite a flammable mixture).

Thus, static charge is first generated, then accumulated and lastly discharged. Out of these three stages, only last one is visible.

Static charge may occur due to :

1. Contact charging by two dissimilar materials in contact. Plastic films passing over metal rollers (which should be earthed), powders flowing through duct or people walking over carpets may become highly charged.

2. Liquid flow through pipes generates charge due to adsorption of impurity ions. This may readily occur when filters are used with petroleum products.

3. Spray Electrification. Fragmentation of a liquid surface produces charged droplets. Splash-filling of a tank may form a charged mist. In a tanker, incendive sparks may come from charged clouds generated by water sprays for cleaning. Steam-leak also produces charge on isolated metal work viz. nearby pipeline. CO_2 discharge from a fire-extinguisher, may also generate charge.

4. Corona charging. Xerographic copying and electrostatic paint or powder spraying creates charge by air ions.

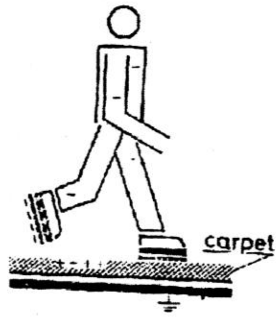
5. Induction charging. Nearby charge raises the potential of an isolated conductor. This may concentrate electric fields and initiate sparking. The electrical energy of a static charge is given by-

$$E = 10^{-3} \frac{CV^2}{2}$$

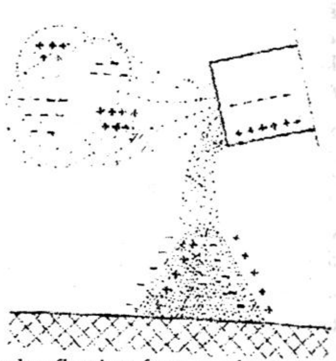
Where E = energy, microjoules, C = capacity of object, picofarads and V = potential, kilowatts. Mixtures of flammable vapours in air require 0.1 to 1 microjoule, flammable dust clouds require 5 microjoules upward and sensitive explosives less than 0.1 microjoule energy to cause ignition.

Charge accumulation must be avoided by detection by field meters (Static volt meters or a capacitance bridge) and various methods of electrostatic charge elimination (hazard control), as stated below. .

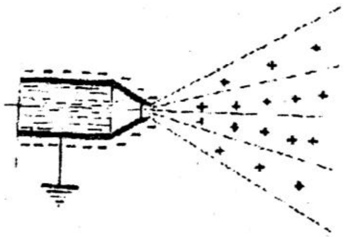
See figure 11.5 for examples of generation of static electricity (charges).



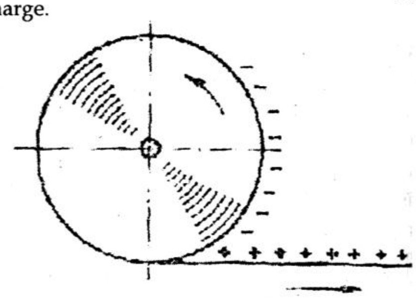
Insulating soles generate charge while walking on carpet.



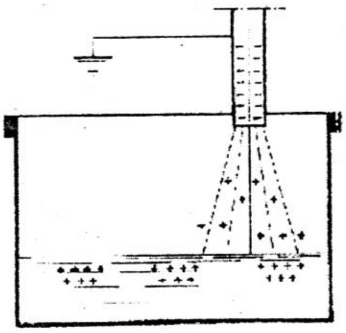
Powder flowing from a plastic bag generates charge.



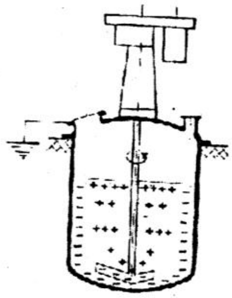
Lequid through matel nozzle generates charge.



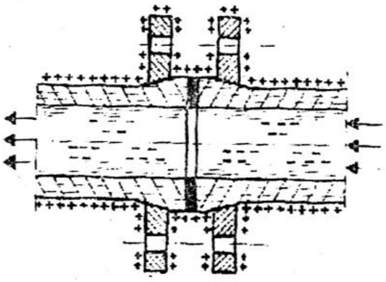
Unwounding plastic or paper film and the roll are charged.



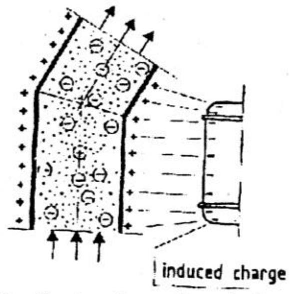
Non conducting solvent flowing through matel pipe generates charge.



Stirring of non conducting liquid in a vessel generates charge.



Non conductive liquid or powder flowing through glass or plastic pipe generates charge.



Powder flowing through a plastic pipe generates charge.

Fig. 11.5 Examples of generation of static electricity (charges).

9.2 Operations and Machines Generating Static Charge

Some examples are as under -

(A) Operations generating static charge

1. Walking on dry floors.

2. Touching and rubbing hand on, plastic hand rails.
3. Flow through long pipe lines of small diameter. Increase in diameter reduces static charge as friction reduces of the same flow.
4. Flow through filters, valves etc.
5. Stirring of liquid at bottom.
6. Splash filling of liquids or high velocity flow. Flow of liquid into tank.
7. Two phase (liquid & solid, liquid & gas or air, gas and solid) flows.
8. Loose floating objects.
9. Flow of air, steam (wet) or gas through opening of hose or pipe.
10. Directing air flow on or near electronic equipment e.g. compressed air cleaning of dust.
11. Putting or moving synthetic material on or near electronic equipment.
12. Putting on and off with jerk synthetic shirt from the human body.
13. Combing of hair
14. Process of mixing or agitation.
15. Rapid flow of powder, palettes, tablets etc. through chutes or pipe.

(B) Machines generating static charge -

1. Rollers or roller contact of dissimilar surfaces or moving belt or conveyor on it e.g. rubber mill, paper mill, calendar machine, dryer rolls etc.
2. Running of non conductive flat belts on pulleys or rolls.
3. Pulverizing machine where pulverized material passes on surfaces.
4. Long conveyor belts moving on support rollers.
5. Feed hoppers, silos and pneumatic conveyor where material slides on surfaces.

9.3 Hazards and Controls :

Static electricity is frequently generated but mostly it is not hazardous because it is too weak or leaks off as fast as it is generated. For its fast leaking or bypassing, good conductor (antistatic device) is required to connect the charged surfaces with the earth.

9.3.1 Hazards of Static Electricity :

As rubber is bad conductor (good insulator) of electricity, it accumulates static electricity to a high degree. Fires in rubber industry are mostly due to discharge of such heavy static charges.

If equipment is not grounded, static charge will continue to accumulate on it till it will discharge as a spark. Therefore grounding by a steel plate, copper wire or bronze brush is necessary.

Lightening from the sky is nothing but a discharge to the earth of enormous static charges generated and accumulated between the layers of air and clouds in the atmosphere.

Some specific hazards are as under

1. Shock if spark is not generated and the charged surface (not grounded) is touched by human body.
2. Fire or explosion if spark is generated due to discharge of static charge into flammable atmosphere.
3. Readings are distorted or changed in sensitive instruments.
4. Dust deposition on charged surfaces.
5. Clogging or obstruction to free flow of powders in chutes, silos or hoppers.

9.3.2 Control of Static Electricity :

Sequence to combat static electricity includes following steps

1. Prevent charge generation.
2. If this is not possible, prevent its accumulation.
3. If this is also not possible, prevent discharge from being hazardous, and
4. Prevent formation of flammable atmosphere near possibility of static electricity.

Mostly step-l is not possible but step-2 can be implemented effectively by ensuring earthing and bonding. For step-3, diameter of pipe/hole is increased, flow rate is decreased etc.

When two unlike materials separate quickly, static charge is generated at the point of separation. Ground wire should be attached where static charge is likely to occur. For proper ground connection, spring type or screw type clamp is used. Ground clamps are made of materials like stainless steel or beryllium copper alloy because they are good conductors of electricity and also non-sparking. Clamps should have sharp points and enough pressure to hold it firmly.

Coating of paint, rust, corrosion, grease, oil, resin etc should be removed at a point where ground connection is to be made. Thus grounding surfaces should be made clean if they are not.

Loose connection, broken clamp, broken wires and unclean metal surfaces should be checked before starting the work. Ground wire must be attached last after making sure that all connections are made properly.

It is important to note that it is more advisable and simpler to avoid having a flammable atmosphere than to try 'for charge avoidance. For this purpose inert gas filling is first required. Some specific control measures are as under:

1. Earthing (grounding) and bonding of equipment, pipe joints, flanges and parts.
2. Increasing the conductance of floors, footwear, wheels and tyres for personnel and moving equipment.
3. Increasing the conductivity of non-conductors by conductive additives, surface layers, films and humidification of the atmosphere.
4. Increasing the conductivity of the atmosphere by ionisation.
5. Using antistatic and conductive materials and static eliminators.
6. Earthing of moving machinery.
7. Use of antistatic belts or antistatic dressing to non-conductive belts at regular intervals.
8. All tanks, vessels, pipelines containing solvents or flammable liquids or gases should be separately earthed. Bonding of pipe lines at flange joints necessary unless metallic contact (continuity) is in between the flanges. Thus bonding is not required for wholly metallic connections having resistance to earth less than 10 ohm. However, bonding is necessary if non metallic (e.g. plastic, rubber, asbestos) components are there in between the joint.
9. Tank wagons and road tankers should be earthed while loading or unloading with flammable liquid or gas. Rail-track should be earthed and jumpers to be provided to connect rail to rail.
10. While pumping flammable liquids in tanks, the inlet pipe should extend and discharge at the bottom of the tank. A long feed (inlet) pipe or inner limpet for this purpose is desirable. At this time it is advisable to maintain an inert gas blanketing. Flow velocity should be restricted.
11. The pipe and nozzle of steam or water should be bonded while tank cleaning or steaming.
12. Liquid spillage and dust deposits should be removed as early as possible.
13. Good ventilation and good housekeeping are necessary to prevent flammable concentration.
14. Non-conducting plastic containers should be avoided to fill flammable liquids with flash points below 30°C.
15. Antistatic additives should be used to reduce the high resistance of liquids.
16. Keep all synthetic material at least 6 inches away from charged surfaces or electronic equipment.

17. While repairing or handling PCB or electronic equipment, use antistatic foam, antistatic grounded wrist strap and antistatic floor mat.
18. Reduce pump or flow speed while beginning tank filling, .transferring light material on the surface of heavy material of low conductivity, using water or air for cleaning purpose, while transferring a product of two phases such as immiscible liquids etc.

The most relevant IS 7689 on control of undesirable static electricity should be referred for 44 topics given therein. They include definitions, electrostatic charge, their physiological effects, discharges, electrostatics in liquids, powders, solids and gases, effect on personnel, earthing and bonding, use of tanks - metallic & non-metallic, road/rail tanker, small containers, transfer of liquids, pipelines, release of gases, spraying of paints and powders, handling of electro-explosive devices, earthing of personnel and hazards from clothing.

For earthing and bonding maximum earth resistance recommended is 10 ohm. Antistatic or conductive type materials can be used to avoid the retention of static electricity. Earth resistance for static charge dissipation should be regularly checked.

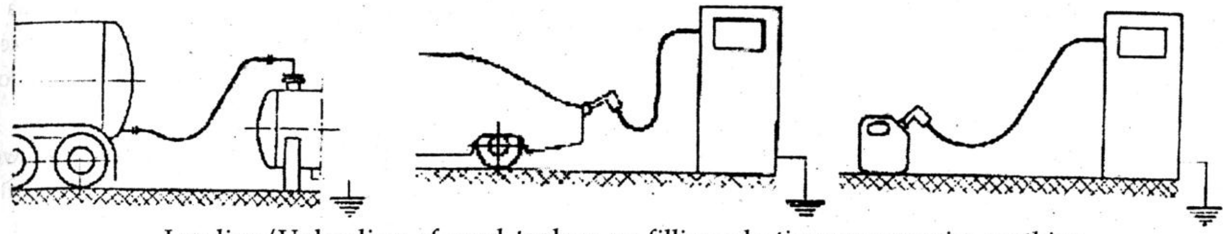
See fig 11.6 for control measures for static electricity.

10 ENERGY CONSERVATION AND SAFETY

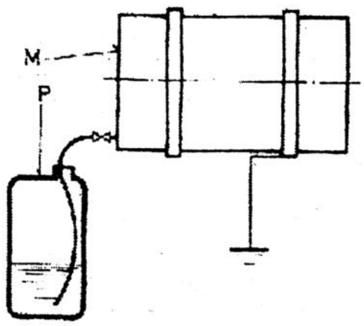
Energy conservation, particularly of electricity and heat, is itself a wide subject and has wide applicability throughout the world. It does not only improve efficiency and economy, but also improves safety and productivity. Thus its benefits are manifold.

See Part 3.1 of Chapter 2 for definition of accident, where it is also defined - in terms of energy loss. Physiological energy loss or energy loss from material, process or unwanted transfer of energy beyond the threshold limit is also called accident. Therefore from safety point of view energy loss should be prevented or minimised.

Energy and safety has direct relationship. High energy may cause more damage in case of accident.

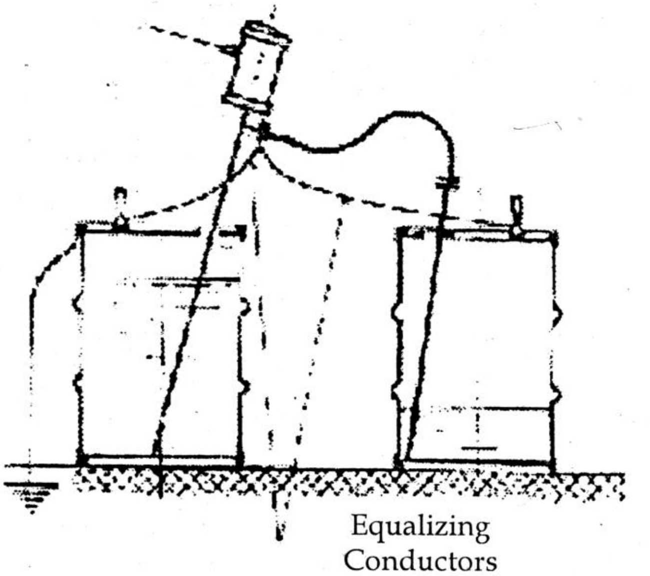


Loading/Unloading of road tankers or filling plastic canes require earthing.

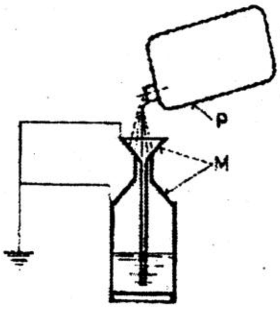


P : insulating plastic material M : Metal

Matel barrel requires earthing.

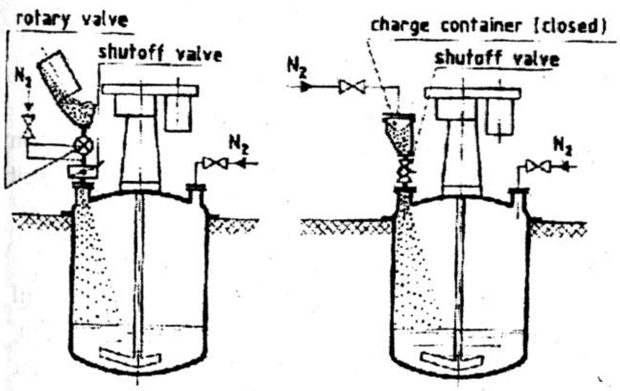


Drum pump and drums require earthing.

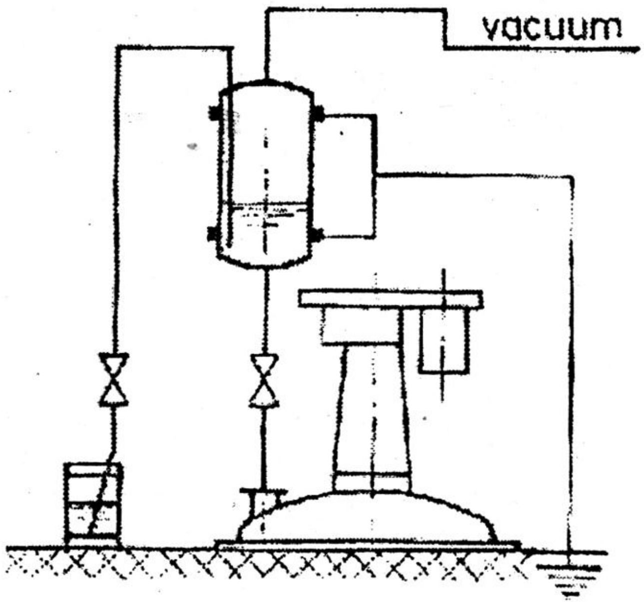


P : insulating plastic material M : Metal

Conductive containers, funnels and nozzles should be earthed and bonded.



Closed charging of solids into an inerted vassel requires earthing (two possible alternatives)



Filling pipe should be extended up to the bottom of the vessel. Measuring vessel and reactor both should be earthed.

Bulk storage of chemicals, operating at high pressure, temperature, flow, speed etc., high frequency radiation, high level of noise and vibration, high voltage power transmission, heavy friction, acceleration or kinetic energy... all are sources of great danger. They demand high cost of expenditure, consume more material and energy, make more pollution and always pose high risks in all directions.

Therefore it is in the interest of safety, health and environment to run the plant at minimum required level of inputs of energy, storage of materials, process parameters, speeds of machines and generation of chemical exposure, noise, vibration, radiation (including heat, light etc.), pollution, test conditions and so many areas of energy utilisation. An effective energy conservation programme should be worked out by technical experts and consultants, should be implemented at all levels and monitored continuously for expected results.

India has 16% of the world population but less than 1% of the world energy resources. More than 50% of the oil is imported. With large foreign debt, the rupee will be always weak and import of any form of energy like Coal, Oil or Gas will be a difficult proposition. Hence efficient use of all forms of energy is very important. For electricity, it is of particular importance as 70% of the power generation is thermal. Efficiency of thermal generation is 35%. With T & D losses of 20 to 25%, saving of I unit of electricity at user's end, leads to saving of 4 units of primary fuel.

In developed countries, industries have improved energy efficiency by 30 % .to 40%. Energy efficiency improvements have been gained by all types of industries like steel, chemical, cement, paper, engineering, textile, food etc.

In Gujarat and Maharashtra the Electricity Costs for industries is about Rs. 4.00 per unit (KWH). It may reach Rs. 5.00 in few years. Energy costs and profits are of the same order of magnitude in many industries. Reduction in energy costs can lead to significant improvement in profit. Some Indian industries have also achieved significant energy savings by systematic efforts. Proper selection of the equipment with better efficiencies, which are available in the market and proper design of the associated systems for operating at optimum efficiency are very important for obtaining energy economy. After the plant is stabilised and all major parameters are known, a second look at the system design may be rewarded with lot of savings at low cost.

For an effective energy saving program, a well trained team of plant personnel is the first and foremost requirement. You too can achieve Large Energy Savings by exposing your managers and engineers to the ideas and methods of improving energy efficiency.

An electrical energy conservation training programme may include following .or similar subjects:

1. Systems Approach to Efficient Use of Electricity.
2. Energy Accounting, Monitoring & Control.
3. Methods for Energy Efficiency Improvement.
4. Electric Motors/Starters/Efficiency Testing Methods.
5. Pumps & Fans.
6. Variable Speed Drives.
7. Electric Heating/Melting.
8. Thermal Insulation.
9. Electrolytic Processes.
10. Illumination.
11. Compressed Air.
12. Refrigeration.

13. Cooling Towers.
14. Maximum Demand/Power Factor Control.
15. Transformers & Cable Losses.
16. Cogeneration.
17. Management of Energy Conservation.
18. Information on Suppliers.
19. Case Studies.

As a result effective measures should come out as minimum energy inputs, savings of electricity, heat, steam, water, air etc. and optimum use of controlled energy.

See Energy Conservation Act. 2001 and Rules 2005 for more information. Guidelines from Mines and Energy Department are available. At every three years Energy Audit Report is to be submitted. Energy Manager is also to be appointed.

Industries should try to get the National Energy Conservation Award.

EXERCISE

1. Explain, State, Mention or Discuss :

1. The statement 'Electricity is a friend of men but it can become an enemy too'.
2. The safety provisions under the Electricity Act 2003 or those under Electricity Rules 2005.
3. What are the points insisted upon by the National Electric code ? OR State seven parts contained by it.
4. What do you mean by physiology of electric shock ? State main causes of electric shock on human body.
5. The effect of electric current or voltage on human body.
6. The effect of mains voltage (230 V) on dry and wet skin by an example.
7. What are the general precautions for safety in electric work ?
8. Major safety measures for electric work.
9. What are power cutting devices ? Explain safety requirements in their design and use.
10. Types of protection for electrical safety.
11. What do you mean by protective earthing ? Explain the part to be earthed and methods of earthing.
12. What is the meaning of 'no load condition?' What are the hazards of low (insufficient) current ? What are the safety measures for this?
13. Why ELCB is called an electric shock guard ? Explain its working.
14. Why earth, insulation and continuity tests are necessary ? Explain the reasons.
15. The meaning and types of earthing. Mention the standards of earthing.
16. What are current surges ? When do they occur? What are the protections against them?
17. Neutral connection system and safety aspect of it.
18. What do you mean by lightening arrestor'? Explain its arrangement and working.
19. The safety aspects of portable electrical apparatus.
20. Indian Standard and its classification of hazardous areas for electric work.
21. Type of flameproof electrical equipment necessary for three classes of hazardous
22. List different types of flameproof equipment and explain the utility of any five of them.
23. The phenomenon of static electricity and types of static charging.
24. Where bonding is not necessary to protect from static electricity ?
25. Various operations and machines generating static electricity.

2. Write Short Notes:

1. Type of electrical hazards.
2. National Electric Code.
3. Electric shock.
4. Personal sensitivity to electric shock.
5. Factors affecting severity of electric shock on man and woman.
6. Effect of electric shock on heart and other body parts.
7. Electric burns.
8. Threshold shock voltages at 50 c/s.
9. Effect of increasing voltages on body resistance.
10. Lock-out & Tag out.
11. Methods of protection for electrical conductors and connections.
12. Overload and short circuit protection .
13. Thermal protection.
14. Good earthing or Double protection.
15. Earthing for machine tools.
16. ELCB.
17. Earthing standards.
18. Earthing of portable power tools.
19. Voltage fluctuation and protective devices for it.
20. Hazards of borrowed natural.
21. Hazard and safety aspect of portable transformers.
22. Hazard area classification and its usefulness.
23. Safety measures for low and high risk areas of electric work.
24. Hazards of static electricity.
25. Control measures for static electricity.
26. Operations generating static electricity and specific control measure for their operation.

CHAPTER – 12

Noise and Vibration

THEME

Part A : NOISE

1. GENERATION, PERCEPTION, NATURE AND TYPES OF NOISE

Speech or communication is an essential need of human life and that is not possible without voice or sound.' Complete deafness takes away the charm of life. Poor hearing in old age creates problems. Poor listening induces loud speaking or shouting. Thus good listening or hearing capacity is -very much required throughout the life. Vibrations of air particles cause sound and make the communication possible.

But everything in excess is always harmful. vfr loZ= otZ;sr~ Unbearable sounder noise creates difficulty in communication and causes mental and physical stress resulting in illness and accidents.

Sound is a useful communication or pleasant sounds viz music, speech, while noise is a discord or unpleasant sound.

Centuries ago, in 1700, Ramazzini described deafness and hard hearing of workers who were hammering copper.

No more people were exposed to high noise before the Industrial Revolution. With the advent of steam power, attention was attracted towards noise as a hazard. Workers engaged in fabricating steam boilers were found to develop hearing loss which was termed as boilermakers' disease. Day by day mechanized industries increased with the effects of intense, mixed and complex noise levels at work places. General outside environment also became noisy.

The modern life of many types of industrial noise, high volumes of musical sound, noise due to vehicles and transports and addition of constant noise in environment front variety of sources have generated a Noise Problem. Throughout the world noise (unwanted sound) is considered as an environmental pollutant and statutory provisions are made to control it.

1.1 Generation of Sound / Noise:

Sound is an acoustic vibration generated due to movement of particles of an elastic medium (e.g. air, liquid, metal). Sound produces an auditory sensation between 16 Hz to 20000 Hz frequency range.

Physicians define noise as a superposition of sounds of different frequencies and intensities without any phase correlation. Physiologists consider noise as any unpleasant or disturbing sound.

Environmental noise is a noise of measurable intensity such as is normally noticed in workplaces.

Sound wave is generated when any object vibrates in air (or other medium) and the disturbed air particles spread away from the object in the form of a wave. See Fig. 12.1.

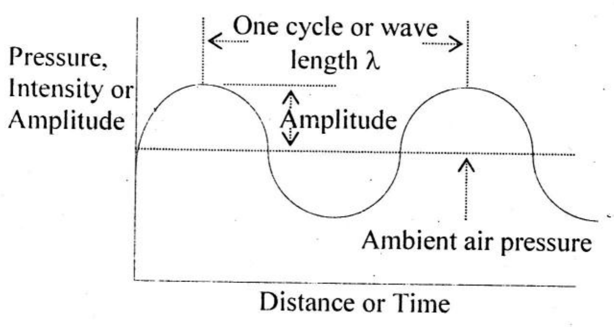

Fig. 12.1 Sound Wave

These waves in turn impinge on our ear drum and set it in vibration. Moving fluid and thousands of hair cells inside the car convert the vibrations into nerve impulses which are carried to the brain where the impulses are converted (interpreted) into what we hear as sound.

Mode of Sound Propagation:

Sound propagation in air is like ripples in silent water. Ripples spread out in all directions uniformly, ' decreasing in amplitude as they move away from the source.

For sound in air when the distance doubles the amplitude drops by half, thus following the inverse square law.

Thus if you are at a distance of 1 mt away from source of sound and move 1 mt further away from die source, the sound pressure level {SPL) will drop by 6 dB. If you move to 4 mt, it will drop by 12 dB, to 8 mt, drop by 18 dB and so on. This is true only when there are no reflecting or blocking objects in the sound path. Such ideal conditions are called Free Field Conditions.

With obstacles in the path of sound, part of sound will be reflected, part absorbed and remainder will be transmitted through the objects. How much sound will be reflected, absorbed or transmitted depends upon the properties of the object, its size and wave length of the sound. See Fie. 12.2.

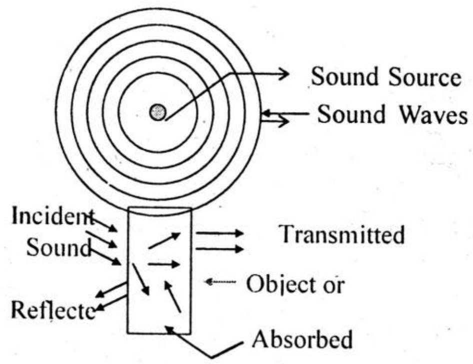

Fig. 12.2 Propagation of sound

In general, the object must be larger than one wave length in order to significantly disturb the sound. For example, at 10 KHz the wave length is 3.4 cms, even a small object will disturb the field, sound absorption and insulation are readily achieved. But at 100 Hz sound frequency the wave length is 3.4 mt and sound insulation becomes much more difficult.

1.2 Perception of Sound/Noise :

It is the human ear which perceives or hears the sound and sends the message to the brain through senses.

The human car is shown below in Fig. 12.3

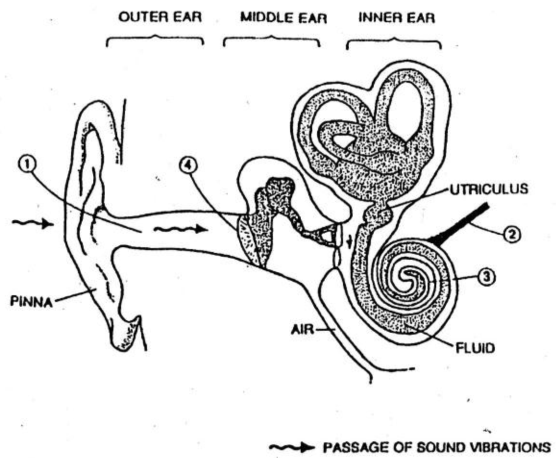

Fig 12.3 Human Ear

The ear has 3 parts - outer ear, middle ear and inner ear. The outer ear contains the external auditory canal which carries sound waves to the eardrum (tympanic membrane). The middle ear has eardrum and hammer which vibrate due to sound waves. This assembly transmits sound waves to the-inner ear after amplifying or diminishing the sound to protect the inner ear, thus regulating the sound level. Two muscle tighten the eardrum and give acoustic reflex as per brain's command. Due to high noise or many years o) hearing, these muscles weaken resulting in hearing loss.

The inner ear is a complex system of bony fluid-filled crevices and is responsible for our sense It sends message to the brain.

1.3 Nature and Characteristics of Noise

Noise is a sound but it is unwanted o undesired sound i.e. a sound without agreeable musical quality. It is an annoyance and interfere with work efficiency and causes accidents, hearing loss or deafness depending upon its type and period of exposure. Glorying and Wheeler's study show that the greater the length of exposure, the is the degree of hearing loss, especially in 4000 to 8000 c/s frequency.

Sudden and loud noise produces high reactions in all persons and loud and persistent noise (of high pitch) may produce deafness. Such noise should be eliminated if possible, otherwise, avoided by ear-protection.

The sound wave has following characteristics and relationships:

Frequency:

It is the number of pressure variations (vibrations) above and below atmospheric pressure (760 mm of Hg) i.e. the rate at which complete cycles of high and low pressure regions are produced by sound sources. Its unit is cycles/sec or Hertz (Hz). Normally human ear registers frequencies from 2020000 Hz. This is known as the audible range of frequencies. Frequencies below 20 Hz are called infrasonic and above 20000 called ultrasonic. Ear is most sensitive between 1000 to 4000 Hz and damage occurs above 4000 Hz. The instrument used to measure sound frequency is known as octave band analyser.

Wave length:

The distance required to complete one cycle of pressure is called one wavelength (X) or a distance between two crests or troughs of the wave

$$\text{Wavelength (h)} = \frac{\text{Speed of sound (S)}}{\text{Frequency (F)}}$$

where speed of sound = 344 m/s or 1130 ft/sec.

Period:

It is the time required to complete one pressure cycle and is reciprocal of frequency. It is measured in seconds (T).

Sound Intensity (1) or Amplitude:

It determines the loudness (though both are not same) and measured in terms of decibels (dB). At a specific location, the sound intensity is the average rate at which sound energy is transmitted through a unit area normal to the direction of sound propagation.

Intensity is the pressure or energy that the shunted air particles deliver to an ear. It falls off with distance and is given by the decibel or dB which tells us how many times bigger the intensity of a particular sound is than the intensity of the reference sound at the bottom of the scale. 'dBA' refers to sound level in decibels as measured on a sound level meter operating on a - weighing network (reference) with slow meter response.

Loudncss is the sensation produced in the human ear. It depends on the frequency and intensity of sound. Loudness levels in 'phons' of some industrial operations are given below (IS:3483) : In table 12.1

Table 12.1 : Loudness level of industrial operations

Industrial operation	Loudness in phons
Textile mills	90 to 110
Sugar mills (crushing)	105 to 110
Steel rolling	95 to 105
Drop forge hammer	130 to 145
Steel bar shearing	110 to 125
Riveting (steel plates)	105 to 110
Circular saw (wood)	100 to 110
Wood planning	115 to 120

Phons units of loudness are expressed on a logarithmic scale, while, **sones** units are expressed on a linear scale. Loudness level varies with different individuals and also with the two ears of the same individual.

Sound is usually measured in groups of frequencies. A convenient grouping is f_0,-$2f_0$, $2f_0$-$4f_0$,$4f_0$-$8f_n$ etc. These are called octave bands.

A sound with a rating of 2 sones is considered to be twice as loud as one of I sone.

Frequency is related to pitch and intensity is related to the loudness of the sound. Pitch refers to the quality of sensation of sound whereas loudness refers to the quantity of sound. Higher the loudness, higher is the intensity. Higher the pitch, greater is the potential to cause annoyance.

The audible range of young and healthy person is

0 dB (0.00002 N/m^2 or 20 uPa) - Threshold of hearing
130 dB (20 N/m' or 10-12 watts Threshold of pain

The dB scale is logarithmic and instrument used to measure sound intensity is called precision sound level meter.

Sound Pressure:

It refers to the root mean square value of pressure changes below and above the atm. pressure. Units are microbar or dyne/ cm^2, N/m^2 or Pascal. 1 µbar = 1 dyne/cm^2 = 0.1 N/m^2 = 0.1 Pascal.

See Fig. 12.4 for relationship between dB and Sound Pressure levels.

Sound Power:

It is the sound energy produced per unit time. Power is expressed in watts (W).

Sound intensity is also defined as sound power per unit area i.e. 1 =W/a.

See Fig. 12.5 for relationship between dB and Sound Power levels.

Inverse Square Law:

Sound travels in all directions from source and sound power is given by

$W = I \times a = I \times 4pr^2$

where a is the area of sphere surrounding source over which intensity is averaged. Hence

$I \alpha l/r^2$

Thus intensity is inversely proportional to the distance (radius r)

The louder the noise and the higher its frequency, the more damaging it can be.

Levels of some common sounds:

The sound levels (pressure) in both the units are given in Table 12.2

Table 12.2 Some Common Sound Levels:

Sound Source	Sound Pressure	
	dB	N/m^2 (Pascal)
Threshold of excellent hearing	0	0.00002
Threshold of good hearing	10	
Whisper	20	0.0002
Recording studio	30	
Average residence	40	0.002
Private office	50	
Conversational speech	60	0.02
Noisy office	80	0.2
Factory	90	
Passing truck	100	2.0
Punch press	110

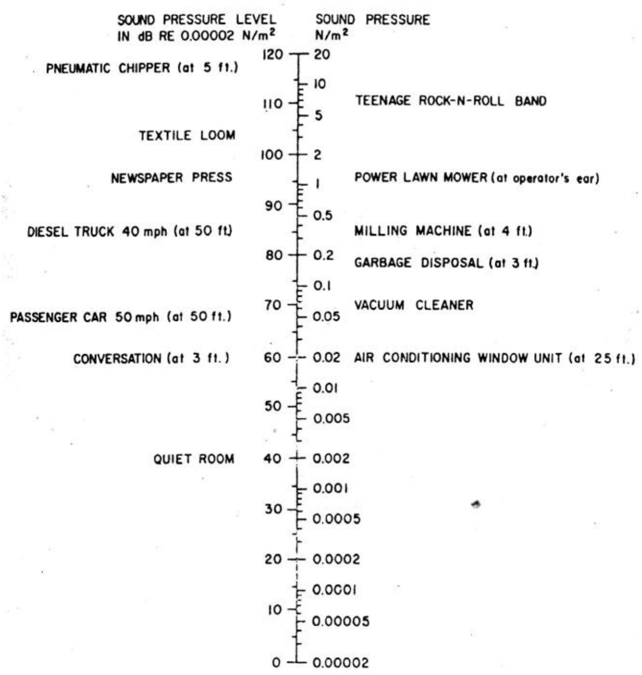

Fig. 12.4 Relationship between A-weighted Sound-Pressure Level in Decibels (dB) and Sound Pressure in N/M^2.

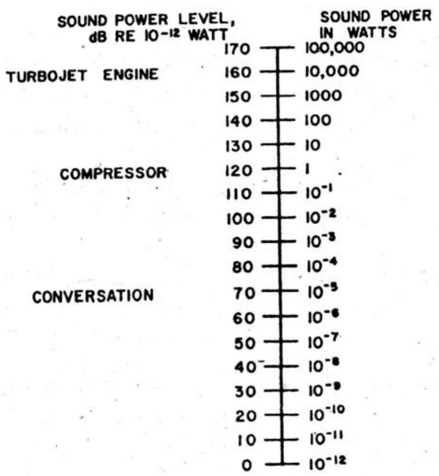

Fig. 12.5 Relationship between Sound Power Level in Decibels (dB) and Sound Power in Watts.

1.4 Types of Sound / Noise :

Sound or Noise is continuous when the source is constantly vibrating, e.g. motorised bell. It may be impulsive when the source causes vibration only for a short time e.g. sound from a drop forge hammer, explosion or a rifle shot.

Third category of sound is classified as fluctuating sound. In a large workshop where numbers of machines are in operation, noise level varies from time to time. As a result the noise pattern produced throughout the day is plotted. Then equivalent continuous level should be measured as a mean of fluctuating level.

2 EFFECTS AND HAZARDS OF NOISE

Moderate sound (F < 4000 Hz) is good but high sound or noise is hazardous.

The harmful effects of noise depend upon a number of factors:

1. Noise frequency and intensity.
2. Total length of exposure.
3. Length of exposure at a time.
4. Distance from the noise source.
5. Whether noise is continuous, interrupted, sudden or impulsive.
6 Whether ear protector is worn or not and
7. Individual susceptibility depending on age, health etc.

Excessive noise harms overall health and may contribute to -

1. Mental stress
2. Physical stress
3. Certain illness
4. Hearing Loss or deafness
5. Accidents and
6. Labour productivity.

Labour productivity is declined when workers are exposed to high noise level.
The harmful effects of excessive noise have been well recognised and it has been shown that such noise produces physiological and psychological effects on industrial workers, such as hearing loss, deafness, fatigue, irritation, annoyance, distraction, masking. Such effects are due to sound intensity.

J.L. McCartney's report 'Noise drives us crazy' shows that the work of assembling temperature regulators increased more than 37% and errors fell to one-eighth of their former number when the work was moved from the proximity of a boiler shop to a quiet area. Office work increased 8.8% and typists' errors fell 24% with a noise reduction of 14.5%. The noise reduction also decreased turnover or workers by 47% and absenteeism by 37.5%.

In factory where audible warning signals are to be heard or where an operator has to follow the operation of his machine by ear, the background noise should not be so loud as to mask (suppress) the signal or desired sound i.e. information sound to he heard.

Another noise criteria, known as Damage-Risk Criteria specify the maximum levels and duration of noise exposure that can be considered safe.

Whenever the noise intensity at the workers position exceeds the levels and duration suggested by the criterion curves, ear protection is recommended, since such exposure may cause permanent auditory damage.

Noise induced hearing loss is not ameliorated by the use of hearing aid. It may rather accentuate the frequency distortion.

Auditory ill-effects are of two types - temporary (threshold) hearing loss and permanent hearing loss including physical damage (ruptured eardrums). For details see Part 2.1.

Non-auditory ill effects are vibration or change in blood pressure or/and respiration or digestive system, dilatation of pupils and diseases like peripheral vascular disturbance IDH, vascular neuropathy, myopathy etc. Impulsive noise disrupts work performance. Continuous noise may have subtle psychological and psychomotor effects.

Speech or hearing interference (masking), annoyance, distraction, fatigue (mental and physical both), muscle tension, headache, nausea, tiredness, nervousness and contribution to other disorders are also reported. For details see Part 2.

If noise cannot be reduced at source, or its transmission to the environment cannot be prevented, use ear protection.

Exposure to excessive noise raises our hearing threshold i.e. the degree of loudness at which we first begin to hear.

Some health effects are discussed in details below:

2.1 Auditory Effects (Hearing Loss) :

These are serious health hazards resulting in hearing loss or deafness.

Hearing Loss:

Hearing ability can be greatly reduced by repeated or long exposure to high noise and this permanent effect is known as noise induced hearing loss.

It is impairment in ear that obstructs receipt of sound and understanding of speech in a sentence form (not in the form of test words). It is deafness. It is irreversible and incurable disease and can be corrected partly by hearing aids. Early audiometric examination can prevent further damage.

A young person with normal hearing can easily detects sounds in 6 to 20000 Hz frequency range. Important frequency range to understand speech is between 500 to 2000 Hz. Generally hearing losses in this frequency range which are compensable under Workmen's Compensation Laws.

Old definition of 'hearing impairment (loss)' means to begin to hear (threshold level) at 25 decibels more at 500, 1000 and 2000 Hz.

Ability to hear less than normal speech indicates degradation. It can result from ageing, long-term exposure to high noise (more than 90 dBA) or from a sudden, very high intensity noise (more than 160 dBA). Much of this degradation with age may be due to continuous exposure to environmental noise of modern society rather than to simple ageing. It is possible therefore that even where a factory complies with standards (say 90 dBA), workers will suffer hearing loss (due to exposure outside) and be eligible for benefits under Workmen's Compensation Laws. Therefore it is advisable to avoid loss claims, all attempts should be made to reduce noise to the lowest possible level and not to be higher than 80 dB.

One of the more extensive studies involving 400 men, 90 women and a period up to 40 years has been reported by LL Beranek and LN Miller, in 'The Anatomy of Noise', Machine Design, 14-9-1967. The group was regularly exposed to noise of 90 dB in each of the six octave frequency bands between 150 and 9600 Hz.

The study found that appreciable hearing losses at 3000, 4000 and 6000 Hz occurred in the first 15 years. At 500, 1000 and 2000 Hz, hearing losses increased less rapidly, as linear functions of exposure time. Some of the men tested, even at 30 years young, found it difficult to understand speech after about 10 years of exposure.

Men showed greater hearing loss than women because the women had regular work breaks during each shift while the men did not.

The ear's greatest sensitivity is in the 30005000 Hz range and hearing loss almost always occurs first at about 4000 Hz. With time and continued exposure, the loss extends to a range of 3000 to 6000 HZ. This diminishes hearer's ability to follow conversation. The most important frequencies for speech comprehension are at 500, 1000 and 2000 Hz. Therefore tests for hearing losses are made at these frequencies for compensability. The lowest level at which a person (under test) can detect sound is called hearing threshold. A loss is considered compensable if the degradation in hearing is 15 dB or more in speech frequencies. 'This means that the hearing threshold has been increased by at least that amount.

Effects of Chemicals on Hearing loss are also reported. Exposure to certain chemicals, along with noise, can also cause hearing loss. Toluene, lead, mercury, arsenic, CS, manganese, n-butyl alcohol, trichloroethylene, styrene are reported for such effect.

It is also reported that noise above 115 dBC (i.e. ceiling level) as 8-hour TWA and 155 dBC as peak exposure (impulsive or impact noise) to the abdomen of pregnant workers, beyond the fifth month of pregnancy may cause hearing loss in the fetus.

In such combined effect of noise and chemicals, periodic audiograms and their careful review are necessary.

A very loud impulsive noise can cause ringing in the ears (tinnitus) and immediate loss of hearing sensitivity. It can disappear if there is no further exposure to high noise levels. The impulsive or impact level should not exceed a ceiling limit of 140 dB (OSHA).

The ear can protect itself to some extent from noise by means of the reflex contraction of certain muscles in the middle ear which tries to limit the energy being transmitted inside. This protection is of little use when sudden very loud noise strikes the ear causing the muscle fatigue.

Factors affecting degree and extent of hearing loss are as under:

1. The intensity of the noise (sound pressure level).
2. The type of noise (frequency spectrum).
3. The period of exposure each day (duty cycle per day).
4. The total work duration (years of employment).
5. Individual's susceptibility.
6. Age and health of the worker.
7. Co-existing hearing loss and ear disease.
8. Character of the surroundings in which the noise is produced.
9. Distance from the source, and
10. Position of the ears with respect to sound waves and wearing ear protection or not.

The first four factors are called noise exposure factors and are more important.

Because of so many factors i.e. possible contributory causes and complex relationship of noise and exposure time to threshold shift (reduction in hearing level), time required to establish criteria t(protect workers against hearing loss may last many years.

The signs and symptoms of hearing loss are

1. Ringing in the ear at the end of the work shift slight headache, tiredness, dizziness.
2. Intermittent ringing in ears.
3. Normal hearing is affected - if background noise is present, incapability of picking up conversation, cannot hear ticking clock etc.
4. Feeling of hearing insufficiency is manifest.

Reduction in hearing capacity is not on) quantitative but also qualitative, that is, sounds a; perceived in an abnormal manner.

Diagnosis and special tests include audiometric examination and monitoring noise levels at the work place.

Hearing loss is of two types - temporary and permanent . They are also classified as conductive sensorineural and mixed hearing loss.

Temporary hearing loss can be caused by exposure to loud noise for up to a few hours, which numbs the hair cells. Fortunately, hearing is usually restored after a period away from noise.

Permanent hearing loss occurs when exposure to loud noise permanently damages or destroys the hair cells. Hearing cannot be restored. Signs of permanent hearing loss include -

1. Inability to hear pitched or soft sounds.
2. Trouble in understanding conversation, or speech heard over the telephone.
3. Ringing or roaring m the ears (tinnitus).

Any condition interfering with transmission of sound to the cochlea (inner ear part) is classified as conductive hearing loss'. It can be due to wax in auditory canal holes in eardrum, blockage of Eustachian tube, fluid in the middle ear secondary to infection. This type of loss is also due to medical or surgical treatment.

Sensorineural hearing loss is mostly irreversible. It involves the organ of corti and degeneration of the natural elements of the auditory nerve. It indicates sever injury to the hair cells. This type of loss occurs due to various causes including presbycusis, viruses (e.g. mumps), some congenital defects and drug toxicity (e.g. streptomycin).

Mixed hearing loss occurs when above both the types of losses are found in the same ear.

Central hearing loss means person's difficulty to interpret when he hears. The abnormality is localized in the brain between the auditory nuclei and the cortex.

Psychogenic hearing loss indicates nonorganic basis for threshold elevation. It may be due to malingering and hysteria.

No cure exists for hearing loss caused by noise. Hearing aids do not restore noise damaged hearing, although they help some people if such aids are properly selected.

Exposure to intense noise creates a temporary threshold shift (TSS) first. This is greatest from 1 to 24 hours after the exposure and reduces gradually if the noise has not been too loud. or has not been too long. This condition is also known as auditory fatigue. This effect is transitory i.e. removable. It is of two types TTS, and TTS,,. The later persists beyond 16 hours.

Repeated exposures produce a permanent threshold shift (PTS). If no recovery is noticed within a week (i.e. no hearing improvement by then), a return to the level before exposure is improbable. It is a noise induced hearing loss.

While deciding whether a certain noise is a hazard, the important factors are both the sound level and the number of hours of exposure per day. Table 12.4 and 12.5 given in Part 4 must be followed for that.

Hearing loss is a notifiable Disease under the Factories Act 1948 :

Noise induced hearing loss (exposure to high noise levels) is a notifiable disease under the Third Schedule of the Factories Act and duty is cast upon both the manager of the factory and the medical practitioner attending the person affected, to report to the Chief Inspector of Factories without delay (Sections 89 & 90).

2.2 Non-auditory Effects:

These are the effects other than the hearing loss and mostly temporary in nature. They may be disappeared if their causative factors are removed.

2.2.1 Speech or Hearing Interference and Masking :

Oral communication is interfered by a noisy environment and misunderstanding may be created about information being transmitted. It can lead to accidents. Such sound effect is called masking.

Masking is a level in decibels, by which a sound must be increased to be understood in the presence of another, interfering sound.

Tests were conducted of reception of pure tone (single frequencies) communications, where masking was also provided by pure tones. It was found that the intensity of the message to be communicated had to be increased 15 to 30 decibels to become understandable.

Various methods to measure the effects of noise levels on speech communications are based on relationships among noise levels, voice (speech) levels and distance between speaker and listener.

2.2.2 Annoyance :

Normally people are annoyed by noise. However types and levels differ from person to person. Rock music annoys people who like classical music and vice-versa. Acclimatisation or tolerance to certain level is an important factor. People who have been exposed to certain noises over a long period develop a tolerance to that level. The same noises may annoy other persons who have not developed the tolerance and to such a degree their efficiency is degraded. They may become more prone to errors or accidents.

Normally louder noise or unexpected impulsive -noise can be more annoying. High frequencies are more annoying than low frequencies.

2.2.3 Distraction :

It is another noise effect that diverts attention of a person. For example/passengers talking with a driver of a bus can distract his attention which may lead to an accident. Persons talking in the vicinity can distract the attention of other persons even if it does not annoy them. The sudden ringing of a telephone or any audio signal can distract attention and disturbs concentration.

2.2.4 Physiological Effects :

Sleep disturbance (WHO report, even at less than 35 dBA) and stress reaction (e.g. jet aircraft personnel exposed to 120 dBA or more) have been noticed.

Cancer: A case study was published in 'Current Science' weekly. 40 female rats were kept under the effect of 25 kHz ultrasound waves daily for one minute and for a period of six months. In 70% of these test-rates, cancer tumours were observed, skin wrinkles were seen and their hairs fell off. They were feeling difficulty in movement and died earlier than normal rates. Dr. S.N. Chatterji of Nuclear Physics in Saha Institute and Dr. Pratima Sur of Indian Institute of Chemical Biology carried out this experiment and warned against this ultrasound hazard mostly found in equipment used for biological and medical diagnosis. (News 10-8-98).

Adverse effects on work output, efficiency and morale are another non-auditory effects of noise. Fatigue and mental health' effect may also occur. However such effects are varying and many a times human adaptability nullifies such effects.

2.2.5 Behavioural Effects:

Adverse effects on work output, efficiency and morale are other non-auditory effects of noise. Fatigue and mental health effect may also occur. However, such effects are varying and many a times human adaptability nullifies such effects.

2.3 Impact Case Studies :

Systematic noise measurement in work environment, audiometric examination of workers to detect hearing loss, study of correlation of occupational noise and its impact on man or any research work on such noise impact studies are most desirable.

In 1956, Robinson and Dadson had tested a group of 51 people of average 20 years are. Additional data were obtained by Muson on 8 men and 2 women with the average age of 24. Conclusions of this study

1. A characteristic known as minimum audible field (MAP) is obtained when young people of good hearing ability are tested.

2. At low frequencies (Hertz) the sound pressure level (dB) must be high before a tone (hearing threshold) can be detected. At high frequencies noise is audible at low pressure (dB) level. At 16 Hertz frequently, first noise is audible at ' 80 dB while at 12500 Hz it is audible at 20 dB.

3. The initial discomfort threshold starts at 120 dB (between 250 Hz to 7500 Hz).

4. The initial pain threshold starts at 140 dB.

In 1961, Gloring determined that permanent deafness at a frequency of 4000 Hz from daily exposures of 5 to 8 hours reached a maximum at @12 years of exposure.

Many studies have revealed that high noise levels can be tolerated if exposure time is decreased sufficiently. Table 12.3 in Part 3.4 indicates this effect

Experiments in laboratories have shown that the presence of continuous loud noises disturb the attention and increase the frequency of momentary lapses in efficiency.

Dr. Jansen of West Germany conducted a study of the psychological effects of noise on steel workers. Over 1000 workers were interviewed and tested. A group of 2/3 workers who were working in noise level above 90 dBA was compared to a group of 1/3 workers who were working in less than 90 dBA noise. The average worker was 41 years old and had been on his job for II years. Workers of both the groups were matched as closely as possible according to their economic, social and ethnic backgrounds. The results of comparison revealed that –

1. Workers who worked in less than 90 dBA were easier to interview than those who worked in more than 90 dBA noise.

2. Workers exposed to more noise were found more aggressive, distrustful and in some cases, paranoiac. A contributory cause of hearing loss was also noted.

3. Workers exposed to higher noise had more than twice as many family problems. Thus noise 'affects a worker's behaviour not only on die job, but at home also.

In the middle of 1950, Dr. G Lehmann and his team studied the effects of noise on human body by carrying out various experiments and concluded that

1 Noise has effect (shrinking) on small blood vessels, especially pre-capillaries. It makes them narrower. This effect is known as vasoconstriction.
2 Noise causes reduction in blood supply to various parts of the body.
3 Noise decreases the stroke volume of the heart thereby decreasing blood circulation in the body.
4 87 dB noise for 3 seconds constricted arterioles in the fingers and cut down the volume of blood by one-half. After the noise stopped, it took @5 minutes for the arterioles to fully recover.

Earlier experiments had noted the adverse effect of high noise on blood vessels which feed the brain, headache due to persistent noise and heart attacks. Noise wears down the nervous system, breaks down our natural resistance to disease and power of recovery thus lowering the quality of general health.

Noise impact studies are essential to know the effect of high noise of present day machinery like air compressors, diesel generators, high speed power looms, POY spinning machines etc. An industrial hygienist should be employed for this.

3 MEASUREMENT AND EVALUATION

3.1 Sources of Industrial Noise :

Before studying methods of measurement, it is necessary to know the main sources of industrial noise. They are:

1. **Impact :** It is the most intense and wide spread of all industrial noises. Impact noise is usually impulsive but it can be continuous as in case of tumbling. Operations like forging, riveting, chipping, pressing, cutting, weaving, tumbling and sheared steel plates falling one over another produce such noise.

2. **Friction** : Friction processes like grinding, sawing, sanding, cutting and turning on lathes and other machine tools, brakes and less lubricated bearings produce noise.

3. **Reciprocation :** Vibrating, reciprocating 'or unbalanced rotating machinery radiate noise and vibration directly.

4. **Air Turbulence :** High velocity air, steam or gases cause noise. The intensity increases with the velocity of the air stream. Examples are exhaust noise from pneumatic tools and jet engines.

5. **Other Noises :** In addition, there are other noises also, such as humming noise from transformers and whining noise from turbines.

3.2 Need of Measurement:

Measurement of sound provides definite quantities which describe and rate sound. This measurement can be useful in

1. Improving building acoustics.
2. Permitting precise, scientific analysis of annoying sounds, and
3. Giving a clear picture on identification of damage to hearing and suggesting corrective measures to be taken. Hearing loss can be determined by measuring a person's hearing sensitivity by audiometry.

3.3 Methods of Measurement :

IS:3483 describes following points :

Intensity levels in the different octave bands are measured by a sound level meter in conjunction with octave-band filters.

The noises are picked up by a high quality microphone, passed through an octave-band filter and the sound pressure levels recorded on a level recorder. Alternatively, noises recorded on a magnetic tape or the recording system has a substantially uniform frequency response over the entire audio frequency range.

Impact noise, which are highly complex in nature are measured with an impact noise analyser and also simultaneously recorded on a magnetic tape recorder to facilitate octave-band analysis. It is also sometimes displayed on oscilloscope screen.

As the noise levels are not the same at all locations inside the factory or workshop, the levels are measured mostly at locations enveloped by high integrity noises. Also while determining damage risk, it is necessary to measure the noise levels as close to the operator's ear position as possible.

The methods to be adopted to measure and assess the degree of noise hazard depend on whether the objective to be attained is to assess -

1. The hearing loss (auditory effect).
2. The interference with communication essentials for safety and productivity (Non auditory effect), and
3. The hazard involve in the task (to study a specific problem).

Standard methods and instruments should be used for measurement and the results obtained should be compared with threshold limits. See Table 12.3 in Part 3.4. National or International standards should be followed. 85 dBA is an alert threshold limit and 90 dBA a hazard threshold limit. Ear protector is must to work in exposure exceeding 115 dBA. When noise levels are evaluated, normal working conditions and circumstances causing the highest noise levels must be considered.

For measuring steady-state or continuous noise, the equivalent continuous sound level should be determined in dBA and frequencies be analysed as per standard methods.

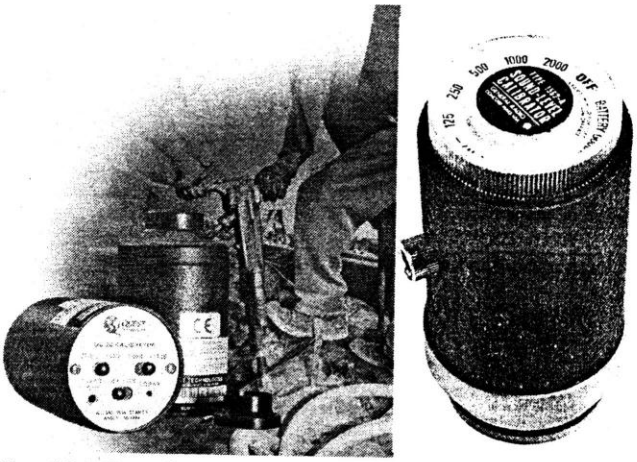

Fig. 12.6 Sound Level calibrator.

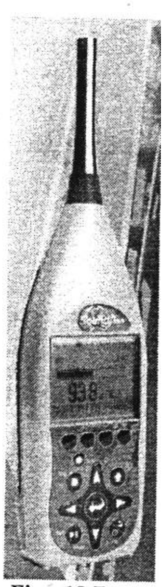

Fig. 12.7
Sound level

Impulsive or non-steady-state noise is I measured either by using sound level I meter in 'impulse' position and I calculating mean value of 8 hour per day, or by applying positive correction factor, generally 3 to 10 dB added to the slow response values, and then choosing the higher result.

Risk areas for measurement can be selected (1) Where noise hazard is liable to be present (2) Supervision, inspection or medical examination suggest that there may be a noise hazard and (3) Workers complain such inconvenience to them.

Where speech communication at normal voice is interfered at a distance of 50 cm, noise level should be assessed .

The noise levels should be measure) at a height of @ 1.5m above the work floor and at distance of at least 1 mt from the walls. It is advisable to establish the mean value of the sound level recorded in different directions.

Noise level should be measured at the worker' head level in his normal work posture or at a distance of I m from either side of his head position.

A noise chart should be prepared of the area where the measured noise levels are equal to or in excess of 80, 85, 90, 100 and 115 dBA. The Measurement Report:

A very important part of sound measurement is careful documentation of the measurements and result A good measurement report should contain at least the following information.

1. A sketch of the measurement site showing applicable dimensions (e.g. size of room machine dimensions), the location of the microphone and object being measured.
2. Standard(s) to which measurements are made.

3. Type and serial number of instrument (s) used.
4. Method of calibration.
5. Weighting networks and detector responses used.
6. Description of type of sound (e.g. impulsive continuous, tones etc.).
7. Background noise level.
8. Environmental conditions (e.g. type of sound field, atmospheric conditions).
9. Data on object being measured (e.g. machine type, load, speed etc.).
10. Date when measurements were performed.
11. Any other information.

With a carefully written report, future comparisons will be more accurate and reliable.

Noise Dose Measurement:

Fig. 12.8 Personal Noise Dose Meter

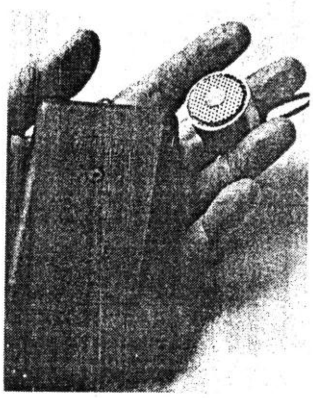

Fig. 12.9 Wearable noise monitor (battery-powered)

A noise dose is a measurement of noise or individuals who move between many different noise environments during the working day and can be obtained by using a noise dose meters.

Noise dose meter is a portable instrument which can be carried in a person's pocket. The microphone can be .operated from the noise dose meter body and should be mounted close to individual's more exposed ear.

Noise dose meters display the percentage of daily allowable noise dose. Personal noise dose meters are miniature integrate sound level meters. They directly measure the noise continuously and at the same time read out (display) noise does as a percentage of maximum allowable (100%) over an exposure period of 8 hrs. Beside this it also indicates when certain levels are exceeded i.e. 115 dB(A) maximum allowable and 140 dB(A) peak.

Discretely varying Noise Levels :

Many employees are exposed to a certain number of discretely varying noise levels usually because the noise is cyclical or varies stepwise at their work station or because the job requires them to move around the department or plant.

Noise codes describe procedures for summing a series of partial doses that such employees receive during their working period. Take a simple ISO example where an employee is exposed to 90 dB(A) for half of his working period and to 93 dB(A) for the remaining half. Since full working periods at 90 and 93 dB(A) represent doses of 100 and 200% respectively, half period doses are accordingly 50 and 100% giving a total dose of 150%.

In addition OSHA and many other national standards impose an overriding limit of 115 dB(A) "S" which should never be exceeded for any length of time.

One method of determining the noise dose of mobile employees is through the job-study interview. First/ a noise survey is conducted throughout the factory to determine the noise level at each working location. Then each employee is interviewed to determine what locations he works at and for how long. This rapidly leads to the determination of noise doses received by a large number of employees, furthermore periodic updates can be performed quickly. The job-study interview method readily lends itself to computerised record keeping. It is also a valuable aid for setting priorities in noise control schemes by identifying locations where the noise doses are excessive. A record form may be of the following type:

Employee noise exposure record

Employee name ______________________________

Date ____________________ Signed ____________________

Interview		Computation iso		
Work location	% time	Db (a)	8 hr dose	Partial dose *
A-5	60	85	30%	18%
A-8	5	95	315	16
B-21	10	88	60	6
D-13	25	91	125	31
	100			
			Total dose	71%

Recommendations :
Within ISO limits

$$\text{* Partial dose} = \frac{\text{\% Time}}{100} \times \text{8 hr dose}$$

3.4 Permissible Limits of Noise and Evaluation :

The recognition, evaluation and control of noise hazards include -

1. Setting objectives for a noise abatement programme.
2. Measurement of noise levels at workplaces and also with a moving man by measuring his doses of exposure.
3. Comparing the measured values with the permissible exposure limits and assessing the situation whether within limit or needs control measures (90 dBA under GFR).
4. Controlling exposure of excessive noise, and
5. Monitoring the hearing of exposed persons.

First three steps are 'evaluation' and the last two steps call for engineering control measures, audiometric and hearing conservation programmes.

First the company must decide the objectives to search for noise levels, to measure them by appropriate instruments and methods and by measuring levels at workers' ear levels, to set damage-risk criteria, to follow legal criteria and by comparing the measured levels with the desired (legal) levels to plan, design and implement the control measures.

The purpose of damage-risk criteria is to define maximum permissible noise levels in the hearing levels of exposed workers during their working life-time. Legal criteria should be accepted. See Tables 12.5 to 12.8 in Part 4.

As mentioned ACGIH booklet, TLVs for noise to prevent a hearing loss at higher frequencies such as 3000 Hz and 4000 Hz are given in Table 12.3.

Table 12.3 : TLV for Noise (ACGIH, 2007)

Duration per day (exposure time)		**Sound level dBA (TLV)**
24	Hours	80
16	Hours	82
8	Hours	85
4	Hours	8/8
2	Hours	91
1	Hours	94
30	Minutes	97
15	Minutes	100
7.5	Minutes	103
3.75	Minutes	106
1.88	Minutes	109
0.94	Minutes	112
28.12	Seconds	115
14.05	Seconds	118
7.03	Seconds	121
3.52	Seconds	124
1.76	Seconds	127
0.88	Seconds	130
0.44	Seconds	133
0.22	Seconds	136
0.11	Seconds	139

In measuring above values, standard sound level meter or dosimeter is to be used arid no exposure above 140 dB is permitted. The meter response should be kept slow. A dosimeter or integrating sound level meter should be used for sounds above 120 dB. Exposure is to be limited by noise source and not by administrative control. Method and formula to calculate the combined effect of two or more periods of noise exposures of different levels are also suggested.

The TLVs in Table 12.3 should be used as guide in the control of noise exposure and due to individual susceptibility. They should not be regarded as fine lines between the safe and dangerous limits. The TLV cannot protect all workers from the adverse effects of noise exposure. It can protect the median of the workers against slowly growing hearing loss.

It must be noted that a hearing conservation programme with audiometric testing is necessary when workers are exposed to noise at or above the TLV levels.

Hearing impairment should be evaluated in terms of a worker's ability or inability to hear speech under daily conditions. To hear sentences and to repeat them correctly indicates good hearing ability. Workers working in a noisy environment should be regularly checked for any detrimental effect on their hearing.

The critical factors to analyse noise exposures are 1. A weighted sound level.
2. Frequency composition or spectrum of the noise. 3. Duration and distribution of noise exposure during a typical workday.

Most of the industrial noise falls within 70 to 115 dBA. Below the lower level (70 dBA) it is safe and above the upper level (115 dBA) it is unsafe. In addition, type of noise and duration of exposure must also be considered. Hearing loss is directly related to total exposure time and the continuous exposure.

Table 12.4 shows the Acceptable Exposures in

dBA as a function of number of occur exposures per day.

°\ A variety of sound measuring insh'urntPP e>»-

A variety of sound measuring instruments are 1 available such as sound level meters, octave band! analysers, narrow band analysers, sound survey meters, tape and graphic level recorders, impact sound level meters and equipment for calibrating these instruments. Of these, the first two provide ample information.

A sound level meter is used to determine the noise exposure at the test time at a particular place. A noise dosimeter (to be worn by the worker) can be used to determine the exposure pattern of» particular individual. Octave band analyser is used to determine where the noise energy lies in the frequency spectrum.

Sound measurement falls into two main divisions, source measurement and ambient noise measurement. A source may be a single piece of noise or a combination of equipment or systems or even an entire plant. Ambient noise measurement ranges from studying a single sound level to making a detailed analysis showing hundreds of components of a complex vibration.

Thus by measuring high noise levels at work places and interrogating workers regarding hearing difficulty if any and carrying out noise surveys, noise values are evaluated and their effects are also determined by audiometric tests on workers. This suggests the necessary steps for noise control. For assessment of measured values and control measures, statutory provisions and IS are useful.

4 STATUTORY PROVISION

In the 3rd Schedule under the Factories A 'Noise induced hearing loss' (exposure to high noi levels) is included as a notifiable occupational disease

Schedule 23 u/r 102 of the Gujarat Factories Rules, defines high noise as 90 dBA or more and requires that -

1. No worker should be exposed to high noise level.

2. Ear protectors should be given to workers if engineering control to reduce noise is not possible and

3. Workers exposed to high noise should be auditory examined by a doctor within 14 days of his first employment and thereafter re-examined once in every year.

Schedule 24 u/r 114 of the Maharashtra Factories Rules 1963 and Schedule 28 u/r 95 of Tamil Nadu Factories Rules 1950 give table of permissible levels that are reproduced in Table 12.5 & 12.6 as under :

Table 12.5 : Permissible Exposure in case of Continuous Noise (also. OSHA standards)

Total time per day in hours	Sound level dBA
8	90
6	92
4	95
3	97
2	100
1.5	102
1.0	105
0.75	107
0.50	110
0.25	115

No exposure is permitted over 115 dBA.

Table 12.6 : Permissible Exposure of Impulsive / Impact Noise

Peak sound level in dB	Permitted number of impulses or impacts per day
140	100
135	315
130	1000
125	3160
120	10000

No exposure is permitted over 140 dB peak sound level.

Under Schedule VI Part E (u/r 3A) of the Environment (Protection) Rules, 1986, Noise Standards are prescribed as given in Table 12.7.

Table 12.7 : Noise Standards (after 1-4-2005)

A	Noise Limits for Automobiles, at the manufacturing stage	dBA
(a)	Two wheelers (80 cc to 175 cc)	75-80
(b)	Three wheelers	77-80
(c)	Passenger Vehicle (> 3.5 ton)	78-80
(d)	Good Vehicle (up to 3.5 ton)	76-77
(e)	Goods Vehicle (> 3.5 ton)	77-80
B	**Domestic appliances and Construction equipment at the manufacturing stage**	**dBA**
(a)	Window Air Conditioners 1-1.5 T	68
(b)	Air Coolers	60
(c)	Refrigerators	46
(d)	Compactors (rollers), Front loaders, Concrete mixers, Cranes (movable), Vibrators and Saws	75

Sch. Ill u/r 3 of the above rules prescribes noise levels in public areas as given in Table 12.8.

Table 12.8 : Noise Level in public areas (EP Rules)

See similar table in Part 10.13 of Chapter-28.

5 INDIAN STANDARDS

Noise: Some IS on Noise are : Noise reduction in industrial building 3483, assessment of noise exposure. during work for hearing conservation purposes 7194, ear protectors 6229, 8520, 9167, sound insulation of non-industrial buildings 1950, noise by electrical machinery 6098, noise by road vehicles 3098, 10399, noise by machines 4758, noise abatement in town planning 4954, airborne acoustical measurement 9876, airborne noise from compressor 11446, airborne noise from pneumatic tools and machines 11702, from gas turbine 10534, from machine tools 10988, assessment with respect to community response 9989, permissible limits from rotating electrical machine 12065, sound level meters for motor vehicles 3931, general purpose 3932, noise levels on onboard ships 13161.

Acoustics noise test 9000 (part 21), acoustical design of halls 2526, acoustics in buildings, glossary 9736, acoustics emission testing, terminology 12710, sound system equipment 9302 and sound system for conferences 11456.

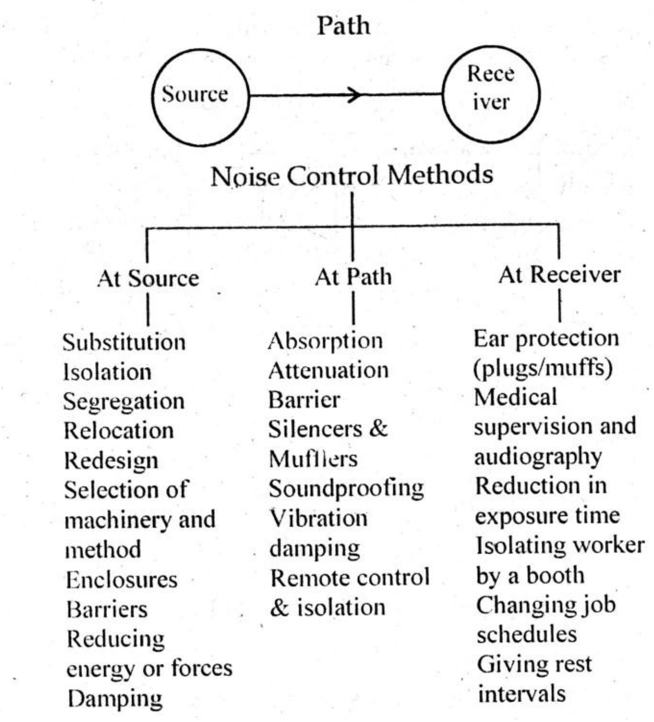
The first mentioned IS:3483 is very much useful to know-terminology, types of noise, frequency distribution, sources of noise, measurement of noise, methods of reducing noise and acoustical absorption devices.

6 CONTROL METHODS

First step is to measure the quantity and quality of noise by sound level meter, octave band analyser, sound dosimeter, audiometer or vibrometer. Control areas are the source, path and the receiver. Control methods should be aimed at

1. Controlling noise at sources.
2. Precluding the propagation, amplification and reverberation of noise, (path)
3. Isolating the workers (receiver).

Based on this, the control methods for prevention and reduction of noise can be classified as under:



6.1 Control at the Source :

Much noise can be eliminated by good engineering design. Wire mesh screens instead of sheet metal panels reduce vibrating noisy surfaces. Lining of absorbent materials would also reduce noise considerably. Machines can be mounted on rubber or other materials so that vibration and noise will be reduced. Quitter machine with plastic or rubber parts, lubrication, tuning and well maintenance give less noise.

Noise sources are of three types (1) Mechanical forces such as vibration of solid or liquid surface (2) Aerodynamic forces such as turbulence in air or gaseous environment and (3) Electrical forces such as electric arc or electric corona discharge.

Vibrations can be reduced by maintaining dynamic balance, diminishing the force causing vibration, reducing rpm, increasing duration of work cycle.

Response of vibrating elements can be reduced by increasing their damping power and improving fastening.

Liquid/gas flow rate should be reduced. Acoustic insulation on pipes can reduce 10 to 20 dBA.

Other measures include conversion of reciprocating movements into rotational movements, replacement of sudden stoppage by gradual braking, helical teeth instead of straight teeth on spur gears, prevention of impact of falling materials, installation of damping elements at points of contact between machine and plant elements, proper design of fan blades, proper tool and cutting speed in conformity with the material, proper design of air lines, ventilation ducts, gas mains and liquid pipes to prevent noise propagation, providing rubber tyres on trucks, trolleys etc., reduction in noise radiating surface area, machine guards of perforated sheet or wire mesh instead of plain sheet, reducing transmission of mechanical vibrations, inserting rubber or felt pads between the ends of the spring and the surfaces to which it is fastened, use of felt/cork as resilient mats or pads under machine bases, using isolators between the machine' and its foundation, heavy machines likely to cause impact noise should be rigidly mounted on massive concrete blocks having weights many times greater than the weights of the supported machines, loose and flexible connections in all pipes and conduits lending from vibrating machine, reduction in clamp sizes, use of sharp cutting edges, wobble dies in forging, quitter dies, use of anti vibrating mounts, mufflers for exhaust pipes and use of asphalt or tar for vibration damping.

Noisy machine may be placed in an enclosure or behind a barrier. A close-filling acoustic (insulated) box serves good purpose. The inside of the enclosure can be lined with sound absorbing materials. Bounding walls of enclosures should have adequate transmission loss to provide proper sound insulation (IS:1950).

Noise propagation can be controlled by installing machines on vibration-damping bases, using antivibration mountings and separate installation of noisy machines.

6.2 Substitution of Less Noisy Processes:

Examples are : Welding instead of riveting, mechanical forging instead of drop forging, grinding instead of chipping, belt drives instead of gears etc.

Other substitution includes hydraulic riveting instead of pneumatic riveting, grinding or flame gouging (20 dB) instead of chipping (120 dB), mechanical ejectors instead of air ejectors, slow acting process instead of high speed, hot working of metal instead of cold working, presses instead of hammers, rotating shears instead of square shears, belt drives for gears, pressing instead of rolling or forging etc.

6.3 Segregation and Isolation:

Noisy machines are removed to an area where few people work (segregation). Well insulated partition and tightly closing doors may be installed surrounding the machines (isolation).

Other isolations include providing a soundproof booth for the operator, separate location of noisy machines and processes from quiet ones -e.g. air compressor or diesel generator rooms should be separate and away from library, training centre, conference room, medical centre etc. Similarly office space should be segregated from the production area.

Equally noisy areas should be located together and segregated from quiet areas by buffer zones that produce and can tolerate intermediate noise levels.

Reflected sounds from ceiling and walls can be reduced by hanging isolators made of rubber, felt or cork.

6.4 Enclosure of Noise Source :

Noise producing operation can be enclosed or baffled in such a manner as to prevent dissipation of the noise into the surrounding area. Sound proofing by barrier structures.

Enclosures and barriers (partial or full, insulated or uninsulated, soundproof etc.) can curtail sound waves and reduce noise. More surface area of enclosure will reduce more noise.

A partial reduction of noise in certain directions can be obtained by one or more sided walls of barrier. Barrier wall facing the noise source should be coated with acoustic absorption material on that side to reduce noise appreciably. The barrier/enclosure opening should face a wall covered with sound absorbing material. If the top of the enclosure is open, sound absorbing material should be applied on the ceiling overhead.

Double wall with 10 cm intervening space is more effective than single partition of the same height.

Porous materials (e.g. porous concrete) can absorb more sound than rigid material.

6.5 Sound Absorption and Silencers:
(Acoustic Insulation)

High frequency sounds can be absorbed by applying sound absorbents to ceilings and walls in die form of acoustical tiles, plasters and blankets of porous materials such as glass wool. Acoustic baffles can be hung from the ceilings.

Reflection of sound waves from surfaces can be prevented by using absorbents which are usually porous materials that convert incident sound energy to heat. The amount of absorption depends on frequency and angle of incidence and can be expressed by the absorption coefficient which is die ratio of the absorbed energy to the incident energy.

A variety of absorbent materials are available for an acoustic engineer in the form of vegetable or asbestos fibres, glass or mineral wool and hard but porous plaster having less susceptibility to physical damage, fire resistance, light reflection, aesthetic qualities etc.

By sound absorbing walls, the operator near machine is not protected from noise, but the other workers working behind the walls would be benefited, particularly, if there arc reverberations 'in the building.

Application of acoustical material on ceiling and side walls, can reduce 3 to 8 dB noise level and bring down the general reverberate noise level to make the noise conditions less confusing.

Functional Sound Absorbers may be clustered as near the machines as possible. These units may be suspended and- distributed in any pattern to obtain lower noise levels within the machine shop. They are pyramidal or rectangular in shape. They use fibre glass as packing material. They have higher noise reduction coefficients than conventional acoustic materials placed directly on ceilings and walls. Noise reduction (absorption) coefficients are given in Table 12.9.

Table 12.9 : Noise Absorption Coefficients

Type	Coefficient for 250-2000 c/s
1 Flat area	
Fibre glass thickness	
2.5 cm	0.7
5 cm	0.93
2 Functional Sound Absorber	
(a) Pyramidal Shape	
Fibre glass	
Thickness	
2.5 cm	0.91
5 cm	1.39
(b) Rectangular shape	
Fibre glass	
Thickness	

2.5 cm	0.6
5 cm	1.18

Most of the construction materials (concrete, bricks, glass blocks etc.) absorbless than 2 % of sound energy incident on their surfaces reflecting the rest 98% back to the room. Note that the level of noise produced by a source located in the room is 5 to 15% higher in loudness than that produced by the same source in open.

The application of sound absorbing materials with high coefficient of sound absorbency for walls and ceilings permit the reflected noise to be diminished thereby reducing the total noise level in workroom.

Another benefit from sound absorption is the possibility of easy aural checking on operation of machinery because a direct sound from every apparatus or a machine tool installed in the enclosure can be detected by the ear easily.

Ceilings and upper portion of walls 1.5 to 2.00 mtrs above floor levels should be lagged (insulated) with sound absorbing material.

Best result can be achieved when at least 60% of total area of walls and ceilings are insulated.

Mufflers or silencers are also one type of sound absorbers. The velocity .and pressure of the air get reduced when it is routed through devious paths in the muffler components.

The mufflers are of two types. In absorptive or dissipative type a lining of absorptive material is provided and is protected by a perforated metal cover. Reactive mufflers are similar to electrical filters and give good reduction over a narrow range of frequencies by reflecting the sound energy.

The absorptive silencer has better performance at higher frequencies whereas the reactive type at low frequencies. Sound reduction or insertion loss increases with length, thicker splitters and reduced air gap.

6.6 Sound proofing :

Soundproofing includes construction or barrier structures such as walls or partitions, to safeguard the workers from external noise.

Sound proofing utilises the principle of reflection of sound i.e. the greater part of sound energy incident on a surface is reflected and only it's smallest part (l/ 1000 or less) penetrates through it.

In fact an ideal sound proof structure should not let noise into an enclosure it safeguards. More heavy (massive) the barrier-structure, the more soundproof it is. The sound proofness of barrier surface is determined by its acoustic in entrance. It is more sound proof to high frequency sound waves than to sound waves of low frequencies. Therefore the knowledge of the characteristics of sound is very important in sound proofing. In sound proofing following factors are required to be considered for obtaining desired results of sound proofing.

1. Intensity of sound.
2. Frequency of sound.
3. Co-efficient of absorbency of material used for sound barriers.

A higher co-efficient of sound absorbency is preferred to that of low coefficient in order to get good noise attenuation.

Adequate care should be taken to ensure that all openings in the noise enclosure should be properly sealed over entire area to prevent any leakage of unwanted sound through such openings. Doors and windows should be properly fit to match the perimeter and window frames receiving glass panels should be adequately shut. All such measures should be essential for efficient isolation of room with noise producing processes.

6.7 Ear Protection :

Personal protection should be used as a last resort. Ear plugs, ear muffs and helmets can be used by the exposed person for attenuation of noise to a safe level. Where noise levels are very high, better attenuation can be obtained by using both ear plugs and ear muffs.

If properly selected and used, personal protective equipment and devices, such as sound-proof head-sets (helmets), earmuffs, earplugs and noise stoppers can afford effective protection against noise disturbances and prevent various functional disorders. To the extent that accidents and hearing loss may result from exposure to excessive noise, these devices are a preventive measure, and can be used in addition to the principal noise control, measures when they are found ineffective.

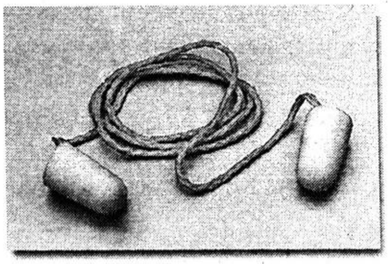


Fig. 12.10 Ear plugs

Ear plugs or defenders (Fig. 12.10) are the simplest, cheap and convenient devices used to reduce the harmful effect of noise. They are conical shaped plugs of various materials for insertion into the ear to reduce perception of noise, particularly impulse noise. They can be soft or rigid. Rigid plugs are made of rubber or plastic materials while soft plugs are of cotton cloth or of very fine glass cloth impregnated with oil or a waxy mastic. Plugs do not prevent the wearer from wearing headpieces or goggles. However, during long use, ear defenders may cause discomfort and irritation in the ear, particularly at elevated temperatures. Application of multi-use ear defenders requires special medical supervision.

Earmuffs (Fig. 12.11) are large pads of rubber or similar material attached to a band or strap and worn about the head for reducing the effect of noise on factory workers (during impact riveting, straightening, chopping and the like operations). The device is light, convenient to wear and effective against noise of high frequency which is exclusively harmful to the human ear

Fig. 12.11 Ear Protection (muff)

Head-niece or helmet is an effective device against the effect of noise levels exceeding 120 dB where the above protective devices are ineffective. High level of noise affects the skull causing the bones to vibrate. Such vibration adversely affects the auricular nerves and the brain function. Helmets provide adequate protection of the skull, particularly its paratideic region.

The systematic and correct use of ear protectors can prevent hearing loss and other noise induced health impairment.

The efficiency of ear protectors is expressed by the degree of attenuation of the noise penetrating into the external ear canal. Noise attenuation by ear protectors is limited by bone conduction for high frequencies and by skin resistance to low ones. Earmuffs offer higher attenuation than earplugs at the same frequency. Hearing protector's attenuation capacity is known as Noise Reduction Rating (NRR) and must be printed on the package.

Hearing protective devices are classified in four groups:

1. Enclosures (entire head) e.g. helmet.
2. Aural inserts e.g. earplugs - formable, custommoulded & remoulded type.
3. Super aural protectors - A soft rubber like material is held and inserted in the external ear canal. Band tension holds it inside (ear plugs).
4. Circum aural protectors e.g. earmuffs. Two cups are held by a spring-loaded suspension assembly or headband.

See Part 5.2 of Chapter-25 on PPE.

6.8 Rotation of personnel :

Since the effects of noise on hearing depend partly on the length of exposure, the bad effects may be reduced by removing the worker from the noisy environment wherever audiograms indicate a hearing loss.

See also administrative controls mentioned in Part 6.10. There rotation of noisy job or worker or dividing the noise period among one or more workers to reduce their exposure time are explained. Rotation of personnel or changing their work place should be done by taking their union in confidence so as to avoid any labour problem. As this is for the purpose of safety and health, normally they should co-operate.

6.9 Active Control (Antiphase) System:

Sound waves are intervened and obstructed by similar powerful sound waves to nullify their effect. Thus 'sound against sound' is the principle employed here. Reference microphone, error sensor and active control unit are used. Reference microphone detects the sound coming from source and supplies information to controller unit. This control unit with the aid of digital signal processing system, calculates the drive signals. Loudspeakers use these drive signals to give antiphase sound. Upper and bottom peaks of sound waves (cycles) are flattened. Bottom curves of drive (control) sound waves are thrown on the top curves of the sound waves to be absorbed. This modern system is useful to control noise from diesel engine, gas turbine, aeroplane, submarine and compressors.

6.10 Other control methods:

Most of the practical aspects to control noise at source are given in foregoing Part 6.1 to 6.9. Some other control methods are as under :

1. Substitution of non percussion tools and processes for pressure ones e.g. use of hydraulic drives instead of cam or eccentric drives and straightening instead of forged rolling etc.
2. Use of rotational, preferably uniform motion instead of reciprocating motions,
3. Use of vee-belt transmission instead of chain or gear transmission,
4. Use of lubricant baths for meshed gears and forced feed lubrication for articulated joints to minimise wear and noise caused by friction.
5. Use of lining and elastic inserts in joints to avoid or mininlise transfer of vibrations from one part to another.

6. Use of rubber lining for insides of metal containers and crates to be used for material handling.
7. Use of plastic and mute materials for metal or combination of metal parts with plastic.
8. Keeping fans and engines off when not in use.
9. Good regular maintenance by tightening loose guards and panels.
10. Oiling, greasing and replacement or adjustment of worn, loose or unbalanced parts of machines.
11. Reduction of forces and speeds.
12. Use of vibration dampers.
13. Reduction in radiating area and overall size.
14. Use of flexible mountings and couplings.
15. Use of resilient flooring and sound absorptive material on walls and ceiling.
16. Reduction in pressure, turbulence and increase in the cross section of the streams.
17. Elimination of air and steam leaks.
18. Increase in the distance from the noise source.

Care at the planning stage is more useful. Vendors and suppliers should be asked to provide information on the noise levels of currently available equipment. The inclusion of noise specifications in purchase orders is useful to get quiet equipment. If purchasers will insist, the designers will pay more attention on noise control.

Remote control of noisy equipment or its isolation in a separate room can control the exposure.

Administrative controls such as providing ear protection to workers, rotation of Jobs or workers in order to reduce their exposure times, transferring workers from high noise location to lower one for some period, scheduling of machine operating time so as to reduce the radiating time and also the number of workers exposed to noise, transferring more susceptible workers to less noisy area or dividing work at high noise level or extended period among two or more workers, if it may not cause any personnel problems.

Implementation of the legal standards and purchase agreements is also essential to reduce noise levels in all work places.

Despite of all efforts, periodical audiometric tests of workers working in high noise areas must be carried out and their records maintained.

7 AUDIOMETRY

In industrial situations pure tone audiometry for air conduction is carried out. An audiogram taken during the pre-placement medical examination serves as a reference level. Repeat audiograms can be taken at suitable intervals, depending upon the exposure to noise and the susceptibility of the person. Audiometry is useful in detection of hearing impairment at an early stage, evaluation of the ear defenders and evaluation of other control measures.

Zero dB is the reference level on the audiometer set as per 'standard' of the celebration. It indicates normal threshold hearing level of a healthy adult person as average of many tests. Now on test, if a person indicates 40 dB hearing threshold at 4000 Hz, 40 dB is a "hearing loss' or hearing, deficiency or 'hearing level' on that audiometer.

The audiogram serves to record the results of the hearing tests.

An audiogram: An audiogram (Fig 12.12) is a measure over a range of frequencies, of the threshold of hearing at which sound can Just be detected. Early deafness occurs in the frequency range of 2-6 KHz and is shown typically as a dip in the audiogram at 4 KHz. The depth of dip depends on degree of hearing damage and as this damage worsens, the loss of hearing widens to include neighbouring frequencies.

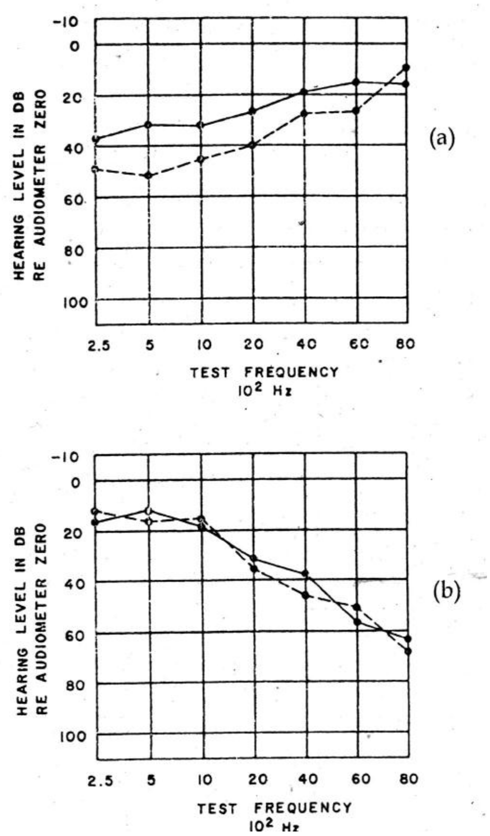

Fig 12.12 : Audiograms showing hearing loss of type (a) conductive and (b) Sensorineural

The advantages of an audiogram 'are that

1. It provides a baseline for future comparison.
2. It is helpful in job placement.
3. It can be used to detect early changes in hearing and in the diagnosis of noise induced hearing loss (deafness).

Audiometric Tests: Audiometric tests measure a person's threshold of hearing at selected sound frequencies. The test instrument is called an Audiometer and record obtained is called an "Audiogram".

The audiometer presents a variable sound pressure level in an earphone and measures at selected frequencies the minimum audible sound pressure level (threshold) that the person can bear and compare it with die average threshold of hearing of young person with no hearing impairment. The difference in decibels between the two thresholds is reported as hearing loss at each frequency and for each ear.

All employees are expected to show some hearing loss because there is a natural loss in hearing as we grow old.

Hearing tests or Audiometric tests are key to protecting all employees. It helps to identify those employees who are highly susceptible to noise induced hearing loss. So these individual can be given better protection long before their loss becomes permanent.

Audiometric tests are conducted on employees who work in high risk areas.

Benefits of Audiometric Tests are as under:

1. Pre-employment test helps employer to identify those employees who have developed hearing damage on account of prior job.
2. Periodic tests of employees exposed to low risk areas help detecting those employees who have developed hearing loss on account of off the job activities or medical disorders.
3. A baseline audiogram indicates individual's hearing ability at the time of the pre-placement examination. This can be compared with future tests results.
4. Provide a record of an employee's hearing acuity.
5. Check the effectiveness of noise control measures by measuring the hearing thresholds of exposed employees.
6. Record significant hearing threshold shifts in exposed employees during the course of their employment.
7. Help to decide about Hearing Conservation Programme.
8. Suggest need of appropriate ear protector or to suspend the employee from noisy atmosphere.
9. Compliance with government regulations.

An effective industrial audiometric program includes following components:

1. Medical Surveillance.
2. Qualified personnel.
3. Suitable test environment.
4. Calibrated equipment, and
5. Adequate records.

First engineering controls should be employed. Then ear protectors should be given. Even then the sound level is not within limit, period of exposure should be reduced as given in Table-12.5 or the workers should be transferred to less noisy area and audiometric tests should be carried out.

8 HEARING CONSERVATION PROGRAMMES

This requires two things (1) Noise surveys and (2) Audiometric tests of workers.

8.1 Noise Surveys:

Two types of noise surveys are carried out, preliminary and detailed. A hearing conservation program starts with a preliminary noise level survey where workers are exposed to high noise levels.

A noise survey becomes necessary where it is difficult to communicate in normal tones or where speech and other sounds are muffed for several hours or where workers develop ringing in their ears.

From the preliminary noise survey it becomes easy to determine where more detailed surveys are necessary. A detailed noise study should then be carried out at each such location to determine workers' TWA exposure.

Three steps are necessary for noise survey procedure

1. Area measurements.
2. Workstation measurements (to evaluate the noise exposure between 80 to 92 dBA).
3. Exposure duration.

8.2 Noise Conservation Programme:

Because of wide variations in human response to noise, it is unrealistic to set a limit which protects the vast majority of employees. Hearing conservation programmes are designed to ensure that all employees are protected.

A comprehensive hearing conservation programme calls for following:

1. Plant noise surveys to monitor noise exposure levels. Noise measurement, analysis and reduction by engineering controls.
2. Pre-employmentand periodic audiometric tests, record and audiograms and their evaluation.
3. Hearing protectors to workers exposed to 85 dBA or more.
4. Record keeping of workplace and noise exposure measurements.
5. Training to workers regarding such programmes.

Hearing tests, usually called audiometric tests, are the key to protecting all employees. Audiologists use them to identify employees who are highly susceptible to noise-induced hearing loss, so these individuals can be given better protection long before their loss becomes permanent. Audiometric tests are usually conducted at 6 monthly intervals on employees who work in high risk areas.

Hearing tests also provide other benefits. Pre-employment tests protect employers from assuming responsibility for hearing damage incurred on a prior job. Periodic tests, normally once a year, on employees exposed to low-risk environments can detect hearing loss due to off-the-job activities or to medical disorders.

An effective hearing conservation programme should be undertaken where exposure to industrial noise is capable of producing hearing loss. The object is to ensure that an employee's hearing is not affected during his working life to an extent greater than that usually occurring with age and to preserve it at a level sufficient for normal speech reception. Conservation programme is needed in situations where the hearing loss, as measured by audiometry, is more than 10 dB at 4000 Hz. It is also indicated when the sound level in the working environment is more than 90 dB and there is difficulty to communicate by speech.

9 WORKED EXAMPLES

Characteristics of sound waves

As sound energy is transmitted through a medium in waves, it exhibits certain properties. (1) The longitudinal waves travel at a velocity or speed. The speed of sound differs depending upon the medium of temperature and pressure in which it is traveling. At 0° C and one atmosphere of air pressure, the speed of sound is accepted as 331.3 ml/sec. As the temperature (T) increases, the speed of sound also increases at approximately 0.60 mt/sec for each 1° C.

Example-1 : What would be the speed of sound(s) at 20° C and 1 atmosphere?

$$\begin{aligned} S &= (331 + 0.6T) \text{ mt/sec} \\ &= (331 + 0.6(20)) \\ &= (331 + 12) \end{aligned}$$

= 343mt/sec .

Calculation of Sound Pressure Level

Lp = 20 log p/po Where, Lp = the sound pressure level, p= rms sound pressure, po= a reference sound pressure and log= logarithms to the base 10. The sound pressure level or Lp in a very quiet room, where the sound pressure is 0.002 Pa, is calculated: Lp= 20 log (O.OC2/ 0.00002) = 20 log (100) = 20 X 2 - 40 dB

Example-2 : Calculate sound pressure level of a typical gasoline-powered lawn cutter, which has a sound pressure of I Pa.

Sound pressure Level Lp = 20 log (1/0.00002) = 20 log (50 000) = 20 X 4.7 = 94 dB

Calculation of Sound Power Level

Sound power levels or Lw are determined by the following formula:

Lw == 10 log (Sound Power Level / Reference Power Level)

The reference power is one trillionth of a watt (0.000000000001 W). Therefore

Lw = 10 log (Sound Power Level / 0.000000000001)

Thus, the sound power level associated with an average whisper, which has asound power of 0.0000001 W, is calculated as

Lw = 10 log (0.0000001/ 0.000000000001) = 50 dB

Amplitude:

1. The amplitude of sound can be measured as an - intensity level (IL); although more commonly as the sound pressure level (SPL).
2. For an ideal point source in a free field (where the source is in open air or where reflection is limited) the intensity of sound radiated is given in following equation

1 = W/45 ϖ r2

Where: ‘I' is intensity of radiated sound

'W' is power (Watts)

'r' is the distance from the source (m)
Example of this type of noise may be a small loud speaker operating at low frequency.

Calculation (computation) of Noise Exposure

(1) For general classes of noise exposure -

When the sound level ,L is constant over the entire work shift, the noise dose, D in percent, is given by : D= IOOC/T

Where, C is the total length of the work day, in hours and T is the reference duration corresponding to the measured sound level (available from table or following formula) = 8/2(L-90)/5

Where, L is the measured A-weighted sound level, 90 is the criterian sound pressure level as per Factories Act.

(2) When the daily noise exposure is composed of two 'or more periods of noise exposure of different levels, their combined effect should be considered, rather than the individual effect of each. If the sum of the following fractions :

C1/TI + C2/T2......... Cn/Tn exceeds 100 percent, then the mixed exposure should be considered to exceed the limit value. Cn indicates the total time of exposure at a specified noise level, and Tn indicates the total time of exposure permitted at that level.

(3) When employees are exposed to different noise levels during the day, the mixed exposure (Em) must be calculated by using the following formula:

Em= CI/TI •+ C2/T2 + C3/T3+ ...... Cn/Tn In this formula -

Cn - equals the amount of time an employee was exposed to noise at a specific level

Tn - equals the amount of time the employee may be permitted to be exposed to that level.

If the sum of the fractions equal or exceed 1, then, "the mixed exposure is considered to exceed the limit value.' Daily noise dose (D) is an expression of Em in percentage, eg. Em = I, is equivalent to a noise dose of 100 percent. Noise levels below 90 dBA are not considered in the calculation of daily noise dose.

Example-3 : A drill operator in underground mine is exposed to the following noise levels during the workday. Calculate the daily noise dose to him.

95 dBA for 2 hours, 90 dBA for 2 hours, 115 dBA for 0.25 hours

Thus, the daily noise dose is as follows:

D = 100 [2/4 + 2/8 + 0.25/0.25)
= 100(1.75)= 175%

Since the dose exceeds 100 percent, the employee received an excessive exposure during 1~ workday.

(4) The eight hour time weighted average sound level (TWA), in decibels, may be computed from the dose, in percent, by means of formula

TWA = 16.61 log10 (D/100) + 90

Where, TWA = 8-hour time weighted average sound
Level and D = Accumulated dose in percent exposure

Part B : VIBRATION

10 GENERATION, NATURE & TYPES OF VIBRATION

Vibration is a physical factor which acts on human body by transmission of mechanical energy from sources of oscillation.

Sources of oscillation may be knocks and friction of machine parts, unbalanced or inaccurately centred rotating parts, pressure pulses of compressed fluid etc.

Sources of vibration include

1. Rotation with unbalanced loads or bent shafts.
2. Misalignment of driving and driven parts.
3. Impact of a moving part against another part moving or stationary.
4. Water hammer in hydraulic systems.
5. High velocity air in ducts.
6. Looseness of equipment parts which causes them to rattle like shieving.
7. Lack of adequate snubbing devices in pneumatically operated equipment.
8. Flat spots or bend on bearings or steel wheels.
9. Worn or separated treads or nails or other objects embedded in tires.
10. Belt or gear slippage.

Vibration transmits more 'easily through solid materials than through air.

Frequency, amplitude and duration are the characteristics (nature) of vibration. Like noise, frequency is measured in cycles per second or Hertz. Frequency dial coincides with the body's own resonance tends to be the most uncomfortable; this being in the range of 2-30 Hz. Amplitude is the acceleration given by meters per second per second (rn/s^2) and denotes how far the surface moves each time it vibrates. Duration is the period how long it goes on. The longer is the exposure, the higher the risk.

11. EFFECTS OF VIBRATION

Types of vibrations are Whole Body Vibration (WBV) or Segmental or Hand Arm Vibration (HAV). Vibration of the whole body due to supporting structure (e.g. vehicle seat or a building floor) is of the former type while vibration of any body part (e.g. -hand or foot due to a vibrating tool) is of the later type.

Effects on Human Body : Effect on human body is due to frequency, amplitude and duration of exposure.

Vibration can cause annoyance and noise to human body and physical damage to machines and structures. Vibration can harm only if some part of the body is in direct contact with a vibrating surface viz. the seat of a vehicle or the handle of a power tool.

Effects of vibration are feeling of disoriented or displacement, giddiness, sickness, vibration disease and sometimes fatal. Whole body vibration can cause permanent damage to body or abdominal, spinal and bone damage. Vibration-induced White Finger (VWF) known as dead hand or Raynaud's Phenomena is a damage to the blood vessels and nerves in fingers due to a long use of vibrating power tools such as chipping hammers, chisels and drills.

Hand-arm vibration syndrome (HAVS) cannot be controlled by working within TLV only. Other control measures like use of anti vibration tools and gloves, proper work practices and medical surveillance program are also necessary.

TLV of vibration (HAV or WBV), as given by ACGIH Booklet (2007) is as under -

Total daily exposure time to vibration	Component acceleration which should not be exceeded	
	m/s^2	G
4 to less than 8 hrs	4	0.40
2 to less than 4 hrs	6	0.61
1 to less than 2 hrs	8	0.81
Less than 1 hr	12	1.22

$g = 9.81\ m/s^2$.

Human vibration resonance occurs in 4 to 8 Hz frequency range for Z-axis (vertical axis passing through human legs and head) and in I to 2 Hz frequency range for -X axis (across chest) and Y axis (across shoulders).

It causes numbness and blanking of the fingers with probable loss of muscular control and reduction of sensitivity to heat, cold and pain. It causes paleness of the skin due to oxygen deficiency. All vibrations make us tired or irritable.

Low frequency vibration (3-6 Hz) can cause diaphragm in the chest region to vibrate giving feeling of nausea. This resonance effect can be felt near large slow speed diesel engines and occasionally ventilation systems.

In 20-30 Hz frequency region, resonance effect on head, neck and shoulders, in 60-90 Hz, effect on eyeball and in 100-200 Hz effect on lower jaw and skull subsystem are reported. Normal ill-effects are possible in the range of 3-400 Hz.

The vibration causes the blood vessels to contract and restrict die blood supply, to the fingers creating an effect similar to the fingers being cold.

Localised vibratory effects may cause

1. Changes in bone - Decalcification in carpal bones which can be seen on x-ray.
2. Development of muscular weakness and degenerating alternatives in uluar and median nerves.
3. Muscular changes and muscle atrophy.
4. Ieuosynonities.
5. Dupuytreu's disease and
6. Cysts on some of the bones of the hand.

Initial treatment should be the rest and transfer to other work. .

Whole body vibration may cause

1. Increase in oxygen consumption.
2. Increase in pulmonary ventilation and cardiac output. Affects CNS, damages internal organs.
3. Difficulty in maintaining steady posture.
4. Effects on visual acuity and narrows the field of vision.
5. Marked changes in bone structure

- Spondylities.
- Deformations.
- Intervertebral Osteochondrosis.
- Calcification of the intervertebral disc.
- Schmorl's nodes.

6. Blood changes -
   - hypoglycaemia.
   - hypocholesteremia.
   - low ascorbic acid levels.

7. Alternations in the electrical activity of the brain.
8. Effects on endocrine, biochemical and histopathologic systems of the body.

As per ACGIH pocket book-2000, low frequency sounds -50 to 60 Hz (chest resonance range) - can cause whole body vibration, annoyance and discomfort. The SPL (sound .ptessure level) of such sound should be reduced to a level where the problem disappears.

Segmental vibration is a localised stressor creating injury to the fingers and hands of exposed workers using such vibratory hand tools as chain saws, pneumatic chopping hammers and picks and electrically operated rotary grinders.

Vibration may affect comfort, reduce work output and cause disorders of physiological functions giving rise to the disease in case of intense exposure.

At low frequencies (up to 10 Hz) the vibrations propagate through the entire body regardless of the location of input. In case of high frequency vibration, the zone of propagation is limited by the area of contact causing vascular disorders in that part.

Effects on Machines & Structure: Badly vibrating machines not only consume more power but also damage to the machine and its supporting structure. The vibrations also travel through the structure of the building and be radiated as noise at distant points. This is structure - borne noise.

Vibration causes metal fatigue which results in failures of rotating parts and other stressed mechanical equipment. It can cause rupture in a pressurised equipment, the higher the pressure, more chances a rupture.

See Part 4.1 of Chapter-17 also.

12 VIBRATING EQUIPMENT AND MEASUREMENT

Vibrating equipment include pneumatic, electric and petrol powered tools, pneumatic road breakers hammers, chisels and their variants, rotary rock drills air tools, rotary/percussive electric drills, riveting hammers, electric grinders, polishers, circular saws and petrol-powered chainsaw. Weaving looms, concrete mixtures (vibrators), tractors, threshers, some self propelled equipment, demolishing hammers, concrete breakers and nut runners also cause vibrations.

Czech limits for vibration are given in rms acceleration (m/ 2) for 8-hr exposure. Oscillator) velocity safe limits are also used.

13 CONTROL MEATHODS

Sound control methods described in parts 6.1 t(6.7 can also be useful to control vibration if properly applied.

Fig. 12.13 Vibration Monitor

Vibration monitors are available as shown in fig12.13 to measure level of vibration. They should be utilized for the selection of proper vibrating tool or equipment.

Main control measures are as under :

1. Vibration Isolators can effectively reduce transmission of vibration waves when properly install. This is isolation at source.
2. Reduction of Surface Response (Damping)' When isolation at source is not possible, vibration absorbers (Dampers) can be effectively used.
3. Reduction of Mechanical Disturbance that produce vibration. This is possible by reducing impects, sliding or rolling friction or unballance.

13.1 Vibration Damping:

Vibration dampers (absorbers) are used under machine foundation and the machine should be installed on an inertia block with a damping sandwich between it and the building foundation. But before this provision, efforts should be made to balance the moving parts of the machine which is the better remedy.

The method chosen should depend, on the size and weight of the machine, the frequency of the vibration to be controlled and the degree of isolation required.

13.2 Other Methods :

Vibration control measures include technical, organisational, hygienic, prophylactic and therapeutic measures.

(1) **Technical or engineering measures** include automation, remote control and eliminating or reducing vibration from the design stage or at source, use of vibration dampers, device for prevention, suppression, damping and insulation of harmful vibrations, use of automatic devices to avoid contact with the vibrating body, changes in the design parameters of machines, equipment and mechanised tools, static and dynamic balancing, selection of inertial and elastic parameters that avoid operation in regions of resonance, gyroscope installations to damp angular vibrations, active vibration (automatic suppression of vibration), 'acoustic . gaps' or movement arresters filled with a porous material, and a functional joint at the base-plate, elastic (deformable) inserts, vibration pads (supports), anti-vibration bushings, reduction in weight of hand-held machines etc.

(2) **Organisation measures** include good preventive and corrective maintenance and arrangement of work schedules in such a way to decrease time of exposure.

(3) **Prophylactic and therapeutic measures** – pre-employment and periodical medical examinations play an important role. Special gymnastics, hydrotherapeutic procedures, massage and UV radiation can prevent further development of vibration disease and preserve working capacity.

(4) **Special vibration absorbing handles** fitted to hand tools, springs, suspension seats and shock absorbers are useful.

(5) **Reduction in exposure time.** Rotate vibrative job and introduce rest schedules so that individual exposure is shortened.

(6) **Personal precautions** include watching for symptoms, to apply loose grip, to wear gloves and footwear with shock-absorbing soles to damp vibration to use PPE and to get medical attention.

(7) **Automation and remote** control system.

14 INDIAN STANDARDS

Some IS on Vibration are : Vibration and shock, vocabulary 11717, isolators 14259, vibrating feeder, mechanical 12401, vibrating screens - 12213, supplier's data sheet 8580, vibrating tables, concrete 2514, use 7246, vibration galvanometers 7889, measurement of human exposure 5349, whole body vibration 13276, 13281, vibration machine 10080, mechanical balancing 14280, measurement on rotating shaft 7919, vibration severity, measurement 11727, test optical instrument 10236, vibration dampers for overhead power lines 9708, vibrator pan 3366, purchaser's data sheet 8660, vibrator plate compactor 5889, vibrator roller 5500, 11391.

From above, IS 11717, 14259, 7889, 5349, 11727 and 10236 have general applicability and should be referred for details.

E X E R C I S E

1. Explain, State, Mention or Discuss :

1. What is sound and how is it perceived ?
2. What are the characteristics of sound?
3. What do you mean by 'loudness'? Does it depend on what? Give three examples of its levels in different industries.
4. Study reports showing the effects of noise on productivity.
5. What are auditory and non-auditory ill effects of noise?
6. Noise induced hearing loss and methods to measure it.
7. The results of a study of psychological effects of noise on steel workers.
8. What are the sources of industrial noise? Explain with examples.
9. Different methods of measurement of noise. What could ~be the objects of such measurement?
10. If you have to design a sound measurement report, what will be the contents?
11. What do you mean by recognition evaluation and control of noise hazards? Explain the steps and difference between them.
12. Factors affecting degree and extent of hearing loss.
13. What are the types and steps for noise surveys?
14. Various control measures for noise.
15. Different methods of noise control.
16. What do you mean by ear protection ? Explain the types of such protectors.
17. What is audiometry and audiogram? What does an effective audiometric program include?
18. The nature and types of vibration. The effects of whole body vibration. OR Segmental vibration (local effects) Different types of vibration control methods.

2. **Write Short Notes on :**

1. Nature of sound OR Generation of sound.
2. Types of sound OR Mode of sound propagation.
3. Types of hazards due to excessive noise.
4. Factors affecting effects of noise.
5. Damage Risk Criteria due to noise.
6. Meaning and types of 'hearing loss'.
7. Signs and symptoms of hearing loss.
8. Auditory fatigue OR Temporary Threshold Shift (TSS)
9. Masking as sound effect OR Noise control at source.
10. Effects of noise on human body.
11. Need or usefulness of measurement of noise.
12. Risk areas of noise measurement.
13. Noise dose and noise dose meters.
14. TLVs for noise OR TLVs for vibration.
15. Method to measure TLV for noise.
16. A noise dosimeter OR A sound level meter.
17. Types of sound measurement.
18. Noise (hearing) conservation program OR Meaning of dBA.
19. Statutory provisions for noise induced hearing loss.
20. Noise levels in public areas.
21. Noise exposure limits for continuous noise and impulsive or impact noise.
22. Sound absorption method OR Sound proofing.
23. Administrative control methods for noise OR Noise isolation.
24. Types of hearing protective devices and merits and demerits of them.
25. Antiphase noise control system.
26. Requirements of comprehensive hearing conservation program.
27. Benefits of hearing tests. OR Test cycle for hearing loss.
28. Effects of vibration on human body.
29. Sources of vibration.
30. Vibration damping OR Hand arm vibration syndrome (HAVS)

CHAPTER – 13

Fire and Explosion

THEME

1. FIRE PHENOMENA :

Fire is the oldest phenomena. People have seen fire since their existance. Controlled fire is a friend of mankind and is useful in many ways. It is an uncontrolled fire for which fire safety is required.

1.1 Nature of Fire :

Fire is an igneous element Whose potentiality is well recognised in our Indian culture. Like izdk'k (light), ok;q (wind) and ty (water), vfXu (fire) is our God and we worship them to protect us. They are the supreme elements and without them the human life is not possible. Olquka ikod'pkfe and vgefXu is said by Lord Krushna in Gita meaning thereby that he is vfXu amongst eight Vasus. ;K is the divine form of vfXu and through ;K we achieve everything.

The destructive nature of fire and need of protection is also explained as follows:

_.k'ks"k'pkfXu'ks"k% 'k=q'ks"kLrFkSo p A
iqu% iqu% izo/kZUrs rLekr~ 'ks"ka u 'ks"k;sr~ AA

Remainder of debt. fire and enemy grows again and again, therefore, they should be ended, not leaving any remainder. It is any remainder. It is explained earlier that u dwi[kuua~ ;qDra iznhIrs ofguuk x`gs i.e. it is of no use (too .late) to dig well when it is already fired in the home. Tims prevention is better than care and it is truer in case of fire prevention.

1.2 Need of Fire Safety :

Main object of fire safety is to protect life first and property next from the ravages of fire. Objectives of fire safety design are safety of life, protection of property and continuity of operations. Fire safety planning is required for sites as well as buildings. In industry, it is required for workers and public.

Potentiality of fire is tremendous as it holds the largest range of damaging capacity from a small burn to the disastrous damage of plants, persons and properties. Some glorying examples of fire and explosion are given in Table 13.1.

Table 13.1 Examples of Major Fire & Explosion.

Year	Plant & Place	Death	Serious Injuries
1942	Coal dust explosion, China	1572	-
1944	Ship explosion, Bombay	231	476
1947	Ship fire / explosion, Texas, USA	576	2000
1956	Truck explosion, Columbia	1100	-
1975	Mine explosion, Chasnala, India	431	-
1984	Petrol line fire, Brazil	500	-
1984	LPC fire, Mexico	500	7000
1993	Fire in a toy factory, Thailand	211	-
1994	Huge fire in oil refinery, Cairo, Egypt	132	-
1994	Fire in a dance hall, Beijing, China	233	16
1995	Fire in a moving train, Moscow, Russia	375	-
1995	Fire due to short circuit, Sirsa, Hariyana	368	-
1995	A leaking gas pipeline exploded, Taegu, South Korea	109	160
1997	Gas fire in pilgrims, tents, Mecca, Saudi Arabia	343	-
1997	Fire following explosion in a refinery, Vishakhapatnam, AP	60	-
1997	Fire while mopping up petrol spillage from a burst pipeline in Southern Nigeria, Egypt	500	-
1999	Gas explosion in a coal mine, Beijing, China	35	8
2000	Fire at Christmas party (discotheque) in lqoyang city in China on 26-12-2000.	309	-

Courtesy : LP News.

See also Table 13.9 for Explosion events.

Similarly some examples of estimated fire loss inferred from the fire insurance claims are given in Table 13.2.

Table 13.2 Examples of fire loss

Date	Place	Loss in Crore of Rs.
5-6-82	Calico Mills, Baroda	15.01
3-6-94	Parasrampuria Synthetics	13.32
5-12-94	Tata chemicals	10.00
18-11-95	Madras Refineries	51.60
14-12-95	Vikram Ispat	62.00
18-11-96	Fire on goods, train in Tunnel, France	366 USD
14-9-97	Fire at HPCL refinery, Vizag, AP	50

Courtesy: LP News.

These roaring figures of heavy losses of men and money strengthen the permanent need of fire safety. In industry, we store and use many materials which are capable of giving or catching fire. Many processes, equipment and situations create fire hazards. All these need proper detection and measures of fire prevention and control. This is in the interest of all.

1.3 Chemistry and Pyramid of Fire :

1.3.1 Triangle of fire.

According to old concept, three elements are necessary to start fire. They are (1) Fuel (2) Oxygen arid (3) Heat or Source of ignition. Fire is not possible if any one of these elements is not available. This is shown in figure 13.1.

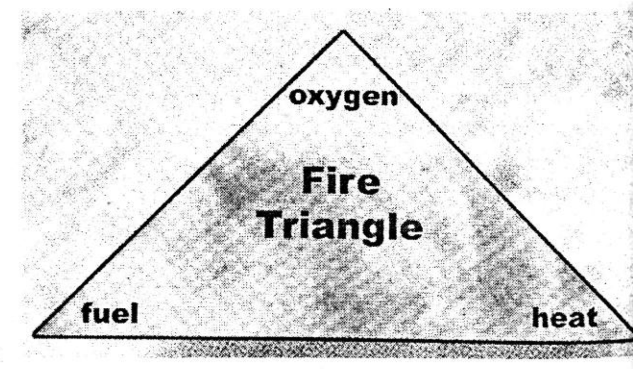

Fig 13.1 : Triangle of Fire.

1.3.2 Pyramid of Fire.

According to this concept, four elements are' necessary to start fire. They are as under

1. Fuel (combustible material and reducing agent).
2. Oxygen or oxidant or oxidiser (from the atmosphere).
3. Heat or source of ignition (necessary to start the fire initially, but maintained by the fire itself once it has started and
4. Chain reaction through free radicals to maintain the fire.

This is shown in fig. 13.2

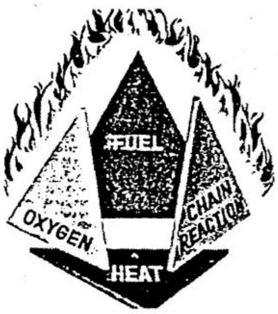

Fig. 13-2 : Pyramid of fire.

If any one of above four elements is removed, the fire goes out. Therefore methods of fire extinguishment are dependent on:

1. Removing or shutting off the source of fuel.
2. Excluding oxygen or decreasing it below 14 to 18% by adding inert gases.
3. Removing heat from the fire faster than its liberation and
4. Removing free radicals to discontinue chain reaction and flame propagation. Dry powder chemicals and halogenated hydrocarbons capture free radicals and put out fire in this way.

Thus fire is a rapid chemical oxidation reduction reaction. Oxygen in air acts as an oxidiser and fuel acts as a reducing agent and burning material. It is an oxidation of a substance (which burns ie fuel) accompanied by heat, light and flame. Due to incomplete combustion it evolves smoke and carbon monoxide which creates invisibility and toxic atmosphere for fire fighters.

An excess of air can cool the combustion gases to quench the fire, if the combustible material is small, otherwise it cannot, as in case of forest fire where the combustible material is too much to cool.

The chemical reaction is exothermic as it evolves heat and the heat released is used for the reaction to continue.

Fire is a burning or combustion phenomena and the combustion may be kinetic or diffusive depending upon homogenous or inhomogeneous air-fuel mixtures. The combustion may be complete or incomplete. The complete combustion gives product like CO_2, SO_2, water vapour etc., which cannot burn any more. The incomplete combustion (due to insufficient or blocked air) gives CO, alcohol, aldehydes etc., which can burn further more.

The amount of air required to burn 1 kg. of combustible material (or 1 m^3 of gas) is roughly given by $V = 1.12\ Q/1000$, where Q is the heat of combustion kJ/Kg. or kJ/m^3. Rate of burning also depends on the status of fuel i.e. solid, liquid or gas.

1.4 Stages of Fire :

Mostly fire develops in four stages as under

1. Incipient stage - No visible smoke, flame or more heat developed. Invisible combustion particles are generated over a period of minutes, hours or days. Ionisation detectors respond to these particles.
2. Smouldering stage - Visible smoke generation. Photoelectric detectors can detect this smoke.
3. Flame stage - Flame starts after point of ignition. Smoke decreases and heat increases. Infrared detectors can detect this stage.

4. Heat stage - Heat, flame, smoke and gases are produced in large amount. Thermal detectors respond to this stage.

See Part 5.2 for such types of detectors and alarms.

1.5 Spread of Fire :

It depends on the following factors :

1. The area of the substance exposed;
2. TT-ie amount of heat generated or given off by the burning substance;
3. The ability of the substance to conduct the heat away from the zone of combustion;
4. The atmospheric humidity and the wind velocity.

Thus fire will spread more if more combustible area is available, if more heat is: given by the burning material, if more heat conduction is possible and if atmospheric humidity is less and wind speed is high.

It is important to prevent or reduce the spread of fire. Following factors are useful in this regard.

1.6 Definitions :

To understand fire and explosion phenomena and their related subjects, following definitions are useful.

1. Auto-ignition (spontaneous ignition) temperature is the temperature at which a material will self-ig0nite and sustain combustion in the absence of a spark or flame.
2. Automatic Fire Alarm System is a fire alarm system comprising components and sub system required for detecting a fire, initiating an automatic alarm for fire and initiating other action as required.
3. Combustibility (Flammability or Ignitability) is the capacity of a substance to ignite and continue to burn in the presence of a heat source.
4. Combustion or fire is a chemical change (reaction) accompanied by the evolution of heat and light.
5. Control Centre is a permanently manned room preferably on ground floor within the premises at risk for the receipt of emergency calls and equipped with communications needed for transmission of calls for assistance to services, such as fire and police.
6. Detonation is propagation of flames following shock wave through pipes, vessels, etc., at a very high speed (supersonic) and high localised pressure.
7. Explosion is an extremely rapid chemical (explosive) transformation of fuel accompanied by release of energy and compression of gases capable of producing mechanical work.
8. Extinguishing media are agents which can put out fires. Common extinguishing agents are water, carbon dioxide, dry chemical, alcohol foam, halogenated gases (Halons) and water jel compound.
9. Fire or combustion is a rapid oxidationreduction reaction which results in the production of heat and generally visible light. A substance combines with an oxidant and releases energy. Part of the energy released is used to sustain the reaction.
10. Fire Alarm System is a combination of components for giving an audible and visible and/or other perceptible alarm of fire. The system may also initiate other ancillary action. It includes manual call points for initiating alarm.

11. Fire Point is the lowest temperature at which a mixture of vapour and air continues to burn when ignited.

12. Fire Resistance is the ability of an element of building construction, component for structure to fulfil, for a stated period of time, the required stability, fire integrity and/or thermal insulation and/or other expected duty in a standard fire resistance test (see IS 3809).

13. Fire Resisting Wall is a wall capable of specifying -the criteria of fire resistance with respect to collapse, penetration and excessive temperature rise.

14. Flammability limits (Explosive range) i.e. the values (upper and lower) expressed in percent by volume of fuel vapour in air, is the range of concentration within which a particular vapour or gas mixture with air will burn (or explode) when ignited. Below me LEL the mixture is too lean to burn and above the UEL it is too rich to burn.

15. Flameproof Enclosure is an enclosure for electrical machinery or apparatus that will withstand, when the covers or other access doors are properly secured, an internal explosion of the flammable gas or vapour which may enter or which may originate inside the enclosure, without suffering damage and without communicating the internal flammation (or explosion) to the external flammable gas or vapour in which it is designed to be used ' through any joints or other structural openings in the enclosure. (The term 'explosion proof is synonymous).

16. Flash back occurs when a trail of flammable gas, vapour or aerosol is ignited by a distant spark, flame or other source of ignition. The flame then travels back along the trail of fuel to its source resulting into fire or explosion.

17. Flash fire is vary rapid combustion.

18. Flash Point is the lowest temperature at which a liquid will give off enough flammable vapour at or near its surface, such that its mixture with air' can be ignited by a spark or flame. It is of more interest in safety than the fire point.

19. Fuel is a substance that acts as a reducing agent, giving up electrons to an oxidiser (e.g. Oxygen in air) in a chemical combustion. It may be an element like carbon, hydrogen, magnesium etc., a single compound like CO, methane CH,, a complex compound like wood or rubber or. mixture like LPG.

20. Ignition of a flammable mixture takes place when it comes in contact with a source of ignition with sufficient energy or the gas reaches an auto ignition temperature and self (auto) ignites.

21. Ignition Temperature is the lowest temperature at which ignition occurs in a mixture of explosive gas and air when the method specified in IS 7820 is followed. (Flash point is a higher temperature at which the most explosive mixture will ignite spontaneously on account of the environmental temperature).

22. Material Factor of a substance is a measure of its energy potential and is a function oi flammability and reactivity of the substance. The flammability depends upon the flash point or heat of combustion while the reactivity depends upon the instability of water. Higher is the Material Factor, higher is the fire and explosion hazard potential of a particular substance. For details see NFPA-704-M-1969.

23. Smoke Vents are openings, fitted with manual shutters for removal of smoke from a fire.

24. Spontaneous Ignition or Combustion occurs as the result of the gradual development of heat generation by chemical changes. For example, baggas (grass) cubes heaped to be used as fuel, generate sometimes, spontaneous combustion without spark and resulting into fire. Similarly oil soaked rags can sometimes ignite without spark due to combining with oxygen (oxidation), evolving heat and if the heat given off reaches the apparent ignition temperature of the rags it may burst into flame and result in fire. Water spraying can avoid such phenomenon.

25. Venting Fire is the process of inducting heat and smoke to leave a building as quickly as possible by such paths that lateral spread of fire and heat is checked, fire fighting operations are facilitated and minimum fire damage is caused.

1.7 Factors Contributing to Fire :

They are many. Some are easily detectable while some are hidden. Easily detectable factors contributing to fire are as under :

1. Easy availability of combustible material like rubbish, solvent, paper, wood etc.
2. Easy availability of air, oxygen or any oxidizing material.
3. Sources of ignition like spark, static discharge, contact of hot surfaces, friction etc.
4. Continuous running machinery without proper lubrication and maintenance.
5. Non flame proof electrical fitting in flammable areas.
6. Habit of smoking in flammable areas.
7. No provision of fire detectors in fire prone areas.
8. No provision of fire extinguishers in fire prone areas.
9. Open handling of flammable substances.
10. No compliance of fire safety rules. Some hidden factors contributing to fires are as under:
    1. Chemical reaction going out of control.
    2. Sudden stoppage of cooling media protecting flammable reaction or distillation of solvent.
    3. Trapping of metal parts, nails etc. in rollers or moving machinery giving sudden spark.
    4. Non availability of inert material on reaction of flammable substances.
    5. Sudden lightning from the sky.

1.8 Common Causes of Industrial Fire:

One study of more than 19000 fires in industrial plants revealed the following causes of fire:

Causes of Fire	%
Electrical	19
Friction	14
Foreign Substance	12
Open flames	9
Smoking & matches	8
Spontaneous ignition	8
Hot surfaces	7
Not determinable	7
Combustion sparks	6
Miscellaneous	5
Overhead materials	3
Static electricity	2
	100%

Another study of more than 25000 fires reported to the Factory Mutual Engineering Corporation from 1968 to 1977 gives following causes:

Causes of Fire	% Share
Electrical	22
Incendiaries (deliberate fire)	10
Smoking	9
Hot surfaces	9
Friction	7
Overheated materials	7
Cutting & Welding	7
Burner flames	6
Spontaneous ignition	5
Exposure	4
Combustion sparks	3
Miscellaneous	3
Mechanical sparks	2
Molten substances	2
Static sparks	2
Chemical action	1
Lightening	1
Total	100

Above percentage indicates the frequency of fire causes. It is not indicative of their relative importance at particular plant, place or property. These are old figures and old causes. Change in causes is always possible.

These causes can be subdivided in many sub causes as under:

Sparks may be mechanical, electrical, static, due to cutting and welding etc.

Hot surfaces may be due to bearings and shafting, stoves, heaters and small appliances, petrol, kerosene, LPG, acetylene or alcohol torches, potable furnaces, blow torches, smoke pipes, chimneys, flues and stacks, stationary heating devices, gas fired appliances viz. stoves, heaters, boilers, salamanders etc.

Spontaneous ignition is due to oxidation of fuel where air is sufficient but ventilation is insufficient to carry away the heat as fast as it is generated. Exposure to high temperature and, presence of moisture increase the tendency toward spontaneous ignition. We unslaked lime and sodium chlorate, rags or wash saturated with linseed oil or paint, sawdust, hay grains etc., and finally divided metals promote spontaneous ignition.

Hazardous chemicals and metals like phosphorous, sodium, potassium, oxidising materials nitro-cellulose film and pyroxylin plastics, fuels solvents, lubricants, wood, paper, cloth and rubber products, sprays and mists, LPG and other flammable or explosive gases are known for fire hazards.

Hyperboles, pyrophoric substances, adiabatic compression, radiation, catalytic action, natural sources, lightening, cooking equipment, electrical distribution and installation, static electricity, arson, rubbish, playing with fire, hand tools, pallet material storage and explosive dust, gas, vapour or air mixture are all causes contributing to fire.

Common causes of industrial fire and remedial measures are given in Table 13.3.

Table 13.3 : Causes of Fire & Remedial Measures

	Cause	Remedial Measure
1	Electricity	Standard and safe wiring, over load protection, double insulation and earthing on portable equipment, ELCB and waterproof cord in wet environment, use of proper flameproof equipment in hazardous area and periodical inspection.
2	Bad house keeping	Storing rubbish, waste, oil, grease etc. in a waste-bin with closed cover, regular cleaning and inspection, bund (dyke) to storage tanks of flammable liquid dust collectors, safe disposal, incineration.
3	Bidi-Cigarretts	No-smoking notices, separate smoking booths, checking of match box, lighter etc. at security gates.
4	Hot surfaces	Good insulation, fencing, ducting for smokes and flue.
5	Friction	Good lubrication, proper belt tension, alignment, dust removal, inspection and maintenance.
6	Excessive Heat	Cooling, temperature controls, trained operators and supervisors.
7	Welding cutting	Special place or partition, heat resistant floor, spark control, keeping flammable substance away, hot work permit, flammability test in tank before hot work, use of proper equipment.
8	Flame and combustion	Proper design, operation and maintenance, sufficient ventilation and ignition safety, heater insulation, hood, chimney, keeping flame away, trips and interlocks.
9	Self ignition	Keep environment cool and dry, necessary ventilation and protection, keeping ducts and passages of waste and smoke clean, separate store of highly flammable materials, not to put oil soaked rags on hot surfaces, lagging and cladding, small vessels, good house keeping.
10	Exposure	Barrier wall, sprinklers on fire path, wire glass in windows.
11	Ignition sparks	Proper equipment, closed combustion chamber, spark arrester on flammable vent and vehicle exhaust, flare, trip.
12	Mechanical sparks	Machine guarding to avoid entry of foreign particle, fencing, magnetic separator, non-sparking tools.
13	Molten hot substance	Proper equipment with handles, better operation, and maintenance non-mixing of water.
14	Static electricity (Due to belt drive, paper/ plastic reeling, human body, fluidized bed, pneumatic conveying, dust handling, liquid mixing, flow in vessel or pipe agitation etc.	Grounding, bounding, ionization and humidification, vehicle earthing while transfer through pipeline, earthing of vessel, equipment and piping, flow rate reduction, avoiding flammable atmosphere, splashing and settling, using earthed probe, antistatic device, conductive shoes and flooring, copper earthing with earth resistance less than 10 ohm additive to change liquid resistance, keeping filters away from storage tanks, extending inlet pipe up to bottom to avoid free fall of liquid, non-conductive parts and earthing of l4evel gauges, avoiding oil drops in water, small size of non-conducting plastic containers, using N2 instead of CO2 as inert gas, electrostatic eliminators on paper / plastic reeling machines, use of radioactive ionization etc.

2 CLASSIFICATION OF FIRE AND EXTINGUISHERS

Table 134 and 13.5 give the classes of fire (A to E) and portable fire extinguishers necessary for them.

Table 13.4 : Classes of Fire and Extinguishers

Class of fire	Description	Extinguishing Medium	IS No.
A	Fires involving ordinary combustible materials like wood, paper, textiles, fibres and vegetables etc. where the cooling effect of water is essential for the extinction of fires.	Water type (Soda acid)	934
		Water type (gas pressure)	940
		Water type (constant air pressure),	6234
		Anti – freeze types and	
		Water buckets	
B	Fire in flammable liquids like oils, grease, solvents, Petroleum products, varnishes paints etc. where a blanketing effect is essential.	Chem. Foam	933
		Carbon dioxide	5507 10474 2878 8149
		Dry Powder	2171 4308
		Dry Powder Mechanical foam	10658 10204
		Halon 1211	11108
		Sand buckets	
C	Fires involving gaseous substances under pressure where it is necessary to dilute the burning gas at a very fast rate with an inert gas or powder.	Carbon dioxide	2878 8149
		Dry powder Dry powder	2171 4308
		Halon 1211	11108
D	Fire involving metals like magnesium, aluminium, zinc, potassium etc., where the burning metal is reactive to water and which requires special extinguishing media or technique.	Dry powder	2171
		Special dry powder for metal fire	4861 11833
		Sand buckets	
E	Fires involving electrical equipment where the electrical non-conductivity of the extinguishing media is of first importance.	Carbon dioxide	2878
		Dry chemical powder	2171 4308
		Halon 1211	11108
		When electrical equipment is de-energised, same as for Classes A & B Sand buckets.	

* Class E is omitted is some literature (eg. IS: 2190)
Class K is suggested for fire involving cooking oils.

Note : For other IS see part 3.2 of this Chapter.

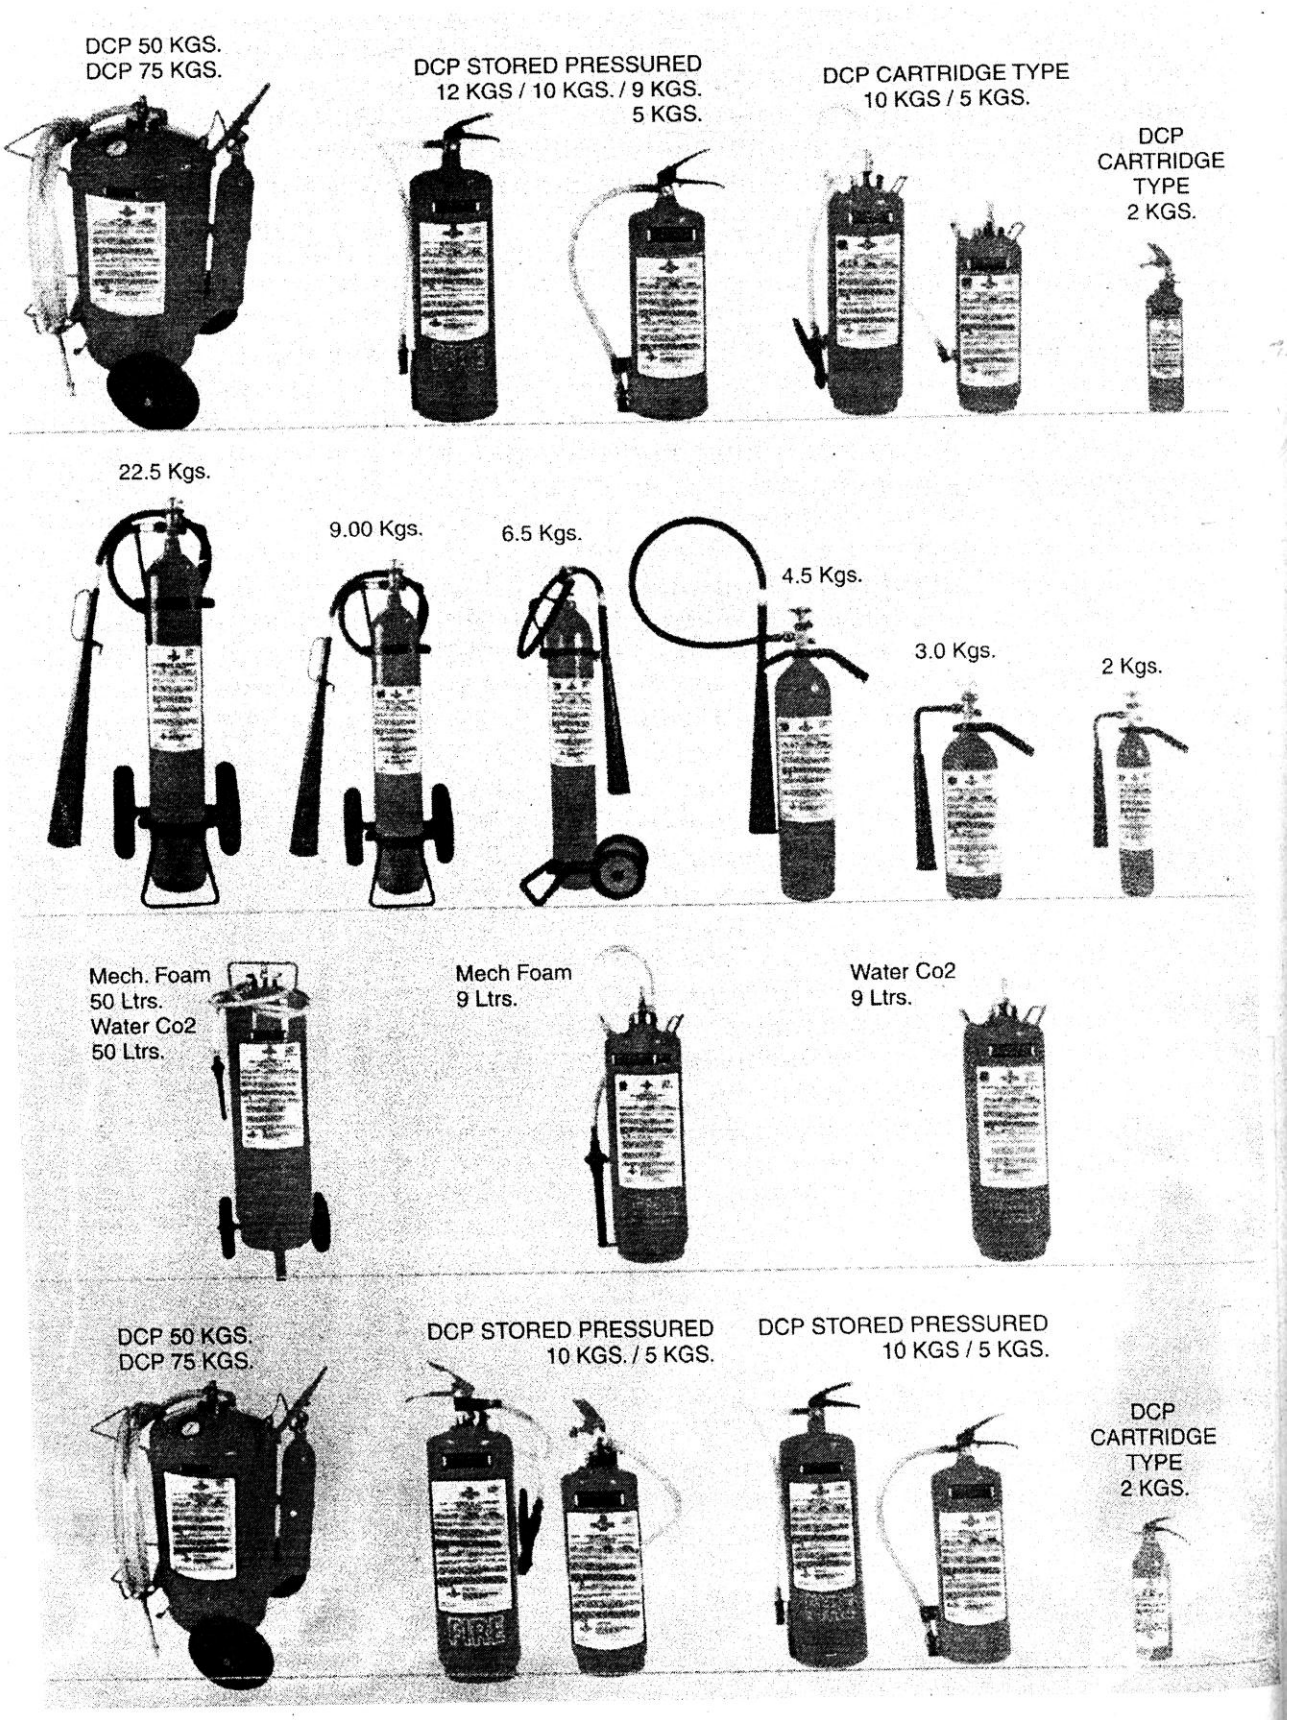

Fig. 13.3 Types of portable fire extinguishers.

Table 13-5 : Types of Extinguishers and suitability for Fire (IS:2190)

	Type of Extinguisher	IS No.	For type of Fires			
			A	B	C	D
1.	Water type (Soda acid)	934 4406	S *	NS *	NS	NS
2	Water type (gas cartridge)	940	S	NS	NS	NS
3	Water type (stored pressure)	6234	S	NS	NS	NS
4	Chemical foam type	933 5507 10474	NS	S	NS	NS
5	Mechanical foam type	10204	NS	S	NS	NS
6	Dry powder type	2171 10658	NS	S	NS	NS
7	Dry powder type	11833	NS	NS	NS	S
8	CO_2 type	2878 8149	NS	S	S	NS
9	Halon 1211 type	11108	NS	S	S	NS

* S = Suitable , NS = Not Suitable

See Part 5.4.1 for the use of fire extinguishers.

NFPA classification of Fire Extinguishers

NFPA 10 classifies fires and fire extinguishers into the following 4 types :

Class A : Fires in ordinary combustible material, such as wood, cloth, paper, rubber and many plastics, that require the heat-absorbing coolant effect of water or water solutions, the coating effects of certain dry chemicals that retard combustion, or the interruption or the combustion chain reaction by the dry, chemical or halogenated agents.

Class B: Fires in flammable or combustible liquids, flammable gases, grease and similar material that must be put out by excluding air (oxygen), by inhibiting the release of combustible vapor with AFFF or FFFP agents, or by interrupting the combustion chain reaction.

Class C : Fires in live electrical equipment. The operator's safety requires the use of electrically non conductive extinguishing agents, such as dry chemical as halon. When electric equipment is de-energized, extinguishers for class A or B fires maybe used.

Class D : Fires in certain combustible matals, such as Mg, Ti, Zr, Na, & K that require a heat absorbing extinguishing medium that does not react with the burning metals.

Class K : Class K fires involve cooking oils. This is the newest of the fire classes.

3 STATUTORY AND OTHER STANDARDS

3.1 Statutory Provisions:

Section 38 of the Factories Act requires to prevent outbreak of fire and its spread, both internally and externally and to provide and maintain (1) Safe means of escape for all persons in the event of fire and (2) The necessary equipment and facilities for extinguishing fire. Workers' training is also required.

Rule 66 of the Gujarat Factories Rules (GFR) requires sufficient fire exits, width and height atleast I and 2 meters respectively, one staircase for less than 20 workers on any floor and two staircases for more than 20 workers or explosive or highly inflammable materials on any floor and the availability of fire escape stair within 45.7 m. along the line of travel and at an angle less than 45° from the horizontal.

Rule 66A of the GFR : It provides as follows:

Various fire fighting arrangements are suggested under 13 heads. Two Schedules are given to list first aid Fire Fighting Equipment (FFE) and equipment to be provided with Trailer Pump. Their brief account is as under:

1 Serious Fire and Explosion Hazards :

1 All processes, storage, equipment, plants etc. should be in segregated buildings.
2 Minimum number of employees should be exposed at a time.
3 Fire prone area should be separated by fire resistant walls. It should be so constructed that in case of fire, it can be easily isolated.
4 Ventilation ducts, pneumatic conveyors, AC plant etc. should have flame arrester, flameproof damper or automatic fire extinguisher electrically interlocked with heat sensitive smoke detectors.
5 For storage of material, passage width between two piles should be more than 90 cm. and clearance between ceiling and the pile top should be more than 2 mt.

2 Access for fire fighting :

1 Unobstructed layout of plants and building for easy fire fighting.
2 Doors and windows on external walls for easy access inside the building.

3 Protection against lightening :

Lightening arrester shall be provided for
1 Building having flammable or explosive material.
2 Storage tanks for flammable liquids.
3 Grain elevator to avoid dust explosion.
4 Tall structure where gas, fume, dust, lint et may be present.
5 Electrical switchyard, outdoor transformers and substations.

4 Precautions against ignition :

Accumulation of explosive air mixture shall be avoided and prevented from fire by

1. Segregated electrical machinery or b keeping them flame or explosion proof.
2. Avoidance of static charge to a dangerous extent.
3. Non-ferrous shoes to avoid sparks b] friction.
4. Prohibition of smoking, lighting or carrying matches or lighters etc.
5. Transmission belts without iron fasteners

6. Avoidance of open flames, sparks, over heated surfaces, radiant heat and ignition from physical or chemical reaction.

5 Spontaneous ignition:

1. Avoid air pocket and ensure good ventilation.
2. Safe distance in heaps of material susceptible to fire.
3. Open ground storage at minimum distance of 10 mt from process or storage building

6 Gas Cylinders:

1 Rooms shall have adequate ventilation.

2 Open storage to be protected from direct sun-rays, excessive heat, continuous dampness and away from highly flammable substances, furnaces and hot processes.

7 **Storage of Flammable Liquids :**

1 Quantity minimisation.

2 Suitable containers with closed covers.

3 Liquid of P.P. below 21 °C shall not be stored more than 20 litres in any room.

4 Fire resisting construction with fire walls and self closing fire doors.

5 Storage of large quantities as per Petroleum Rules, 1976. Underground storage is preferred.

6 Steps to pre vent leakage.

8 Flammable dust, gas, vapour, waste etc. :

1 Steps to remove or prevent accumulation to dangerous extent.

2 Daily disposal.

3 Metal containers with covers.

9 Fire Exits:

An exit includes doorway, corridor and passageway. It should provide continuous (unobstructed) and safe egress (departure) by fire resisting wall. Lifts, escalators and revolving doors are not considered as "exits".

Some specifications of Fire Exits are as under:

1. They should be sufficient in number.
2. Clearly visible and illuminated. Lighting independent from normal power supply.
3. Marked by language understood by the workers.
4. Iron or spiral ladders not allowed.
5. Doors or roller shutters near lift or stair entrance should be of fire resisting type to prevent spread of fire or smoke.
6. All exits should reach open space leading to a street.
7. Should not be located at a travel distance exceeding 30 mt. For high hazard storage, distance should not exceed 22.5 mt and at least two escape routes should be available in each such room. Such more exits should be remotely placed from each other and providing access in separate directions.
8. Occupants per exit of 50 cm width shall be 50 for stairs and 75 for doors.
9. Area of 10 m2 per person or actual number of occupants as stated in (8) above, whichever is more, shall be considered to determine number of exits.
10. Every floor above or below the ground floor shall have minimum two exits. One of them should have internally enclosed stairway.
11. Minimum dimension of doorway - width 100 cm, height 200 cm.

12. Exit doorways should open outwards at all times. In an open condition it should not reduce the width of stairway or landing less than 90 cm. Overhead rolling shutters not allowed for this purpose.
13. Exit door should have a minimum landing of 1.5m x 1.5m on the same floor before opening on any stairway.
14. Exit door should be openable without key.
15. Width of corridor/passageway should no be less than total widths of all exit door opening on it. Height of corridor passageway shall be more than 2.4 mt.
16. If a staircase is arranged round a liftway, the fire resistance (rating) of the lift way should be more than that of the staircase.
17. Hollow combustible construction is not permitted.
18. Staircase dimensions -

Minimum width	100 cm
Minimum width of tread	025 cm
Maximum height of riser	019 cm
Minimum height of hand rail	100 cm

Treads should be non-slippery
Number of risers not more than 12 per flight

Hand rails should be firmly supported.
19. Use of spiral staircase is limited to low occupant load and for a building not higher than 9 mt. Its diameter shall, be more than 3 mt. with adequate headroom.
20. At least one fire door on the same floor should be of self-closing type.
21. Floor area on the opposite (shelter or refuge) side of a horizontal exit should be sufficient to accommodate occupants of the floor area served, allowing more than 0.3 1712 per person. At least one exit should directly lead to the street.
22. Ramp of slope I in 8, or less, be provided to connect floors of different levels.
23. A staircase may be substituted by a ramp of slope I in 10, or less. Surface of ramp should be non-slipping.
24. If the building capacity is more than 500 persons or if more than 25 persons are employed above or below the ground floor, an automatic or manual fire alarm system shall be provided.

10. First Aid Fire Fighting Arrangements :

Suitable and sufficient first aid fire extinguishers as prescribed in Schedule I (similar to Table 13.4) shall be provided and maintained. They should confirm to IS. Their numbers and types are classified for fire class A to E. They should be similar in a shape, appearance and method of operation. They should be placed in conspicuous place readily and easily accessible. Their bottom should be 75 cm above the floor level. They should be charged regularly and recharged immediately after discharge. Water and sand should be clean. One 9 litres water bucket should be provided for every 100 m2 of the floor area or part thereof. For details see Sch.l,Rule66A,GFR.

11. Other Fire Fighting Arrangements :

A formula is suggested to calculate the amount of fire water. If this requirement is 550 litres/min or more, power driven trailer pumps of adequate capacity are prescribed. Pumping capacity be reduced by 25% if fire service is available within 3 km. Each trailer pump should have equipment stated in Schedule-11. They should confirm to IS.

It should be housed in a separate shed close to a principal source of water and near the main risk of the factory. Towing attachment; one for every 4 trailer pumps is required, if manual pulling and placement of pump is not possible.

Water should be sufficient to supply at least for 100 minutes. At least 50% of the water requirement calculated by the formula or 4,50,000 litres whichever is less, should be stored in static tanks (each of 4,50,000 litres or more) distributed round the factory and in fire prone area. Diameter of main pipe should be more than 15 cm, capacity more than 4500 lit/min and pressure more than 7 Kg/cm^3

12. Fire Fighting Team, Drill etc. :

All fire fighting equipment (portable and fixed) shall be in charge of a trained person. Their number should be sufficient and provided with necessary clothing and equipment including helmets, belts, gum boots.

Quality of personal protective equipment (PPE) should confirm to the IS.

Fire drills are required at least once in two months or as often as necessary.

13. Hydrants and Sprinklers:

Fire hydrants and automatic sprinklers shall be in addition and not in substitution of above requirements.

See Petroleum Rules 2002 for fire safety of petrolium.

3.2 Indian Standards :

Fire : IS on fire safety are many. They can be selected as per requirement from the BIS Handbook. A few standards are stated below :

Glossary of terms for FFE 7673, 8757, Fire appliances, first-aid selection, installation and maintenance 2190, Fire bell 928, Fire brigade trailer pump 942, 943 & 944, Fire control equipment 10548, Fire detectors, heat sensitive 2175, Fire escape wheeled 931, Fire extinguishers, portable, CO_2, type 2878, Dry powder type 2171, Mechanical foam type 10204, 933, 4989, 4562, Water type (gas cartridge) 940, Water type (stored pressure) 6234, Water type, bucket pump 6924, gas pressure 940, Soda acid type 934, Fire extinguishing system, CO_2, fixed 6382, Fire fighting appliance, selection, operation and maintenance 5896, Extension ladders 930, Flame and heat resistant suit 7612 Water tender type A for fire brigade use 948, Gas cartridge for use 4947, Refills for portable fire extinguishers 5490 (Part I to 4), Twin CO_2 fire extinguishers (trolley mounted) 8149, 150 litre fire engine, foam type 10474, Higher capacity dry powder (trolley mounted) 10658, Portable-Halon 1211 type 11108. Fire tenders 946 to 951, 954 to 956, 2930, 6067, 10460,10993.

Automatic fire detection and alarm 2189, Heat sensitive fire detectors 2175, Hydrants in multi-storey building' 3844, Water supplies for fire fighting 9668, Automatic sprinkler heads 9972.

Hoses, Couplings, Accessories - 636, 884, 901 to 910, 926 to 928, 5612, 5714, 6026, 8090, Hydrant-stand post type 908, Stand post water monitor 8442, Hydrants and hose reels 3844.

Fire safety in building - 1641 to 1644, 1646, 1891, Ginning-pressing factories 2726, Welding & cutting 3016, Cotton textile mills 3079, Jute mills 3836, Storage & Warehouse 3594, fire resistance test 3808, 3809, tea factories 4886, fire retardant plywood 5509, saw mills and woodworks 6329, test for ignition temperatures 7820, paint and varnish factories 9109, chemical industries 11457, flour mills 13045, cable runs 12459, life saving equipment symbols 10548, LPG storage installations 6044, graphic symbols, 12307, safety signs 12349, gas testing flame safety lamps 7577.

Explosion : Some IS on explosion are: Classification of hazardous areas 5572, Exploders 9826. Explosion hazards - prolection against 8607, Explosive and accessories, blasting, tests 6609, Explosive atmosphere - electrical equipment 8239 to 8241, 7693, 7724, 8945, Explosive industry 11783, Explosives or pyrotechnic - glossary 10081, Packages 10212, dextrin 12276, Potassium nitrate 301, Sodium nitrate 12681, Ammonium nitrate 4668, Barium nitrate 4396, Aluminium powder 438, Barium chromate 7886, Lead chromate 7602, Manganese dioxide 5713, Calcium carbonate 7633.

See also Part-3 of Chapter-11 for electrical equipment to be used in flammable/hazardous areas. IS 5572 for classification of hazardous areas having flammable gases and vapours and IS 5571 for selection of electrical equipment for such areas are most relevant.

3.3 Guidelines of Regional Tariff Advisory Committee (TAC) :

Fire Protection Manual or Booklet on rules governing fire protection systems, was first published in 1906 by the Calcutta Fire Insurance Association and the edition of 1993 is published by the Oriental Insurance Co. Ltd., Bombay-20. The Committee means the Regional Committee at the regional office of the Tariff Advisory Committee .(TAC). The subjects of manual are as under:

Part I: Internal Appliances, Fire engines/Trailer pumps. Automatic fire alarm systems and Hydrant system.
Part II : Water Spray Systems.

Rules for Automatic Sprinkler Installations are also available.

Table of Contents of Part 1 is as under:

Fire engines, pumps, alarms and hydrants (TAC Rules):

1. Requirements regarding submission of plans
2. Procedure to be followed in the case of application for discounts
3. Committee's inspection staff
4. Internal appliances
   4.1 Hand appliances
   4.2 Small bore hose reels
5. Mechanically driven fire engines and trailer pumps
6. Rules regarding automatic fire alarm system using heat detectors
7. Hydrant service
   7.1 General
   7.2 Classification of occupancies
   7.3 Water supply
   7.4 Pumps
   7.4.1 General
   7.4.2 Steam driven pumps
   7.4.3 Electrically driven pumps
   7.4.4 Petrol or motor spirit engine driven pumps
   7.4.5 Compressor ignition driven pumps
   7.5 Mains
   7.6 Hydrants/fixed monitors
   7.7 Hose pipes and nozzles
   7.8 Foam compounds
   7.9 Fire fighting personnel
   7.10 Maintenance
   7.10.1 Pumps
   7.10.2 Mains
   7.10.3 Hydrants

Table of contents of Part II is as under:

Water Spray Systems (TAC Rules):

3.2.3 General Layout and Design
3.2.3.4 Projectors
3.2.3.5 Fire Barrier Walls
3.2.3.6 System Design
3.2.4 Detection system for transformers
3.2.4.1 Outdoor Transformers
3.2.4.2 Indoor Transformers
3.3 Miscellaneous protection

Section 4 - Medium Velocity Water Spray Systems
4.1 Introduction
4.2 Water Supplies
4.3 Pumping Capacity
4.4.4 Design density
4.4.5 Layout of protection network
4.4.5.7 Equipment protection
4.4.6 Structural protection
4.4.7 Piping and supports
4.4.8 Hydraulics
4.4.9 Detection system
4.5 Protection of Horizontal Cylindrical Storage Vessels
4.6 Protection of Vertical Cylindrical Storage Vessels
4.7 Protection of spherical vessels
4.8 Cable Galleries and Tunnels
4.9 Conveyors .

Section 5 - Pre-commissioning Procedures
5.1 Pre-commissioning and acceptance test
5.2 Periodical testing and maintenance
5.3 Periodical testing and maintenance chart
5.4 Hydraulic calculations General

Section 6 - General information
6.1 High velocity water spray system
6.2 Medium velocity water spray system
6.2.4 Scope of Applications
6.2.4.17 Limitations

Appendix -I, II & III

See Part 5.4.2 for further details of Water Spray System.

See Part 3.3 of Chapter-11 for the TAG Regulations for the Electrical equipment of buildings. TAC rules for Segregation of Buildings are also available.

3.4 NFPA Code (NFC) :

NFPA means National Fire Protection Association of USA. NFPA is an internationally recognised body and their standards, codes, and manuals are followed not only by American Government and industries but also by other countries in the world. NFC means National Fire Code.

The code indicates (1) relative risk to health (2) flammability (3) instability and (4) possible specific hazards (symbols) . Each of the first three aspects (1) to (3) is assigned a value in the range 0-4, the higher number indicating higher risk.

The content of the NFPA code (NFC) is vary exhaustive. A few subjects of 1990 NFC contents are given below:

Accreditation of Fire Protection Education Programs, Air operations for forest, bush and grass fires. Aircraft fire investigator's manual. Fire fighting at airport. Airport/community emergency planning, Alternative approaches to life safety. Ammonium nitrate-storage of. Baled cotton storage. Blower and exhaust systems. Building materials - test methods, fire retardant coatings etc.. Fire fighting in specific chemical industries. Protective clothing for fire fighting, Emergency voice/alarm. Cutting and welding processes. Fire extinguishers - different types. Electrical code - National, Electrical safety requirements, Explosion prevention systems. Fire department Occupational safety and health programs. Fire dept. – Safety officer. Fire detectors, hose etc.. Fire Inspector, Fire officer. Fire Prevention Code, Fire pumps. Fire services. Fireworks, Flammable and combustible liquids, gases, solids. Floor covering systems. Foam systems. Footwear, Fuel Gas Code-National, Hazardous materials incidents responders. Health care facilities. Homes and camps in forest areas. Hydrants, Life Safety code. Lightning Protection code, LNG and LPG storage and handling. Marine terminals, Breathing apparatus. Personal alert safety systems (PASS) for fire fighters. Places of worship. Property survey manual. Records-protection of , Roll paper storage. Roof coverings - fire tests of. Signalling systems. Smoke and heat venting. Spray and sprinklers systems. Static electricity. Symbols - fire protection, Truck fire protection. Venting of deflagrations. Water supplies. Wetting agents. Wildfire control. Wood dust explosion and Zirconium production processing.

Thus, NFPA code gives standards for many subjects on fire.

4 DESIGN FOR FIRE SAFETY

4.1 Fire Resistance of Building Materials :

In flammable area when building materials and paints are used, they should have good fire resistance. Steel and masonry are fire resistant materials. Fire resistive structural material should be selected depending upon the type of fire possible. There are three types of materials : (1) Non-flammable viz. metals, brick, clay, asbestos, concrete, cement, gravel, ceramics, sand etc. (2) Hardly flammable viz. staw brick, dry gypsum plaster, fibreboard, linoleum etc. (3) Flammable viz. organic origin such as wood, cardboard, felt, paper etc. As far as possible non-flammable material should be selected.

Fire or flame resistance is the capacity of structural element to perform its load-bearing and enclosing functions i.e. to retain its strength and ability to withstand action of fire, for a particular time during fire.

The fire resisting limits of buildings should be high to ensure safety and escape in case of fire. Such limits are measured in terms of time (h) from the start of the fire to the indication of any crack or loss of load carrying capacity (collapse) .or rise of excessive temperature. The fire resisting limits also depend on the size (thickness and cross section) and the physical properties of the building material. For example, 12 cm thick wall can withstand fire for 2.5 h and a 25 cm thick wall for 5.5 h. Fire retardant coatings on wood and flame proofing of fabrics are useful to some extent.

IS-.1642, 3079, 3594, 3808, 3809 and 6329 provide further details.

4.2 Fire Safety of Building, Plant, Exit, Equipment etc. :

The building should be protected both horizontally and vertically from spread of fire through floors, stairs, walls, ventilating ducts etc. Fire« resistant barriers can be used for this purpose.

A fire stopping is a fire-check wall of nonflammable material with a fire resistance limit of at least 2.5 h. It may be blind or with fire resisting doors or gates. Stopping can be internal, external, roof and separate (stand alone) fireproof walls. They are constructed to intersect the floors, ceilings and roofs with fibreboard of 30 cm over roofs from non-flammable materials. Fire-resistance limit of doors and gates in stopping should be more than 1.5 h. The total area of such openings should not be more than 25% of the total surface area of the stopping.

Where the construction of stopping is not possible, fire check-zones (strips of non-flammable materials) should be provided to divide floors and walls into sections more than 6 m wide. Ventipanes or smoke escape windows should be provided to facilitate smoke removal during fire. Exits and escape ways should be as per statutory requirement. Width of escape should be more than a meter and should increase depending upon the maximum persons likely to use it.

High fire risk areas; storage, packing and dispatch areas, boiler and fuel rooms, transformer room, kitchen and car parks should be separated by fire resistant construction. Storage of flammable liquids and gases should be minimum possible. Gas cylinders should be stored either in open air with shade or in a room of non-flammable construction and ventilated permanently to the external air. Fire hazards of storage of explosive and flammable substances, electrical equipment, static electricity, heating processes, painting, sparkling etc., should be foreseen and fully protected.

Lightening protection of buildings is most important as the heavy electric charge (up to 150000 KV and 200 KA) may prove destructive causing fir6 and explosion in the ground structure. Appropriate lightening arrester (protector) should be fitted higher than the highest' object and covering the lightening protected zone. The resistance of the grounding device should be less than 10 or 20 ohms depending upon its category.

Fire safety should be well thought of from siting: and location stage to the maintenance stage as follows:

Siting and location : sufficient space, water and emergency facilities, effects of past disasters, location of process areas for quick vapour dispersal and location of control rooms.

Plant layout : Segregation of hazardous processes and storage, drainage and compliance of statutory standards.

Design and Construction : Relief valves, by-passes, rupture discs, explosion vents, safety interlocks, flame arresters, flameproof fittings, selection of material, fire resistant construction, underground storage.

Plant Operation : Limited storage of flammable materials, good housekeeping, good ventilation, work permit system, emergency action plan and training of employees.

Plant Maintenance : Reliability and monitoring procedures, inspection, testing and preventive maintenance, spares availability and maintenance of fail-safe safety devices.

IS-.1642, 3594, 6329,1646 and 15:2190 must always be followed for material and details of construction of buildings, storage and use of portable fire extinguishers.

See Part 3.1 for statutory detail.

5 FIRE PREVENTION AND PROTECTION SYSTEMS

A broad classification of fire safety system is explained below:

- **Fire Safety**
  (Existence of fire hazard and awakening of fire consciousness of the management)
- Fire Prevention
  - Detection by Detectors (alarms)
  - Elimination of hazard or source of ignition
  - Control over combustibles in storage, handling and process
- Fire Protection
  - Fire resistant design of buildings, equipment , means of escape and fixed installations
  - Suppression, Extinguishment or control by various extinguishers
- Fire Fighting
  - Equipment and hardware
  - Staff, training and readiness

Above steps are explained below :

Fire prevention : This is an activity directed towards elimination of possible and potential sources of fires. It mainly indicates measures to avoid inception of fires. Where the source cannot be eliminated or avoided, exercise sufficient control to ensure its safe usage. The activity also involves control overhandling, storage and process of combustibles.

Fire Protection : This is an activity directed towards limiting the spread of fire to its place of origin by resorting to design , compartmentation, utilisation of fire resistive materials, provisions of safe means of escape, control by portable and fixed automatic extinguishing systems.

Fire protection being wider term includes fire prevention stated above and fire fighting mentioned below. Fire detection, prevention, extinguishment or control, all aim to protect plant, people and property.

Fire protection engineering is a highly developed specialised branch of engineering and a degree of B.E. (Fire) is awarded in college at Nagpur. Such qualified fire engineer and if he is not available, qualified safety officer should look after fire protection activities.

Fire Fighting : This is an activity directed towards provisions of proper fire fighting equipment, proper maintenance, personnel with proper organisation, training programme and readiness to fight fire.

Salvage : This is an activity to minimise the damage due to fire, smoke and water to the uninvolved property.

Return to normalcy : This is contingency plan where the various steps are laid down to bring back the industry, to productive stage from the crippling damage due to the fire.

Some systems are as follows :

5.1 General Control Measures :

Main steps in controlling fire are :

1. To detect the fire at the earliest possible.
2. To confine the fire, and
3. To extinguish the fire at the earliest possible.

Six fundamental principles of fire prevention and reduction are:

1. Fire prevention engineering.
2. Regular periodic inspection.
3. Prevent the start of fire.
4. Early detection and extinguishment.
5. Limiting the spread and damage due to fire and fire control.
6. Prevention of personal injuries from fire or panic, including prompt and orderly evacuation of personnel.

Based on fire chemistry explained in Part 1.3, four fundamental methods of fire control are :

1. Eliminate the oxygen of the air.
2. Remove or shut of the fuel supply.
3. Reduce the temperature below the kindling point and '
4. Break the chain reaction continuing the fire.

To achieve the most efficient fire protection system, involvement of the building designer(architect) and contractor, local authority (urban planer), interior designer, structural engineer, electrical engineer, fire detection system, manufacturer/supplier, building safety engineer and local fire marshal is necessary.

An automatic sprinkler system becomes most useful as it starts initially. Early detection of fire, speedy response, trained staff, emergency planning and preparedness and fixed extinguishing system based appropriately on fire load are the essential key points in any fire fighting arrangement.

To stop the fire occurrence, following fire prevention activities are desired:

1. **Fire Inspections :** Fire prone area, equipment and conditions should be inspected. Periodicity may be daily, weekly, monthly etc depending on requirement. A check list should be designed best fitting to the premises and activities. It should include checking of poor housekeeping, accumulation of dust or flammable material, readiness of fire hydrants, hoses, sprinklers, alarms, detectors, water storage, pumps/engines, charged portable fire extinguishers, foam, carbon dioxide, DCP and other protection systems, fire doors, aisles, exits, control room, electrical equipment, hot processes and machinery, and placement of fire fighting and personal protective equipment, tools etc.

2. **Hot-work permits :** Many fires have taken place while doing hot-work in flammable areas. A hot-work permit form and tag should be designed and used to check all points in advance and to take necessary precautions. Following steps are useful:

    1. Check the area where work is to be done.
    2. List steps, equipment and procedure necessary and prepare the permit.
    3. While at work, constant watch (supervision) is necessary if hazard exists.
    4. Standby workers should be ready on the spot with fire extinguishers.

5. Isolate flammable materials (stop its flow if possible) from sources of ignition.
6. Isolate sources of ignition by all possible ways.
7. Stop unauthorised use of spark producing equipment nearby.

3. **Fire brigade and Drills :** A plant fire brigade of qualified and trained personnel is necessary to fight fire till outside public fire brigade arrives and helps.

Regular scheduled training of all members of the unit should be carried out. On-site emergency plan involving other employees should be prepared and rehearsed.

4. **Fire-retardant treatments:** Such coatings can be applied on wood, plastics, paper etc. to withstand flame. Fire rating of such substances should be studied for comparison to the nontreated material. Chemical treatment to fabrics reduces their flammability. Flame retardant canvas can be used up to 250 °C. For higher temperatures, asbestos or chrome leather is preferred. Water gel compound can be used to soak a cloth-piece to make it fire-retardant. It should be noted that all such treatments are temporary and not foolproof.

5. **Communication :** After noticing a fire, fast communication is necessary, to call for fire fighting team and to alert occupants to the emergency. Well arranged bells, fire call buttons or a coded computerised fire alarm system are essential. Equally important is the training of persons to react after hearing the alarm.

6. **Protecting nearby buildings :** After noticing a fire, it is also necessary to protect the adjacent plant and building by closing windows, positioning personnel at each window nearest the fire, with fire extinguishers or fire hoses and stationing fire fighters on the roof of the exposed building with hose lines to keep the roof wetted and to put off any local fire.

7. **Assessment of Fire Risks :** For effective fire protection, it is necessary to analyse and evaluate the fire risk. Such process aims at -
   1. Recognition of hazards and potential hazards.
   2. Evaluation of hazards and expected losses.
   3. Evaluation of the proposed counter measures.

   A fire risk survey should be carried out to list fire hazards. Site, building construction, plant contents, management factors, people factors, fire protection system and post fire activities are the areas to be covered. Highly flammable material and processes, smoke and toxic gas generation, people likely to be affected, fire load calculation and specific nature or industry are relevant points.

5.2 Fire Detection and Alarm Systems:

Various types of detectors are available operating on principles of thermal expansion, thermoelectric sensitivity, thermo conductivity or photosensitivity to detect presence of smoke, increase in temperature, light intensity or total radiation. Their types are : Thermal expansion detectors. Radiant energy detectors. Light interference detectors and Ionisation detectors. They should be properly located depending upon their range. They simply give alarm and cannot extinguish fire. They make us alert for fire fighting.

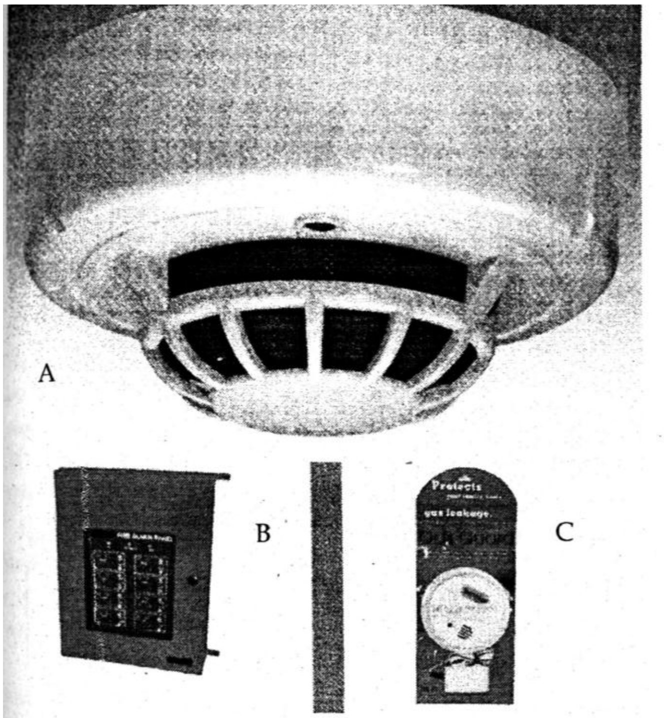

Fig. 13.4 Fire detectors (A & B) and LPG detector (C)

Fig. 13.4 Fire detectors (A & B) and LPG detector (C)

Though fire detection and alarm systems are separate systems but the latter has to operate just after the former operates. Therefore they are considered together. IS 2175 and 2189 also deal with them together.

Two main functions of any fire detection system are
1. To give alarm to start up extinguishing procedure, and
2. To give early warning to area occupants to escape.

It is wrong to speak 'fire detectors'. Actually they detect sensible heat, smoke density or flame radiation to operate before actual fire follows. Their 'sensor' detects measurable quantity of these parameters. A decision making device coupled with the sensor, compares the measured quantity with a predetermined ' value, and when it is different, an alarm is sounded. A detector both detects and signals.

Human being is a good detector as he can act m a flexible way i.e. run away, put out the fire or call the fire department. No other detector can work in such selective manner.

Selection of the type of detector is important For example, low risk areas need thermal detectors, a ware house may have infrared and ionisation detectors and a computer area requires ionisation or combination detectors.

Location and spacing should be determined to obtain the earliest possible warning.

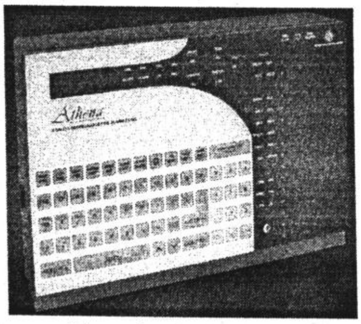
Sensitivity, reliability, maintainability and stability are important factors for selection.

Fire process has four stages - incipient stage, smouldering stage, flame stage and heat stage. Many types of fire detectors are available for various situations and useful at different stages of a fire (see part 1.4).

Thermal detectors are of fixed temperature detectors, rate-compensated thermal detectors, rate of rise thermal detectors, line thermal detectors and the bulb detection system.

Smoke detectors are of photoelectric type and are of two classes - The beam photoelectric or reflected beam photoelectric detectors.

Flame detectors are of infrared (IR) or ultraviolet(UV) type.



Fire alarm system

Ionisation (combustion products) detectors are the single chamber or dual chamber ionisation detector and the low-voltage ionisation detector.

Fire Alarm system may be separate to run manually or connected with fire detectors and operable automatically. All workers must be made aware of the sound pattern and its meaning. Fire alarm sound should be distinguishable from other sound m that area. It should be clearly audible to all facility personnel. Sound for beginning of fire and end of fire should be kept different.

5.3 Fire Load Determination :

After fire detection and alarm system and before fire suppression or extinguishing system, it is necessary to know the fire load so that based on that, amount of fire extinguishing system can be designed and number of fixed and portable fire extinguishers can be calculated.

Fire load is the concentration or amount of combustible material in a building per sq. mt. of floor area. It is defined as the amount of heat released in kilo calories by the fuel per square meter area of the premises. Fire loads are useful to calculate the water requirement to quench the fire, as when water comes in contact with burning surface it absorbs heat. I cc of water absorbs I cal of heat when the' temperature is raised by 1°C. The fact should also be considered that all the fuel does not burn at a time and all the water does not absorb heat as it flows away.

Bombay Regional Committee (BRC) on fire has prescribed rules for fire load calculation. Fire loads are calculated to assess potentiality of fire hazard, need of amount of fire prevention and protection systems (e.g. water or other agent) and amount of premiums required for fire insurance. Fire load classification is as follows:

Low fire load	-	Less than 1 lakh B.Th.U.
Moderate fire load	-	Between 1 to 2 lakhs B.Th.U.
Higher fire load	-	More than 2 lakhs B.Th.U

See Rule 66A(11) of the Gujarat Factories Rules for area calculation by ABCD formula.

For fire load calculation see-last Part 8.

5.4 Fire Suppression or Extinguishing Systems :

Mainly three methods are used in all such systems : (1) Starvation or isolation i.e. shutting off or preventing the flow of fuel and blanketing the fire surface with form to .seal air-vapour mixture (2) Cooling by application of water, foam or dry chemical powder and (3) Smothering by applying inert gas (to reduce oxygen), steam, dry chemicals or vaporising liquids such as C0,„ frecn FE 1301, methyl bromide etc.

Two types of extinguishers are used, portable and fixed.

5.4.1 Portable Fire Extinguishers :

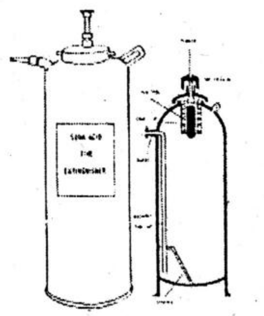
In addition to the fixed fire installations stated in next part, portable (first-aid) fire extinguishers are always desirable for quick manual use on small fires and fort the period till automatic equipment or outside fire fighters work. All such extinguishers should be (1) of reliable make, standard (IS) and properly identified (2) of right type depending upon the class of fire (3) sufficient in number (4) properly located where they are necessary and readily accessible (5) recharged periodically, inspected and maintained in good working condition and (6) known by the operators who are trained to use them.

Their types are : (1) Water type (2) Soda acid type (3) Carbon dioxide type (4) Foam type (5) Dry chemical powder type and (6) Vaporising liquid type. IS:2190 is most useful for selection, installation and maintenance of portable first aid fire extinguishers. Details of these six types are also given in IS:940, 6234, 934, 2878, 933 and 2171. Tables of their suitability according to class of fire and scale i.e. their range or area coverage arc also given therein. Based on them, number of extinguishers can be determined. Methods of their testing and test form are also prescribed. Refer them for further details.

See Table 13.4 and 13.5 for selection of portable extinguishers.

For small fires mostly portable fire extinguishers are used. They are explained below in brief:

(1) Soda Acid (Water Type) Extinguisher:



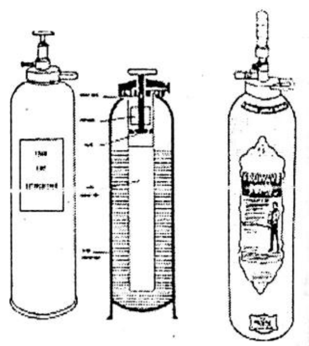
Soda Acid (Water type) extinguisher

This extinguisher is useful for class A fire (wood, paper, fabrics, rubbish etc.). It should not be used on fires of electricity, oil, chemical or metal. It is available in both the shapes cylindrical and conical.

Its normal capacity is 9 Ltr (weight 14 Kg) and to be used in a range of 6 to 8 mt. It consumes within I to 1.5 minute. It should be checked every 3 months.

It is held vertically up (not inverted). By standing 4 to 5 mt. away from the fire, after opening the plunger, it is struck on the hard surface. A small H„SC) (Sulphuric acid) bottle breaks and due to its mixture with soda bicarbonate solution, C0„ (Carbon dioxide) is generated. Pressure of CO, throws water at a distance. Its handle and bottom are held by two hands and water is sprayed on fire to extinguish it.

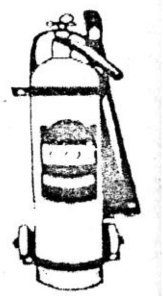
(2) Foam Extinguisher:



Form ty

It is used on class B small fires. It: should not be used on electrical or metal fire. It is available in 9 Ltr cylinder and used in 4 to 6 mt range. It consumes within 1.5 minute. It is available in wheel mounted trolley of 18 Ltr and 150 Ltr capacity for longer use. It should be checked every 3 months.

By standing 3 to 4 mt away from the fire, the plunger is. pulled up and turned right up to a slot. It is shaked by turning 180" twice. Then it is held inverted. By chemical reaction CO is generated which throws foam outside. The foam is not thrown directly in fire but it is thrown on nearer hard surface so that because of striking further foam is generated and spread on burning surface. It stops oxygen availability for burning and controls the fire. Foam is effective up to 120 °C temperature only.



CO_2 Extinguisher

(3) CO_2 (Compressed gas) Extinguisher :

It is useful on class E i.e. electrical fire because CO_2 is nonconductive gas. It can be used on class B and C fire also, as it diminishes oxygen to control fire. It is not advisable to use it in a closed room as more CO_2 may be inhaled. Therefore open doors and windows before using it in a room. It should not be used on fires of metal, sodium, potassium and metal hydrides.

It is available in 2 kg ,4 kg, 6.8 kg and 22.5 kg capacities. Small cylinders have handles and big cylinders have wheels. Its range is 1 to 1.5 mt. CO_2 pressure is at 64 to 70 bar. It should be checked every three months.

(4) Dry Chemical Powder (DCP) Extinguisher :

This can be used on any class of fire. Therefore it is known as 'universal type extinguisher'. It is generally used on fire of flammable liquid. It is not effective on fire of benzene, ether, EO and CS_2 For metal fire, special powder extinguishers are available. 1,2,5 and 10 kg extinguishers in cylinders and 68 kg in wheel models are available.

A 10 kg cylinder is consumed within 12 to 15 seconds and its range is 3 to 6 mt. A 68 kg cylinder is consumed within I to 1.5 minute and its range is 6 to 8 mt. Both should be checked at 3 months interval.

By standing 6 to 8 mt near the fire, the cylinder is shacked twice by turning 180°, a safety clip is removed and plunger is pressed or struck so that CO, bottle breaks and it throws dry chemicals out. The dry powder blankets the burning surface, stops 0, contact and CO, coming out also diminishes 0 proportion. Therefore fire is controlled by double action. Its long nozzle should be turned in wind direction like a broom.

DCP extinguisher

(5) Halon Gas Extinguisher (Halon Alternatives):

Halon 1011, 1211 or 1301 a liquid gas is filled in extinguishers. It is used in place of CO, extinguishers but is lighter in comparison. 1.5 ,3 and 6 kg cylinders and bigger sizes are available in wheel mounted model. By pressing a knob in cap-assembly it can be started. Nose should be covered to avoid direct inhalation.

It is suitable for class B and C fires. See IS 11108 for Halon 1211.

Halon is a fast extinguishing agent. It is ideal for intense and rapid fires. It is non-conductive and leaves no traces when applied. Therefore it is also suitable for electrical fires, computer rooms etc.

Halon interrupts the chain reaction at the flame zone of fire. It is two times as effective as CO_2 on a weight basis and five times as effective as CO_2 on volume basis.

Halon is stored under pressure in a cylinder. A squeeze grip type nozzle is provided on top of the cylinder valve depending upon capacity. It is available in 2,4,5,25 and 50 kg capacities. Mostly two types of Halons (halogenated agents) are used as they are less toxic - (1) Halon 1211-Bromochloro difluromethane i.e. CF_2BrCI and (2) Halon 1301 - Bromotrifluromethane CF_2Br.

5.4.2 Fixed Fire Installations :

Fixed automatic fire installations are desirable from the design stage, as they can be used for longer time and are more effective than the portable type.

(1) Fire Hydrants :

Fire hydrants are economical and should be installed freely around the plant. They should be kept accessible, unobstructed and protected for safety. Indicator posts are advisable.

Fire hydrants, hoses, nozzles and couplers are part of the system. Fixed nozzles are single or double headed. Monitor nozzles are on swivel joint and can be turned as desired and to clear any obstruction. Hose nozzles can be extended and laid (i.e. more flexible) wherever required. They are of fixed flow type, adjustable flow (variable discharge) type and a combination type.

The number of hydrants needed depends on the fire exposure and the hose-laying distance to the built-up areas. The discharge ports should be at least 18 inch (45 cm) above the ground level.

Fire Hose and Nozzles of standard size, double jacketed rubber-lined should be stored in hose boxes and should be subjected to a full pressure test once a year. Space around hose lines and control valves should be clear. Aisles and door ways should be wide enough and clear to allow rapid use of hose reel cart or mobile equipment.

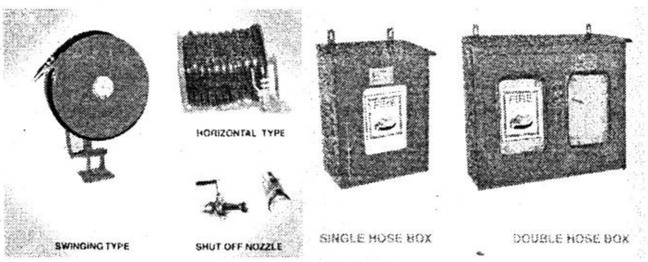


Fig. 13.5 Hoze reel, Hoze Box and Nozzle.

Monitor Nozzles are used in yards and large congested areas where it is difficult to lay hose line in an emergency. The nozzle is so positioned to direct a high pressure water stream over desired area and height.

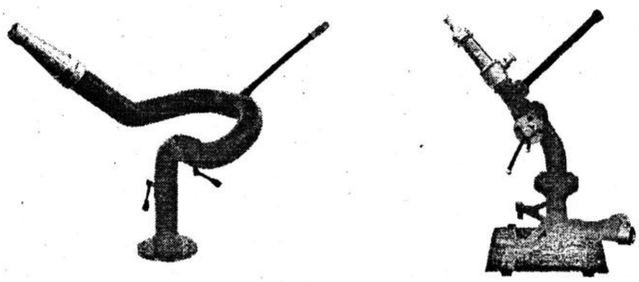

Fig. 13.6 Fixed monitor & Portable Ground Monitor

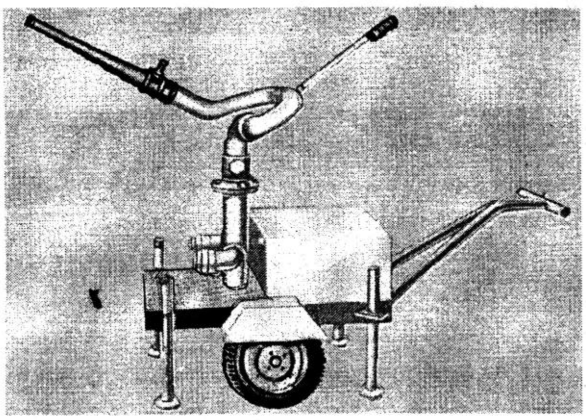

Fig. 13.7 Trolly mounted water monitor.

Water Reservoirs are necessary for the supply of fire water at good pressure and volume. They should not be used for other purposes such as process requirement. If the reservoir is common, suction pipe (its bottom end) for process water should be at a higher level than the suction pipe for fire water into the bottom of the reservoir to maintain the level of reserved water for fire protection.

Water Supply from reliable sources is essential. Reservoirs, overhead tanks, pressure tanks, pumps, pipes and connections must be maintained well. Flow discharge may vary from 10 to 40 litres per second and pressure from 7 to 10 kg./cm2.

TAC guidelines(rules) for water supply for hydrants are as under :

Water for the hydrant service shall be stored in any easily accessible surface or underground lined reservoir or above ground tanks of steel, concrete or masonry. The effective capacity of the reservoir(above the level of the foot valve seat in case of negative suction and above the level of the top of the pump casing in case of positive suction) for the various classes of occupancies (as per rule 7.2) and size of hydrant installations shall be as indicated in Table 13.6 hereunder:

Note 1: Reservoirs of and over 2,25,000 litres capacity shall be in two interconnected compartments to facilitate cleaning and repairs.

Note 2: Large natural reservoirs having water capacity exceeding ten times the aggregate water requirements of all the fire pump drawing there from may be left unlined.

Table 13.6 : Capacity of water storage

Nature of Risk	Capacity of static storage exclusively reserved for hydrant service.
1. Light Hazard	Not less than 1 hour’s aggregate pumping capacity with a minimum of 1,35,000 litres.
2. Ordinary Hazard	Not less than 2 hour’s aggregate pumping capacity.
3. High Hazard (A)	Not less than 3 hours’ aggregate pumping capacity.
4. High Hazard (B)	Not less than 4 hours’ aggregate pumping capacity.

Note 1 : The capacity of the reservoir for Ordinary and High Hazard Class Occupancies may, at the discretion of the Committee, be reduced by 2 hours' inflow from a reliable source (other than a town's main) but in no case shall the reservoir capacity be less than 60% of that mentioned above.

Note 2 : In case of Light Hazard Class Occupancies the minimum capacity of the reservoir shall be increased to 2,25,000 litres if the highest floor of the building is more than 15 mt above the surroundings ground level.

The capacity for hydrant service shall be determined by the class of occupancy and size of installation as per Table 13.7.

Table 13.7: Pump, Capacity and Delivery Pressure :

Sr. No.	Nature of Risk	Number of Hydrants	Pump Capacity in Litres / Sec (m^3/ hour)	Delivery pressure at rated capacity kg/cm2
1	Light hazard	i) Not exceeding 20 ii) Exceeding 20 but not exceeding 55 iii) Exceeding 55 but not exceeding 100 iv) Exceeding 100	27 (96) 38 (137) 47 (171) 47 (171) plus 47 (171) for every additional 125 hydrants or part thereof.	5.6 7 7 7/8.8
Note : The total pumping capacity need not be greater than 190 (683) irrespective of the number of hydrant points.				
2	Ordinary Hazard	i) Not exceeding 20 ii) Exceeding 20 but not exceeding 55 iii) Exceeding 55 but not exceeding 100 iv) Exceeding 100	38 (137) 47 (171) 76 (273) 76 (273) plus 76 (273) for every additional 125 hydrants or part thereof.	7 7 7 7/8.8
Note : The total pumping capacity need not be greater than 302 (1092) irrespective of the number of hydrant points.				
3.	High Hazard (A)	i) Not exceeding 20 ii) Exceeding 20 but not exceeding 55 iii) Exceeding 55 but not exceeding 100 iv) Exceeding 100	47 (171) 76 (273) 114(410) 114(410) 114(410) for every additional 150 hydrants or part thereof.	7 7/8.8 7/8.8 7/8.8/10.5
4	High Hazard (B)	i) Not exceeding 20 ii) Exceeding 20 but not exceeding 55	Two of 47 (171) Two of 76 (273)	7 7/8.8

		iii) Exceeding 55 but not exceeding 100 iv) Exceeding 100	Two of 114(410) Two of 114(410) plus one of 114(410) for every additional 200 hydrants or part thereof.	7/8.8 7/8.8/10.5

This provision will apply only in cases where the hydrant service has been hydraulically designed as per NB 3(13) u/r 7.5.10.

Note: In case of Light Hazard Occupancies, the pump delivery pressure will need to be 7 kg/ cm2 if the highest floor of the risk is at a height exceeding 15 mt above the surrounding ground level:

Proper drainage facility shall be provided to drain the fire-fighting water out of the basement.

Storage of material in the open shall be protected as under:

Metals, Metallic goods, Machinery and goods, Machinery and other non-hazardous storage.	One single hydrant for every 60m. of the storage periphery located beyond 2 m., but within 15 m. of storage area.
Coal or Coke	One single hydrant for every 45m. of the storage periphery located beyond 2 m., but within 15m. of storage area.
Other storage	One double hydrant for every 45 m. of the storage periphery located beyond 2 m., but within 22.5m. of storage area.

Note 1: In case of open storage areas of following materials, at least 50% of hydrants shall be replaced by fixed monitors having nozzle bore of 38 mm diameter if the individual stack height is more than 6 m. and total storage exceeds 5000 tonnes.

Bamboo Bagasse.
Grass/Hay Timber.

Note 2: Where hydrants/monitors located along one longer side of a storage area are more than 90 m. from those along the other longer side, such a storage area shall not be deemed to be protected.

Protection for combustible/flammable liquid Storage Tanks:

Tank less than 20 m. in diameter.	One double headed preferably two single headed hydrants located beyond 15 m., but within 35m. of tank shell.
Tanks over 20 m. in diameter.	Two double headed or four single headed hydrants located beyond 15 m. but within 35 m. of tank shell.

Note 1: In case tanks are located more than 22.5 m. from the dyke walls, one double hydrant or two single hydrants shall be replaced by a 38 mm monitor.

Note 2 : Where the distance of tank from the monitor exceeds 45 m. in addition to provisions of Note I, the tank shall be protected by Fixed Foam or Medium Velocity Water Spray System having prior approval of the Committee.

Note 3 : Hydrants/Monitors shall not be installed within dyked enclosures nor can the hydrant main pass through it.

Note 4 : Fixed roof type storage tanks, floating roof type storage tanks exceeding 30 m. in diameter and Bullets/Spheres containing products having flashpoint below 32 °C shall be protected by Medium Velocity Water Spray System conforming to relevant regulations.

However, manually-operated systems shall also be acceptable.

Water spray systems shall not be insisted for Insulated Vessels/Spheres."

"Water spray protection for small size tanks up to 10 mtr. diameters in ordinary and high hazard risks shall not be insisted upon."

(2) Automatic Water Sprinklers :

They are of six types. Wet pipe, dry pipe, pre-action, deluge, combined dry pipe and pre-action and sprinklers for limited water supply system. Automatic alarms operated by the flow of water should be a part of sprinkler installation. Such an alarm may be connected to a central fire station. The sprinklers should be regularly checked to avoid their failure to work.

Automatic sprinklers are most efficient and widely used. It reduces insurance premium considerably.

Its basic function is to spray water automatically to a fire, the system can also work as a fire alarm. This can be done by installing an electrical water flow alarm switch in each main riser pipe.

Sprinklers should be selected on the basis of temperature rating and occupancy. Their types are Either heat-element or chemical melts or expands to open the sprinkler. Normal detector setting is 68 °C. Sprinklers heads normally cover 12 m3 per head. Amount of water required depends on risk protected, flow range being 0.04 to 0.514 I/m'

In deluge system, water is admitted to sprinklers that are open at all times. Deluge valves (water supply valves) can be operated manually or automatically by an automatic detection system.

Maintenance and inspection of water supply valves, system piping for obstruction, nozzles and water supply tests etc. are necessary.

(3) Water Spray System :

Water spray system uses water in small droplets through special nozzles giving various pressures. The system is supplemented to and not a replacement for automatic sprinklers. It should be checked that the water should not be reactive with the material burning.

The system is similar to the deluge system except that the open sprinklers are replaced by spray nozzles. The system is generally applied to flammable liquid and gas tanks, piping and equipment, electrical equipment such as oil filled transformers, switches and motors. To avoid short circuit, current should be cut off before applying tile spray.

The spray nozzle holes are smaller than those in ordinary sprinklers, therefore they can be choked. To avoid this, strainers (filter or screen) are required in water supply lines. The nozzles having the smallest holes, have their own internal strainer in addition to the supply line strainer.

TAC guidelines on Water Spray Systems give retailed rules. Some extract is given below:

Definitions and terminology relating to the components of the water spray systems are as follows:

(a) **Water Spray System :** A special fixed pipe system connected to a reliable source of fire protection water supply and equipped with water spray nozzles for specific water discharge and distribution over the surface or area to be protected. The piping system is connected to the water supply through an automatically actuated Deluge Valve which initiates flow of water. Automatic actuation is achieved by operation of automatic detecting equipment installed along with water spray nozzles. There are two types of systems namely High Velocity and Medium Velocity systems. The former is useful for liquids with flash point above 65 °C and the latter for flash point below 65 °C.

(b) **Spray Nozzle and Valves :** A normally open water discharging device which, when supplied with water under pressure will distribute the water in a special directional pattern peculiar to the 'particular device. Nozzles used for High Velocity Water Spray systems are called "Projectors" and nozzles used for Medium Velocity Water Spray systems are called "Sprayers". Both these nozzles are made in a range of orifice sizes with varying discharge angles so that discharge can be controlled for optimum protection.

Different types of valves are used with fire water piping system or water hydrants as shown in fig. 13.8.

(c) **Deluge Valve :** A quick opening valve which admits water automatically to a system of projectors or sprayers and is operated by a system of detectors and/ or sprinklers installed in the same areas as nozzles.

(d) **Control of Burning :** Application of water spray to equipment or areas where a fire may occur to control the rate of burning and thereby limit the heat release from a fire until the fuel can be eliminated or extinguishment effected.

(e) **Exposure Protection :** Application of water spray to structures or equipment to limit absorption of heat to a level which will minimise damage and prevent failure whether source of heat is external or internal.

(f) **Impingement:** The striking of a protected surface by water droplets issuing directly from projectors and/or sprayers.

(g) **Run Down :** The downward travel of water along a surface caused by the momentum of the water or by gravity.

(h) **Slippage :** The horizontal component of the travel of water along the surface beyond the point of contact caused by the momentum of water.

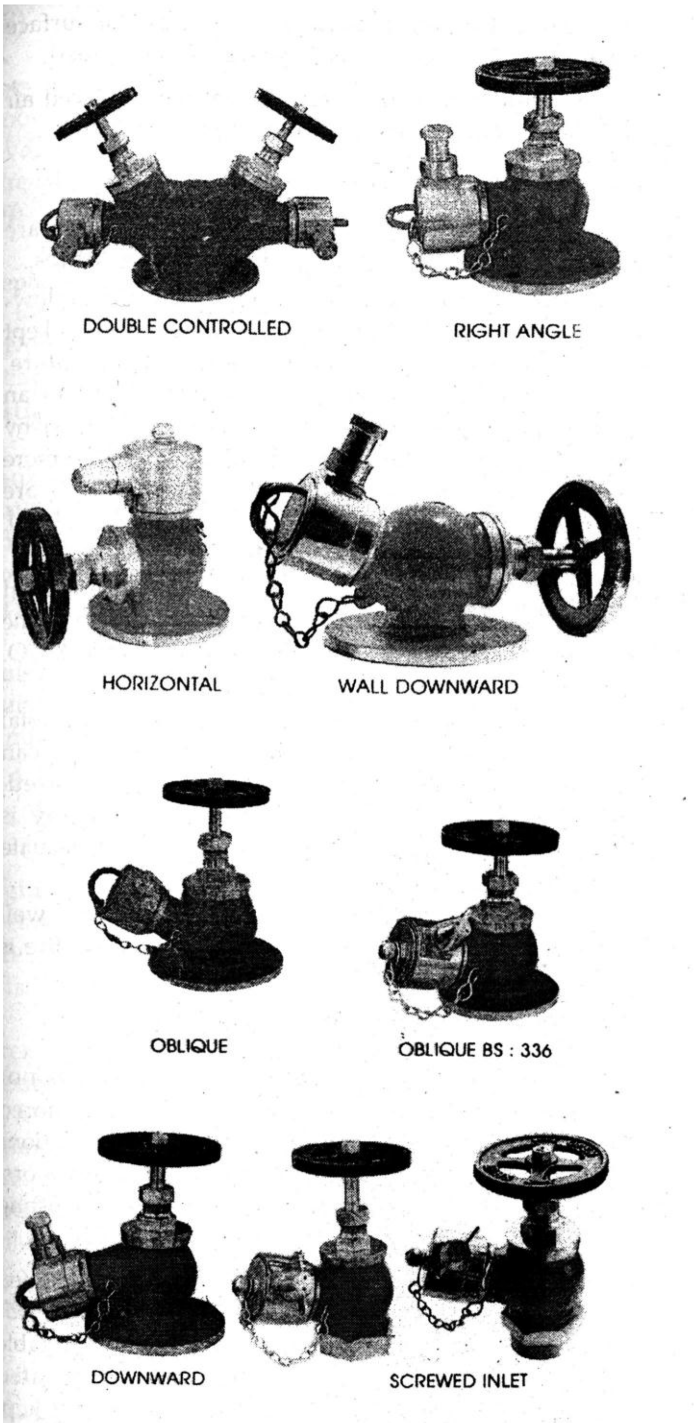

Fig. 13.8 Types of valves.

(i) Insulated Equipment : Equipment, structure vessels provided with insulation which for the expected duration of exposure, will protect steel from exceeding a temperature of 454 "C (850 °F) for structural members and 343 °C (650 °F) for vessels.

(j) Density : The unit rate of water application to an area or surface expressed in litres/min/ m

(k) Automatic Detection Equipment : Equipment which will automatically detect one or more components directly related to combustion such a heat. Smoke, flame and other phenomenon and automatic actuation of alarm and protection equipment.

(i) **Fire Barrier :** It is a continuous wall or floor that is designed and constructed to limit the spread of fire.

(m) **Range Pipes :** Pipes on which sprinklers are attached either directly or through short arm pipes which do not exceed 30 cm in length.

(') **Distribution Pipes :** Pipes which directly feed the range pipes.

Testing and maintenance of water spray system is given m Table 13.8.

Table 13.8 Periodical Testing and Maintenance Chart

Sr	Subject	Activities	Duration
1	Reservoir	Level checking	Weekly
		Clearing	One in 2 years
2	Pump	Running test	Daily
		Test flow	5 minutes
		Lubrication	Annually
		Gland	Quarterly
		Packing	Weekly
		Overhaul	One in 2 years
3	Engine	Running	Once in day (5 mins)
		Fuel tank check	Daily
		Lubrication	Quarterly
		Battery status	Weekly
		Load test	Annually
		Overhaul	Once in 2 years
4	Motor	Lubrication	Weekly
		Starter contact checking	Weekly
		Insulation resistance check	Half yearly
5	Main piping	Gauge pressure	Check daily
		Flushing	Once in 2 years
6	Sluice valves	Operation	Monthly
		Gland packing	Monthly
		Lubrication	Quarterly
7	Deluge valves	Operation	Weekly
		Alarm check	Weekly
		Cleaning	Quarterly
		Overhaul	Annually
8	Sprayers	Cleaning	Quarterly
		Flow test	Quarterly
9	Detectors	Performance	Six monthly
10	Spray installation	Performance	Quarterly
		Physical check up of piping for seeing dislocation of support, wrong orientation overloading etc.	Monthly
11	Pressure gauges	Calibration	Annually
12	Painting of entire installation		Every 2 years

(4) **Foam System :**

It uses fixed foam apparatus either automatic or manual. It may consist of one or more portable foam extinguishers suspended in such a way that flame or heat releases a cord or fusible link to operate the extinguisher automatically. Discharge rate may vary from 15 to 4000 gpm. Foams are of two types - chemical and mechanical. Chemical foam is produced by a chemical reaction of CCX, bubbles and a foaming agent. Mechanical foam is created when air and water are mechanically agitated with a foam solution.

Fire fighting foam (gas-filled bubble solution) is lighter than most flammable liquids. Therefore it forms a floating blanket on burning liquid, cuts off oxygen supply and also cools the fuel.

Foam system is generally used to protect fuel tanks, oil and paint storage rooms, asphalt coating etc. It can be injected on the liquid surface in a tank to provide blanketing effect and to cut off flames and vapours.

Foam is of two types - Low expansion and High expansion foam. Low expansion foam is of four types Chemical foam, Mechanical -or air-generated foam, Protein foam and Synthetic (fluorinated surface active agent) foam. Foam generators of different types are available.

Foam-water sprinkler and spray systems use mechanical foam equipment with a deluge sprinkler system.

High-expansion foam is best suited for class A and B fires in confined spaces such as sewers, basement. It is made by mixing a small amount (@ 1.5%) of foam liquid into a foam generator where water and large quantities of air are mixed. Accumulated foam can act as an insulating barrier for the surface not involved in fire. Thus it prevents fire spread.

Ventilation is necessary to vent the displaced air and gases when foam is being applied.

(5) Carbon dioxide systems :

These are fixed, local or flood type. They are generally useful for electrical, liquid and gas fires.

CO_2 system may be of high-pressure or low pressure type. In the high pressure system, CO_2 is kept in a compressed gas cylinder at normal temperature, while in the low pressure system, it is stored in an insulated pressure vessel at —18 °C and 300 psi by mechanical refrigeration. At such low temperature more CO_2, can be stored economically. Safety valves are provided to take care of refrigeration failure. Liquid CO_2 can bedelivered through nozzles at 15 kg/sec.

In both the systems, CO_2 can be released manually or automatically through nozzles close to the expected source of fire. Unlike water or chemical, CO_2 does not spoil the stock or equipment.

In a room, compartment or small building, total flood system can be used where wall openings can automatically be shut when the gas is released. Warning alarm to alert people working nearby is necessary. Sufficient time must be allowed to evacuate the area.

In a confined place, the area should be well ventilated and checked for 0, content after the fire is extinguished.

(6) Dry Chemical Powder (DCP)

Dry Chemical Powder is neither toxic nor conductor of electricity, nor does it freeze. It is stored in an inert gas cylinder under pressure. Installations can be provided for simultaneous closing of fire doors, windows, ventilating ducts, operating valves, shutting off fans and machinery and actuating alarms.

The dry chemical piped systems are developed for fast extinguishment in a confined area or for localised application. They are useful on flammable liquid and electrical hazards and can be operated manually, automatically or remotely. The agent is kept in a pressurised container fixed or mounted on vehicles.

Action of extinguishment is to interrupt the chain reaction of fire by the dry chemical agent.

Dry chemicals include Sodium bicarbonate as standard dry chemical. Potassium bicarbonate. General purpose powder (ABC) and Monnex powder. If electrical equipment is not involved, foam can be used to follow DCP application.

(7) Vaporising Liquid system :

It uses carbon tetrachloride, methyl bromide or chlorobromo methane as an extinguishing agent. All these being toxic, care in handling (with PPE) is essential.

(8) Steam System :

It uses automatic or manually controlled steam jets to smoother fire in closed containers or small rooms. It is practicable where continuous steam is available. It is not effective on deep-seated fires. precautions against burns should be followed.

(9) Inert Gas System :

It uses CO_2, N_2, flue gas or other inert gas to replace O_2, in air. Oxygen should be reduced between 5 to 16%, depending upon the combustible material involved. After the use, the place should be thoroughly ventilated and tested for normal oxygen for re-entry.

(10) Air Agitation :

It uses air or other gas injection to induce in the tank or container an upward flow from the colder (bottom) surface to the burning (upper) surface, thereby cooling the surface. Generally this system is useful for small oil fires in tank or container.

(11) Drenchers :

Drenchers in roof, wall or window throw water outside the building to protect it from fires coming from outside. A drencher system is made up of water heads similar to sprinklers.

5.4.3 Automatic Fire Detection and Extinguishing System:

This system is the latest development in fire fighting techniques in European countries. With fire trace trade name it is used to detect and extinguish fire directly at the source automatically, quickly and efficiently.

It can be used at any type of fire risk. Its pressurised flexi-tube delivery system is leak resistant, flexible, temperature sensitive and rupturing at 100 °C to form a distribution nozzle that delivers pressurised extinguishing media (foam) directly on the source of fire. It is a self contained stand alone system. Its operation is not affected by power or water main failures. It reacts reliably every time.

This system is of two types, direct release system and indirect release system.

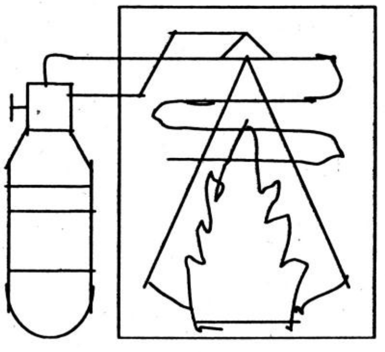

Fig 13. Direct Release System

In a Direct Release System the same tube is utilised for both the detection device and extinguishing delivery system. The portion of the tube nearest the hottest point of the fire ruptures at 100 °C forming an effective spray nozzle. The pressure drop in the tube releases the entire contents of the cylinder through the distribution nozzle to extinguish the fire. More tubes can be used to cover more area.

In Indirect Release System the detection tube ruptures at 100 °C and the resulting pressure drop causes the indirect valve to activate diverting flow from the detection tube to the larger outlet ports.

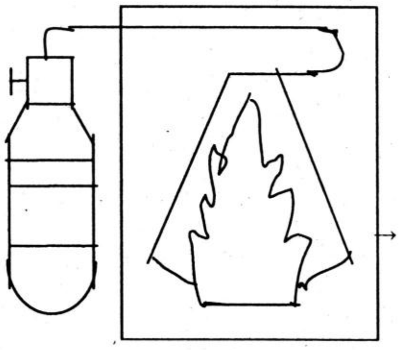

Fig 13. Indirect Release System

Extinguishing agent is then discharged from the cylinder through the diffuser nozzles flooding the area to extinguish the fire quickly. This system is more useful for larger area.

The extinguishing agents tested and used in Fire trace systems include : water, powder, foam, CEA410, FM200, every Halon replacement up to 40 bar working pressure and CO,.

Advantages: This system offers many advantages against conventional fire extinguishing systems as under:

1. Automatic detection and suppression of fire.
2. Extinguishing media is site-specific and minimises damage. It includes water, foam, DCP or clean gas.
3. Flexible, narrow tubing can be inserted into confined spaces.
4. No electricity required. It can work even in electrical failure.
5. Simple design reduces maintenance.
6. Always activates at the hottest point of fire.

7. Quick and simple installation. It can be installed anywhere, even at hard to reach places.
8. Cost effective and practical against other extinguishing systems.
9. Performance unaffected by humidity or air flow.

5.5 Control of Fire and Explosion in Flammable Substances :

Fire or explosion in flammable substance is possible only when it leaks and forms vapour in explosive range. Therefore the first step necessary is to regularly check the tank, container, piping, equipment etc. for leakage and to stop it.

Depending on the vapour density, ventilation should be provided at bottom or upper Jevel to remove accumulation of flammable vapour. If because of heating or cooling, the vapour density is changeable, the ventilation/exhaust system should be designed for operating conditions and not for MSDS value.

Natural ventilation openings can be provided near floor, near ceiling or both. Local exhaust ventilation with explosion-proof .electrical equipment is the best measure.

Un-burnt gases or flammable vapour in combustion chambers of heater, ovens, boilers, furnaces may form an explosive mixture. Therefore in the event of flame failure, proper venting or purging time should be allowed or a timed precognition purge cycle should be followed.

A gas detector can be used to check explosive range in the suspected area.

Gas valves and joints should be frequently checked for leaks. If gas is present, ventilation should be allowed before restarting.

Source of ignition is another contributory factor for fire or explosion. Use of flame/smoke detector, flameproof electric equipment, proper earthing to discharge static electricity, checking of spark or heat generating processes and their control, hot work permit etc. are the remedial measures.

5.6 Fighting Fires of Pesticides :

Pesticides when bum emit toxic fumes and when dissolve in fire water; it cannot be allowed to run anywhere as its contact will become poisonous and birds and animals may die if they drink it. Effect depends upon its toxicity and concentration in air or water. Hazard is also faced by the fire fighters, and the people in vicinity. Therefore utmost care is required while fighting fire of pesticides.

Design of pesticide storage is most important in this regard. Fire detectors and automatic sprinklers should work avoiding human need. Water inside must flow on well designed slope to go to retention basin and from there to the specific collection pond or tank to collect polluted water. Such pond/tank should have proper fencing to keep away people and animals. After the control of fire, this contaminated water must be treated for safe discharge.

If fire takes place in open, persons fighting fire should wear self breathing apparatus, should not face the wind direction, feet, hands and body should be protected, water should be safely diverted to a safe place and covered by sand, lime or any inactivating media.

In case of solvent based liquid pesticide, foam and DCP may be more useful.

Other precautions include prohibition of smoking, keeping flammable pesticide away from sun, heat and source of ignition, keeping people away from risk, calling help if needed and cleaning up area and clothing after extinguishing the fire. Medical attention and treatment without loss of time are necessary if any person is adversely affected.

5.7 Electrical Fires:

Water cannot be used to extinguish electrical fire till it is energised i.e. the circuit is live. If it is possible to put off electrical power supply and to de-energise the electrical circuit, equipment or wire caught in fire, it must be done first. Then this fire can be extinguished as class-A or B fire as stated in Table 13.4 Then water or soda acid type, foam or DCP type and CO or Halon type, any extinguisher can be used.

If it is not possible to put off electricity (de energising not possible), it should be treated as class-E fire and Carbon dioxide or DCP type extinguishers should be used. Sand buckets are also useful.

For a room or enclosure covering electric motors, cables, equipments etc, automatic fire detection and CO injection system are available. In electric power plants such systems are more useful to fight electric fires and to save costly machinery.

Rule 66-A (13) (4) of GFR prescribes following statutory provisions where electrical fires are anticipated

1. Where electrical transformers, switchgears motors and/or electrical apparatus are contained in a room, at least two DCP or CO extinguishers (cap = 2kg) shall be provided within 15m distance from that room.
2. In other rooms where motors and/or other electrical machinery are there, at least one DCP or CO, extinguisher (cap = 5 kg) will be provided within 15 m. distance from such room.
3. Where electric motors are installed on platform, one DCP or co, extinguisher (cap = 2 kg) shall be provided for 3 motors on or below the platform.

This is in adding to the general requirements stated in the rule (66-A).

Thus fighting of electrical fires requires special precaution and provision as stated above. .

5.8 Effects of Combustion Products :

As stated in part 1.3.2 earlier, due to incomplete or complete combustion, following gases are produced and their effects should be controlled as under –

Combustion products (effects) due to fire		Control measures required
1	Free radicals to maintain chain reaction.	DCP or Helogen content extinguishers.
2	Smoke due to incomplete combustion	Make the combustion complete. Supply more air. Remove blockage from air path. Provide smoke escape windows or passage.
3	Heat due to exothermic reaction	Water curtain or shield for protection from radiant heat.
4	Water vapour	Allow to escape safely.
5	CO	Proper respirator for this toxic gas. Increase oxidation CO detector with alarm on furnaces
6	CO_2	Allow to escape safely.

7	SO_2	Allow to escape safely. Use tall chimney or flare etc
8	Gases depending on type of burning chemical (e.g. Toxic gases from pesticide burning etc)	Use appropriate respirator or gas mask to fight such fire. See Part 5.5 & 5.6 for specific fires.

Combustion products should be assumed or detected for its safe control.

5.9 Fire Emergency Action Plan and Drill:

Fire emergency action plan should be similar to 'On-Site Emergency Plan' explained in chapter-19. Here type of emergency is a fire or explosion emergency. Key elements of such plan are as under :

1. Assess all possible fire emergencies or the maximum foreseeable loss (MFL) factor. Mark fire/explosion prone areas on the factory plan.
2. Assess resources (men, material, equipment etc.) available in the plant and make a list of them with their locations, contact phones and incharge persons. See fig. 13.9.
3. Assess resources needed from outside and make a list of them with their places of availability, contact persons and phone numbers.
4. Prepare a central control room for co-ordination of emergency time activities.
5. Prepare an organised group of key persons who will act to control the emergency. Site Main Controller, Incident Controller and other responsibilities should be decided. Everybody should be given their role in writing. Table top exercise and rehearsal will be carried out to shape their actions.
6. All communication systems shall be maintained in workable order. New system shell 663e procured if necessary.
7. Double gates (one for entry, one for exit), unobstructed inner roads and proper sign boards shall be displayed.
8. Housekeeping shall be regularly checked. Accumulation of rubbish and combustibles shall be removed soon.
9. Fire water, working order of fixed fire installations and placement of charged portable extinguishers shall be regularly checked.
10. Alternate power source shall be kept ready.
11. Runners shall be arranged to act in the event of communication failure.
12. Distinctive garments or cap, band etc. shall be given to emergency controllers.
13. Decide assembly points for safe gathering by other people.
14. Keep arrangement for medical, security and transport in readiness to handle the -emergency.
15. Train fire fighting crew, medical staff and other workers for their emergency time and post emergency time activities.
16. It should be assured before restarting the normal work that fire is fully extinguished, environment is cooled, debris etc. removed, all-clear signal is given and the plant is ready for restart.

Fig. 13.9 Fire Tander & Ambulance van to be used in emergency.

Fig. 13.10 Fire fighting with floating pump.

Assessment of probable scenarios and Drill:

Fig. 13.10 Fire fighting with floating pump.

Flammable materials and their processes must be identified first. Based on these flammable materials, their quantities, storage parameters and flammable processes, probable scenarios should be decided and listed in the fire emergency action plan. In periodical fire drill, different scenarios should be selected at different times from the above list. This will help to

train our plant personnel to fight with all types of fire. Necessary PPE should be used while participating in such drills. Scenario of fighting fire with floating pump can also be a part of drill as shown in fig. 13.10.

Fire control room should be well established. Audio visual indication should be available by fire call bells. Fast communication and public address system should be provided. Trained staff should be available. Necessary documents including lists of telephone numbers and mutual help contact persons should be readily available in the control room. It is desirable to conduct at least one fire drill in one quarter or statutory periodicity should be followed.

6 EXPLOSION PHENOMENA :

Before understanding types or forms of explosion, it is necessary to understand explosion it self, its cause and nature, types of explosives, explosion hazards etc.

6.1 Explosion :

Explosion is the result of rapid combustion with a sudden, violent change of pressure involving the liberation and expansion of a large volume of gas.

Thus release of energy in a rapid and uncontrolled manner gives rise to explosion. The released energy may appear as heat, light, sound or mechanical shock. Combustible dusts or powders, flammable vapours and flammable gases can explode. A combustible material, air and source of ignition (or temperature) are the prerequisites for an explosion.

Thus explosion is a sudden and violent release of energy. Its effect depends on the rate at which the energy is released.

Difference between fire and explosion is the rate of release of energy. in fire it is at high rate and in explosion it is at high rate and sudden release.

Three types of energy can be released : physical, chemical or nuclear. Bursting of tyre, vessel, pipe etc. due to overpressure or brittle fracture and flushing of superheated liquid (thermal energy) are examples of physical energy. Chemical energy is released due to chemical reaction. If may be uniform as in case of a vessel, or it may be propagating as in case of a long pipe. Exothermic or runway reaction, decomposition and polymerisation are also examples of chemical explosion. Nuclear energy release can cause nuclear explosion.

Types of explosion are deflagration and detonation. It is also classified as confined and unconfined explosion, BLEVE, gas and dust explosion. See Part 6.2.

Explosion Data refers information on the explosive properties of a material and is usually given in descriptive terms, such as low, moderate or high.

Explosion hazard of a material can be described by its:

1. Sensitivity to mechanical shock or impact, which indicates whether or not the material will burn or explode on shock or friction and
2. Sensitivity to static discharge, which indicates how readily the material can be ignited by an electric shock.

Explosion hazards in process plants are of many types. They include (1) Dust explosions (2) Molten Metal water explosions (e.g. induction furnace) (3) Air system explosions (4) Superheated liquid explosions (5) Mist and Spray explosions and (6) Crankcase explosions.

Explosive limits specify the concern fraction range of a material in air (percentage volume) which will burn or explode in the presence of an ignition source. Explosive limits of some common chemicals are as under:

Chemical	LEL (%)	UEL (%)
Acetylene	3	82
Benzene	1.4	8
Butadiene	2	11.5
Butane	1.9	8.5
Carbon disulphide	1	44
Hydrogen	4	75
Methane	5	15
Natural gas	3.8	17

For other chemicals see MSDS for such explosive limits.

Explosive material is classified as high, low and initiating as under :

High explosive is a chemical compound usually containing nitrogen that detonates as a result of shock or heat. Examples of high explosives are dynamite, ammonium nitrate slurries sensitised with TNT, acetylides of copper and silver, nitroglycerin, mercury fulminate.

Low explosive deflagrates rather than detonates, such as black powder.

Initiating explosive is an explosive composition used as a component of blasting caps, detonators and primers. They are highly sensitive to flame, heat, impact or friction. Examples are lead azide, silver acetylide, mercury fulminate, diazodinitrophenol, nitrosoguanidme, lead styphnate and pentaerythritol tetrardtrate.

In an explosion caused by a high explosive, the rate of energy release is rapid and the explosion has high shattering power. The shock wave from such explosion has a very short duration time.

Sources of ignition that may cause explosion are (1) Sparks (2) Flames and hot surfaces (3) Static electricity (4) Compression and (5) Chemicals-pyrophoric material, unstable compounds, reactive compounds arid catalysts.

Effects of explosion are more relevant to safety problems. They include (1) Blast damage-primary and secondary (2) Missile damage (3) Thermal effects (4) Ground shock (5) Crater and (6) Effects on people.

Shock wave is a pressure wave moving through a gas. A shock wave in open air and combined with wind wave is called 'blast wave'.

Shock-waves due to explosion can cause damage to buildings breaking windows and ejecting missiles over distances of several hundred metres. People can be blown over or knocked down, buried under collapsed material or injured by flying fragments. People in the vicinity of over-pressure may die and injuries due to indirect effects are also serious.

The effects of explosion depend on nature and quantity of material involved and the degree of confinement of the vapour cloud. The pressure decreases rapidly with increase in distance. For example the explosion of a tank containing 50 tonnes of propane results in a pressure of 14 kPa at 250 mt and a pressure of 5 kPa at 500 mt from the tank.

At a pressure of 5 to 10 kPa, people can be injured, while structural demolition and doors/ windows breaking is possible at a pressure of 3 to 10 kPa.

Data on fatality is given by Glasstone as under :

Probability of fatality (%)	**Peak overpressure (psi)* (Duration 400 milliseconds)**
1	35-45
50	45-55
99	55-65

*** Overpressure** = above the atmospheric pressure.

Explosion pressure on an object is as a result of an impacting shock wave.

Much higher overpressures are required to effect the same levels of fatality for the durations of the order of 1-15 milliseconds typical of high explosives.

Data on eardrum rupture due to direct blast effect is given by Eisenberg as under:

Probability of eardrum rupture (%)	Peak overpressure (psi)
1 (threshold)	2.4
10	2.8
50	6.3
90	12.2

Extent of injury (laceration, wound etc.) depends on the weight of a flying fragment (g), its density (g/ CM2), peak pressure (psi)and impact velocity (m/s). Based on these factors, Eisenberg considered a flying glass fragment of lOg .with 2.65 g/cm' density and gave following data :

Type of injury	Peack pressure (psi)	Impact velocity (m/s)
Skin laceration threshold	1-2	15
Serious wound threshold	2-3	30
Serious wound 50% probability	4-5	55
Serious wound 100% probability	7-8	90

Table 13.9 gives some historical figures on explosion events.

Table 13.9 Examples of explosion events.

Year	Place	Chemical	Deaths	Injuries
1921	Oppau, Germany	Ammonium nitrate	430	-
1942	Tessenderloo, Belgium	Ammonium nitrate	100	-
1947	Texas City, US	Ammonium nitrate	552	3000
1948	Ludwigsha fen, W. Germany	Dimethylether	245	3800
1954	Bitburg, Germany	Kerosene	32	16
1967	Lake Charles	Isobutene	7	13
1972	East St. Louis, Illinois, US	Propylene	-	230
1974	Decatur, Illinois, US	Propane	7	152
1974	Flixboroug h, UK	Cyclohexane	28	89
1975	Beak, Netherlands	Propylene	14	107

See also Table 13.1 for fire and explosion events.

Explosion Control Devices :

Main methods to prevent any type of explosion are (1) Avoidance of flammable mixture by good ventilation, dilution, dust collection system, wet methods etc. (2) Avoidance of sources of ignition by avoiding excessive heating (temperature), elimination of spark, flame etc., using spark/flame arrester, using explosion proof electrical equipment and fittings and by avoidance of static electricity, avoiding friction etc.

Explosion Protection and Relief includes the methods of (1) Flame arresters and avoidance of source of ignition. (2) Automatic isolation (3) Automatic suppression (4) Separation (5) Containment (6) Venting of ducts and pipes (7) Venting uF vessels (8) Venting of reactors and (9) Explosion relief of plant and equipment.

Despite all such methods, if explosion is possible, control measures should be adopted such as to limit the spread and effects of an explosion by providing explosion relief devices such as rupture diaphragms or explosion doors/windows, panels or vents, providing blast-walls or strong enclosure etc.

Explosion venting devices:

Explosion venting is the most widely accepted and utilised explosion protection strategy in use today. Various types of devices are used to provide explosion overpressure protection, such as certified rupture panels (explosion vents), hinged devices, shear type fasteners, home made (uncertified) venting panels, "blow out panels" etc. Many of these devices offer some redeeming benefits, but in the end are not reliable as explosion protection options.

In view of the reduced efficiency, hinged enclosures and light-weight rupture diaphragms are recommended.

For explosion venting device, there are five important performance characteristics to consider:

1. Venting Efficiency - Efficient devices require less relief area and/or provide lower vented pressures.
2. Certified Burst Pressure (P) -The venting device tested and warranted to open at the identified pressure every time.
3. Opening Pattern - It provides the expected relief area every time.
4. Fragmentation - Its operation creates dangerous projectiles, therefore less proffered.
5. Reliability - It operates properly when needed.

6.2 Types of Explosion

6.2.1 Dust Explosion

It is possible due to flammable dusts of wood, coal, food(starch, flour, sugar, cocoa, feed stuffs), chemicals, plastics (urea formaldehyde, resin, polyethylene, polystyrene), metals(aluminium, magnesium) etc..

It results from rapid combustion of fine solid particles like iron, aluminium, wood, starch etc. Many solid particles when reduced to fine powder becomes very flammable and explosive.

At a starch/corn plant at Ceder Rapids, Iowa in 1919, 43 people were killed and at Peking, Illinois in 1924, 42 people were killed due to dust explosion.

At a starch plant at Ahmedabad, 29 workers injured and out of them 20 died due to starch dust explosion on 19-12-1991.

Explosion characteristics of dust suspension are as under:

1. Explosibility classification.
2. Minimum explosible concentration.
3. Minimum ignition temperature.
4. Minimum ignition energy.
5. Maximum permissible oxygen concentration to prevent ignition.
6. Explosion pressure characteristics.
   (a) maximum explosion pressure.
   (b) maximum rate of pressure rise.

(c) average rate of pressure rise.

Sources of ignition for dust explosions are (1) Flames, heat or hot surfaces (2) Welding and cutting (3) Mechanical sparks (4) Self-heating (5) Static electricity and (6) Electrical equipment.

Preventive methods for dust explosion include (1) Avoidance of dust suspensions (2) Wet process (3) Elimination of source of ignition and (4) Inserting.

Methods of protection against dust explosion include (1) Isolation (2) Containment (3) Explosion suppression and (4) Explosion venting.

Dust fires can occur in dust deposits and are of two types - flaming and smouldering fires.

6.2.2 Deflagration:

It is an explosion with a resulting shock wave moving at a speed less than the speed of sound in unreacted medium.

Deflagration is vary rapid auto combustion of particles of explosive as a surface phenomenon. It may be initiated by contact of a flame or spark but may be caused by impact or friction. It is a characteristic of low explosives.

Deflagration or detonation is a form of explosion, the former is due to low burning velocity (flame speed as I m/s) while the later is due to high burning velocity (flame speed as 2000-3000 m/s). A detonation generates high pressure and is more destructive than a deflagration. The peak pressure caused by a deflagration in a closed vessel can reach up to 70-80 kPa (8 bar), whereas in case of detonation it easily reaches up to 200 kPa (20 bar).

A deflagration can turn into a detonation while travelling through a long pipe. In that case deflagration velocity exceeds that mentioned above.

6.2.3 Detonation:

It is an explosion with a resulting shock wave' moving at a speed more than the speed of sound in unreacted medium.

Detonation is extremely rapid, self-propagating decomposition of an explosive accompanied by a high pressure-temperature wave that moves at from 10009000 m/sec. It may be initiated by mechanical impact, friction or heat. It is a characteristic of high explosives which varies considerably in their sensitivity to shock, nitro-glycerine being one of the most dangerous in this regard.

Whether a deflagration or detonation takes place depends on the material involved and the conditions under which it occurs. A vapour phase explosion requires some degree of confinement for a detonation to take place.

Detonation of a gas-air mixture is possible directly by a powerful ignition source or by transition from deflagration. Such transition requires a strong acceleration of the flame front. It is possible in pipelines but rarely possible in vessels.

A number of substances are listed which can produce detonation in gas-air mixture. Some corftmonly known substances are :

Acetone	Ethylene
Acetylene	Hydrogen
Benzene	Methane
Chloroform	Methanol
Cyclohexane	Naphthalene
Diethyl ether	Trichloro ethylene

Detonation usually occurs at well below the upper explosive limits. Separate Detonation Limits are available for some substances as under:

Substance	Detonation Limits (%)		Explosive Limits (%)	
	Lower	Upper	LEL	UEL
Acetylene	4.2	50	3	82
Ether	2.8	4.5	1.8	48
Hydrogen	18.3	59	4	75

Though upper detonation limits are normally below upper explosive limits, exceptions have been reported.

6.2.4 Confined and Unconfined Vapour Cloud Explosion (VCE) :

Deflagration and detonation discussed in previous part are confined explosions, as they occur in a process vessel, building or pipe work i.e. in a confined space. The only conditions necessary are that the gas mixture Should be within explosive/detonable range and there should be a source of ignition or the mixture should have been heated to its auto ignition temperature . Transition from deflagration to detonation (mostly in pipeline) is also possible.

An unconfined vapour cloud explosion (UVCE) occurs in open at a distance from the point of vapour release and threatens a larger area. A large release of flammable vapours and cloud formation explodes when spark or friction is available. Though it is a rare possibility but has more potential to damage.

A confined vapour cloud explosion (CVCE) occurs in a confined place (e.g. vessel, pipe, building, pit etc.) while UVCE occurs in an open area. The peak pressures of CVCE are much more higher than that of UVCE.

Some examples of UVCE are as under:

Year	Place	Chemical	Qty. (t)	Deaths
1967	Lake Charles, La.	Isobutane	46	7
1968	Pernis, Netherlands	Hydro Carbon	140	2
1970	Port Hudson, Miss	Propane	29	0
1974	Flixborough, UK	Cyclo-hexane	25	28

Data on equipment involved in UVCE name process equipment, storage tank, transportation vehicle and modes of release as vessel failure, piping, valves or fittings failure, release from venting facilities etc.

Some issues connected with confined and unconfined VCF are as under:

1. Determination of detonation limits.

2. Mass of material released and part vaporised.
3. Possibility from deflagration to detonation.
4. Probability of explosion or fire.
5. Probability and technique of ignition of cloud.
6. Dilution due to air entrainment
7. Distance travelled by cloud before ignition.
8. Nature of flame propagation.
9. Types of effects of explosion.

UVCE due to hydrogen are unusual but did occur. Hydrogen venting should be directly to atmosphere via multiple vents or by a flare.

Methane at normal temperature burn but do not explode. Vapour cloud of LNG might explode.

6.2.5 BLEVE :

Boiling liquid expanding vapour explosion (BLEVE), also referred as a fireball, is a combination of fire and explosion with an intense radiant heat emission within a relatively short time interval.

When a tank or pressure vessel containing liquid or liquefied gas above its boiling point (so heated) fails or ruptures, the contents release as a turbulent mixture of liquid and gas, expanding rapidly and dispersing in air as a cloud. When this cloud is ignited, a fireball occurs causing enormous heat radiation intensity within a few seconds. This heat is sufficient to cause severe skin burns and deaths within a few hundred metres depending on the mass of the gas involved. A BLEVE involving a 50- tonne propane tank can cause "third-degree burn at @ 200 mt and blisters at @ 400 mt

Road/rail accident to a tank car/wagon or due to weakening of structure by fire or physical impact on a overstressed vessel/tank can cause a BLEVE.

Some reported major BLEVE examples are as under:

Year	Location	Chemical	Death	Injury
1966	Feyzin, France	LPG (Propane)	18	90
1969	Laurel, Miss	LPG	2	-
1970	Cresent City, III	LPG	0	66
1971	Houston, Tex	Vinyl chloride	1	-
1972	New Jersey	Propylene	2	-
1985	Mexico City	LPG	650	2500

For IS on explosion see part 3.2.

7 INSPECTION, MAINTENANCE AND TRAINING FOR FIRE PROTECTION

IS:2190 suggests that routine maintenance, inspection and testing of all fire extinguishers in respect of their mechanical parts, extinguishing media and expelling means should be carried out by properly trained personnel at frequent intervals but at-least once in a month to make sure that these are in their proper condition and have not been accidentally discharged or lost pressure or suffered damage. Detailed procedure is also mentioned therein.

It is very difficult for a new worker to use any fire extinguisher, to connect a hydrant, to start fire pump, to hold pressurised nozzele, to use fire ladder etc. Training is necessary for handling and operating any fire equipment. Therefore arrangement should be made for regular training and fire drill for all fire fighting staff. Fire Officer should conduct field demonstrations on fire fighting. The training should be for preventive as well as protective techniques. The frequency and nature of training will depend on the size and type of industry. In a refinery or chemical industry it should be more frequent and continuous. Training record should also be maintained.

All fire equipment should be in ready working condition. The defective equipment may prove dangerous in the event of fire. Therefore regular cleaning, lubricating and testing of all fire fighting equipment are most desirable. The defect can be noticed by inspection and testing only. Therefore it should be found beforehand and rectified immediately. Fire pumps - diesel and electrical - should be run everyday for certain time and their performance should be checked and recorded in a log-book. The extinguishers should be recharged as required. Hydrants, monitors, hose reels, nozzles, couplings, foam making equipment etc. should be regularly inspected, tested under pressure and kept in good repair and working condition.

A small inspection checklist is given here which can be expanded as per own requirement.

A Small Checklist for Fire Prevention

Heat and flame: No smoking areas clearly indicated. Ashes kept in metal containers. Gas connections closed when not in use. No gas leaks. Hot pipe clear of combustible materials.

Housekeeping: Premises free of combustible materials. Metal containers for oily rags. Safe. storage of flammable. No leaks and drippings of flammable. No accumulations of rubbish. Passageways clear of obstacles. Necessary fire awarness signs and posters are shown in Fig. 13.11.

Electrical Equipment : No bare wiring or badly worn insulation. Ground connections clean and tight. Fuse and control boxes clean and closed. Motors and tools free of dirt and grease. Explosion proof fittings for flammable areas. No poor joint. No makeshift wiring.

Fire Protection Equipment : In proper place, unobstructed. Clearly marked, in working order.

For fire safety in chemical, textile and engineering industries, read respective chapters.

See Table 13.8 for periodical testing and maintenance chart.

Fig. 13.11 Fire awarness signs and posters.

8 WORKED EXAMPLES :

Fire load calculation:

For the purpose of solving examples, following information needs to be understood.

An important factor in establishing the basis for the assessment of the fire risk pertaining to any building is the concept of 'fire load' which indicates the quantity of heat liberated per unit area when a - building and its contents are completely burnt.

All occupancies/buildings, etc. can be graded according to their fire hazard and are to be provided for with suitable fire precautions on the basis of the fire load.

Hence, grading of buildings according to both, fire load and fire resistance, can be made.

The formula for calculating fire load is as under:

Fire load

$$= \frac{\text{(combustibles in kg) x calorific value in kcal/kg}}{\text{Floor area in square meters}}$$

Fire grading of the structures:

Structural elements of buildings are graded according to the time factor which is nearly equal to but does not exceed the test period which the element fulfills its specified requirements.

Accordingly, all structural elements have been graded under the following five categories depending upon their fire resistance, viz.,

Grade 1......... 6 hours
Grade 2......... 4 hours
Grade 3......... 2 hours
Grade 4......... 1 hours
Grade 5......... 0.5 hours

Occupancies of High fire load:

Godowns, warehouses, etc. This category as per I.S. specifications exceeds the fire load by 550,000 kcal/sq.mtr, but does not exceed an average of 1,100,000 kcal/sq.mtr of floor area. A fire resistance of 4 hours for these types of occupancies is considered sufficient.

(For reference, the maximum for this type in F.P.S. system is 4,00,000 B.Th.U/sq.ft exceeding an average of 2,00,000 B.Th.U/sq.ft).

Occupancies of Moderate fire load:

Retail shops, bazaars, stalls, factories, etc. Here the fire load exceeds 2,75,000 kcal/sq.mtr, and is up to 550,000 kcal/sq.mtr. Occupancies of this type should have a fire resistance of two hours.

Occupancies of Low fire load:

Ordinary buildings for residential purposes, hotels, offices, schools, etc, or occupancies having a fire load not exceeding 2,75,000 kcal/sq.mtr of net floor area of any compartment, nor exceeding an average of 550,000 kcal/sq.mtr on a limited isolated area. (for reference, the maximum for this type in F.P.S. system is 1,00,000 B.Th.U/sq.ft)

The fire resistance required by buildings of this category to withstand the complete burn-out of their. contents without collapse is I hour as has been found after tests. Extensive investigations carried out in Switzerland and Germany have shown that the fire load in offices varies from 10 kg to 30 kg/sq.mtr wood equivalent to 43,356 to 130,068 kcal/sq.mtr. This type of occupancy has an one hour rating with maximum fire loading up to 60 kg/sq.m. equivalent to 270,978 kcal/sq.mtr

Example-1:

A manufacturing process industry uses the following material. Calculate the Fire load by using the following data: -

Material	Quantity in Kg.	Area in Sq. mtr.	Calorific value	
			(kJ/kg)	(Kcal/kg)
Paper	100	100	15600	3725.28
Wood	2000	300	17500	4179
Coal	10000	500	20000	4776
Rubber	500	200	40000	9552
Petroleum product	5000	400	43000	10268.4

1 K Joul = 0.2388 K. Cal

Fire load

$$= \frac{\text{(Combustibles in kg) x Calorific value in kcal/kg}}{\text{Floor area in square meters}}$$

Fire load (paper) = $\frac{100 \times 3725}{100}$ = 3725 kcal/sq.mt

Fire load (wood) = $\frac{2000 \times 4179}{300}$ = 27860 kcal/sq.mt

Fire load (coal) = $\frac{10000 \times 4776}{500}$ = 95520 kcal/sq.mt

Fire load (rubber) = $\frac{500 \times 9552}{200}$ = 23880 kcal/sq.mt

Fire load (petroleum products)
= $\frac{5000 \times 10268}{400}$ = 128350 kcal/sq.mt

Total fire load = 279335 kcal/sq.mt

As this is less than 550000 kcal/sq.mt, as stated above, it indicates low fire load and requires fire resistance of 1 hour.

Installation of fire extinguishers:

Example-2:

Determine the number of fire extinguishers required to give adequate protection for a given property. Risk: Light engineering workshop (Light hazard)

Area: 315m x 112 m.
Type of hazard: Class 'A' fire due to normal combustibles.

As per IS 2190 this is Light hazard. Therefore one 9 ltr. water expelling extinguisher for every 600 sq.mtr of floor area is required.

Extinguisher should be available within 25 mtr. radius..

Here total area = 315m x 112 m. = 35,280 sq. mtr.

No. of extinguishers= $\frac{35,280 \text{ sq.mt}}{600 \text{ sq.mt}}$ = 58.8 = 59

Example-3:

Determine the number of fire extinguishers required to give adequate protection for a given property. Risk: Petroleum processing unit (High hazard) Area: 300m x 150 m. i.e. 45000 sq. mtr. Type of hazard: Class 'B' fire due to petroleum products.

As per IS 2190 this is High hazard. Therefore two 9 ltr foam chemical/mechanical type; or 5 kg capacity dry powder extinguisher for every 600 sq.mtr with minimum of four extinguishers per compartment is required.

Extinguisher should be available within 15 mtr radius.

Here total area is 45000 sq.mt.

Therefore No. of extinguisher = $\frac{45000 \text{ sq.mt .}}{600 \text{ sq.mt}}$ = 75

E X E R C I S E

1. Explain, State, Mention or Discuss :
   1. The common causes of industrial fire
   2. The following terms :
      (1) Flash point OR Fire point (2) Auto ignition temperature (3) Fire (4) Fuel (5) Fire resisting wall (6) Material Factor (7) Explosion data (8) Explosion hazard (9) Explosive limits (10) Initiating explosive (11) Deluge valve (12) Spray nozzle (13) Insulated equipment (14) Fire barrier (15) Inert gas system.
   3. The sources of explosion OR Types of explosion hazards.
   4. Dust explosion, its characteristics and methods to prevent it.
   5. The methods of explosion protection and relief.
   6. Deflagration and Detonation OR VCE and BLEVE.
   7. Classification of Fire and Extinguishers.
   8. Safety provisions mentioned regarding Tire Exits' OR 'Electrical Fire' in Rule 66 A of the GFR.
   9. Classification of fire safety system.
   10. General control measures for fire.
   11. Different fire prevention activities.
   12. Fire Detection and Alarm systems.
   13. Methods of fire suppression system.
   14. Any two types of portable fire extinguishers, their method of working and how to use them.
   15. Different types of 'Fixed Fire Installations'.
   16. TAC guidelines for water hydrants OR TAC guidelines for water spray system.
   17. Methods to control fire and explosion in flammable substances.
   18. Hazards and precautions while fighting fire of pesticides.
   19. Effects of combustion products and control measures for them.
   20. Which type of fire extinguisher or system you would use to control fire at following places OR State to which class of fire each one of following belongs?

(1) Electrical switch board (2) Computer room (3) Paper mill (4) Electrical cables or electric substation (5) Oleum tank (6) Benzene tank (7) Saw mill (8) Rubber mill (9) Textile industry (10) Vegetable oil storage (II) Tins of oil & grease (12) Paint or varnish containers (13) CNG bus (14) LPG car (15) Sodium metal burning (16) Aluminium cabin (17) Ammonia spheres (18) Tank of sulphuric acid (19) Pesticide go-down (20) Diamond factory

21. Actions which reduce probability officers in industry.
22. Various types of fire prevention and protection system required in a chemical plant handling flammable materials.
23. Advantages and limitations of different types of portable fire extinguishers.
24. What is a water sprinkler system and how does it help in fire fighting?

2. Write Short Notes on :

1. Nature of fire.
2. Factors OR Causes of fire.
3. Flame proof enclosure.
4. Spontaneous ignition.
5. Fire pyramid or Triangle.
6. Fire load.
7. Effects of explosion.
8. Explosion venting devices.
9. Dimensions prescribed in Rule 66A, GFR regarding Tire Exits'.
10. First aid fire fighting arrangement.
11. NFPA code.
12. Fire resistance of building materials.
13. Lightening protection of buildings.
14. Principles of fire prevention and reduction.
15. Hot work permit.
16. Fire retardant treatments.
17. Foam Extinguisher OR DCP Extinguisher.
18. Halon gas Extinguisher.
19. Electrical fires.
20. Fire emergency action plan.
21. Different classes of fire extinguishing media.
22. Types of foam used to extinguish fires.

3. Explain the Difference between :

1. Detonation and Explosion.
2. Detonation and Deflagration.
3. Flash point and Fire point.
4. Flash back and Flash fire.
5. Smoke vents and Venting fire.
6. VCE & BLEVE OR CVCE & UVCE.
7. Class A fires arid Class E fires.
8. High and low explosive.
9. Types of explosion and Effects of explosion.
10. Fire stopping and Fire check zones.
11. Fire prevention and Fire protection.
12. Fire fighting and Salvage.
13. Soda acid extinguisher and CO_2 extinguisher.
14. DCP extinguisher and Foam extinguisher.
15. Automatic Fire Detection and Extinguishing system.

4. **Comment on following explaining whether it is true or not:**
   1. Many examples of fire have been reported where many people died and many injured.
   2. Causes of fire are not many. One or two causes play role in starting fire.
   3. There is no need to classify fire. All fires are fire. They can be extinguished by water.
   4. Regular maintenance of fire fighting equipment is most important.

CHAPTER – 14

Machine Guarding

THEME

1. REQUIREMENTS OF MACHINE GUARDING

Machine guarding is required as a basic need as well as statutory requirement.

1.1 Basic Need and Importance :

Basic need of machine guarding is to protect against contact with the dangerous and moving parts of a machine, work in process and failure due to mechanical, electrical, chemical or human causes. The guards remove workers' fear and thereby increase their morale and the production. They allow the operation at higher speeds and compensate the expenditure on guarding.

Where danger exists from machinery, safe working practice alone is insufficient and cannot, be relied on from safety point of view. Guards are essential as an engineering and built-in control to prevent accident when other precautions fail.

See Table No. 5.6, 5.8, 5.20, 5.21 and 5.23 of Chapter-5 for accidents due to machinery. Absence or defect of guard is the main cause of accidents due to moving machines or their dangerous parts. Types of such dangerous parts are many. See Part 3.3 for their details.

It is obvious that when cutting edges of sharp tools, rotating and projecting parts, point of operation or contact point of die and punch, nip (contact) points of pulley -.belts or gears, rollers, calendar rolls, traversing tools or bed etc. are unguarded and workers are exposed to such openly moving i.e. unguarded parts, their risk of accident is highest. Long sleeves (shirt), sadis, chain, i.e. muffler, shawl etc can trap or entangle into unguarded rotating parts and serious or fatal accidents are possible. Many such accidents have happened also. Therefore, basic need of machine guarding must first be understood.

Mainly machine guarding is of two types: (1) Guarding for points of operation i.e. guarding for cutting edges, tool points, press or shear points, nip or running contact points, feed points etc., and (2) Guarding for Power Transmission Machinery i.e. gem's, •pulley-belts, couplings, clutches, brakes, cams, shafts, rolls, rods that transmit energy and motion from the source of power (prime mover) to the point of operation.

1.2 Statutory Requirement:

Besides its basic need, machine guarding is a statutory requirement since a century. With the growth of industrialisation, need of machine guarding was noticed and incorporated by the enactment of the Factories Act in England in 1844 and in India in 1881.

The ILO Convention (No. 119) and Recommendation (No. 118) of 1963, regarding 'Guarding of Machinery' require national laws or regulations to provide guards on dangerous machine parts before sale or purchase of machinery.

The Factories Act of 1881 was amended in 1891, 1911, 1922, 1923, 1926, 1931, 1934, 1948, 1976 and 1987 to gradually include more and more aspects of safety and other provisions. The present Act known as the 'Factories Act 1948' contains Chapter-IV on safety which includes many provisions of machine guarding. The Gujarat Factories Rules 1963 provides further details to supplement these provisions. The whole subject of the Factories Act and Rules is separately dealt with in Chapter-27, but, some relevant portion is give below:

Definitions : The Factories Act defines as under:

Power means electrical energy or any other form of energy which is mechanically transmitted and is not generated by human or animal agency.

Prime mover means any engine, motor or other appliance which generates or otherwise provides power.

Transmission machinery means any shaft, wheel, drum, pulley, system of pulleys, coupling, clutch, driving belt or other appliance or device by which the motion of a prime mover is transmitted to or received by any machinery or appliance.

Machinery includes prime movers, transmission machinery and all other appliances whereby power is generated, transformed, transmitted or applied. Belt includes any driving strap or rope.

Maintained means maintained in an efficient state, in efficient working order and in good repair.

Fencing of Machinery : Section-21 requires that every moving part of a prime mover, flywheel, headrace and tailrace of water wheel and turbine, lathe, electric generator, motor, rotary converter, transmission machinery and every dangerous part of any other machinery shall be securely constructed, positioned or fenced by safeguards of substantial construction and constantly maintained and kept in position while the parts of machinery they are fencing are in motion or in use.

Work on or near machinery in motion: Section22 requires that any examination, lubrication, adjusting operation, mounting or shifting of belts while the machinery is in motion shall be carried "out by a specially trained adult male worker wearing tight fitting clothing supplied by the occupier and his name shall be recorded in the register in Form No. 8. Such worker shall not handle a belt at a moving pulley unless the belt is not more than 15 cm in width, the pulley is a normal drive (no flywheel or balance wheel), the belt joint is laced or flush with belt, the pulley, joint and pulley rim are in good repair, there is reasonable clearance to work, secure foothold / handhold are provided and any ladder being used is secured fixed or held by a second person. At that time other parts in motion shall be securely fenced to prevent their contact. Woman or young person is not allowed to do such work.

Employment of young persons on dangerous machines : On power presses except hydraulic presses, milling machines, guillotine machines, circular saws and platen printing machines no young person shall work unless he has been fully instructed regarding their dangers and precautions to be observed and has received sufficient training to work on that machine and is under adequate supervision by a person who has a thorough knowledge and experience of that machine (Sec. 23 & Rule 57).

Striking gear and devices for cutting off power: Suitable striking gear or other efficient device to move driving belts to and from fast and loose pulleys and to prevent the belt from creeping back on to the fast pulley, shall be used and maintained. Driving belts not in use should not rest or ride upon shafting in motion (for which belt hangers are necessary). Other devices for cutting off power are necessary in every work room. Such devices shall be so locked to prevent accidental starting of the machinery.

Self acting machines : 45 cm or more clear space is necessary from the end of maximum traverse of any self-acting machine or material carried thereon.

Casing of new machinery : Every set screw, bolt, key, gearing shall be completely encased or guarded to prevent danger.

Work near Cotton-openers : No woman or child shall work in a room where cotton opener is at work. If the feed-end is fully partitioned from the delivery end, their employment on feed-end side is permissible.

Revolving machinery : Effective measures are necessary to ensure not to exceed the safe working peripheral speed of every grinding wheel, revolving vessel, cage, basket, flywheel, pulley, disc or similar appliance driven by power. A notice indicating maximum safe working peripheral speed of the grinding wheel, speed of the shaft or spindle upon which the wheel is mounted and the diameter of the pulley to secure safe working peripheral speed of grinding wheel shall be affixed near each such machine. Effective brake is also required.

Further Safety Precautions: Rule 54 prescribes machine guarding details in respect of textile machinery, cotton ginning machinery, wood-working machinery, rubber mills, centrifugal machines, power press and shears, slitters and guillotine machines.

Part 4.4 of this Chapter describes guarding of some such machines.

2 INDIAN STANDARDS

Many Indian Standards are available. A few are given below in Table 14.1:

No.	Subject	IS No.
1	List of IS on Safety, Mechanical Engineering, Foundry Industry, Automobile Industry and Agricultural Equipment Industry.	--
2	Drilling, Safety code	4081
3	Compressors safety	11461
4	Conveyor safety	6687, 7155
5	Printing machinery safety	12619
6	Unfired pressure vessel	2825
7	Belting for power transmission (part I for Flat belt, Part II for	2122

	Vee-belt)	
8	Care and practice of abrasive wheels	1991
9	Degrees of protection provided by enclosure for rotating electrical machinery	4691
10	Wood working machines (Part 1 to 24)	8964
11	Mechanical Guarding of Machinery	9474
12	Mechanical Press	7468, 7469, 10644
13	Machine – shaft heights	2031
14	Machine – metal forming terminology	6652
15	Machine – working level height	7229
16	Machine tools – safety requirements	11016

These standards are useful from design to maintenance purposes..

3 PRINCIPLES OF MACHINE GUARDING

3.1 Definitions :

1. **Point of operation:** That area on a machine where material is positioned for processing by 'the machine and where work is actually being performed on the material.

2. **Zero Mechanical State (ZMS):** The mechanical state of a machine in which every power source that can produce a machine .member movement has been shut/locked off. This means deenergised, de-pressurised and neutralized condition of the machine or equipment which provides maximum protection against unexpected mechanical movement.

3. **Power off:** The state in which power (electric, pneumatic, hydraulic, atomic etc.) cannot flow to the machine is considered a power-off stage.

4. **Power-locked off:** The state in which the device that turns power off is locked in the off position with the padlock of every individual who is working on the machine.

5. **Guarding:** Any means of effectively preventing personnel from coming in contact with the moving parts of machinery or equipment which could cause physical harm to the personnel. In case of a power-press, a cover on point of operation (die and punch) is called 'guard' while those on other danger zones are called 'enclosure' or 'safeguard'.

   Safety by Guarding is most important as other methods are not always possible. Depending upon the dangerous part, its size, position, speed etc., a guard should be selected. Generally the parts to be guarded fall within three categories:

   1. The prime mover.
   2. Transmission parts from the prime mover to the machine and the transmission parts in the machine itself. It is desirable to minimise them and enclose completely.
   3. Operating parts of a machine, of which the points of dangerous operation need effective guarding.

6. **A machine guard** means any enclosure, barrier or device constructed to prevent a person or his clothing coming into contact .with dangerous parts of the machine. The point of operation is that

part of working machine at which cutting, shaping, forming or any other necessary operation is accomplished. A guard for that part is known as the point of operation guard.

7. **Enclosures:** Guarding by fixed physical barriers that are mounted on or around a machine to prevent access to the moving parts.

8. **Fencing:** Guarding by means of a locked fence or rail enclosure which restricts access to the machine except by authorised personnel, Enclosures must be a minimum 1m (42 in) away from the dangerous part of the machine.

9. **Safety by Position or Location:** It is a guarding as a result of the physical inaccessibility of a particular hazard under normal operating conditions or use. Words "Safe by location" or "Safe by position" are used to denote safety by distance.

   The words "safe by position" are used by Section-21 of the Factories Act. It means the situation (out of reach) or position in such a way that normally it is not possible to touch the dangerous parts. However intentional contact should be prevented. Moving feed opening can be made safe by position if gravity or remote feeding device is applied. But, then, it is a type of indirect guarding. A distance of 2.6 m or 8'6" is considered safe by position.

10. **Ingoing (in-running) Nips:** A hazard area created by two or more mechanical components rotating in opposite directions in the' same plane and in close conjunction or interaction e.g. calendar rolls, in running rolls of textile or paper machines.

11. **Safety by Construction :** It indicates parts so constructed as to cause no hazard, viz. shaft, sliding and link mechanism so located or with slow speed that their contact is not dangerous. Built-in-safety- is the similar word for designing and constructing new machinery in such a way to make the dangerous parts safe by deep housing or position etc.

3.2 Elimination of Hazard :

Hazards from machinery are generally of following types:

Crushing, shearing, cutting or severing, entanglement, drawing-in or trapping, impact, stabbing or puncture, friction or abrasion, ejection of material from the machine, contact with moving part, hot surface or sharp edge, free fall of any material, tool or equipment and high pressur-e-fluid ejection.

The basic steps to prevent accidents are :

1. Eliminate the hazard from the machine, method, material, structure etc.
2. Control the hazard by enclosing or guarding it at its source.
3. Train personnel to know that hazard and to follow the safe job method to avoid it and
4. Use personnel protective equipment necessary.

Thus machine guarding is one of the basic step to eliminate hazard. Actually the machine should be so designed and constructed that all safety points are incorporated by built-in safety principle and need of extra guards should be minimum. A machine safety checklist given by the NSC, USA is worth mentioning. It suggests:.

1. Design the machine so that it is impossible for an operator to get at the point of operation or any other hazard point while the machine is working.
2. Design the machine so that corners and edges
3. Locate machine controls so that the operator will not be in "the vicinity of the point of operation while actuating the controls.
4. Place the control so that the operator will not have to reach too far or move his body off balance in order to operate the machine.
5. Build power transmission and drive mechanisms as integral parts of the machine.
6. Build overload devices into the machine.
7. Design the machine for single-point lubrication.
8. Design mechanical, instead of manual holding devices.
9. Design a mechanical device for feeding and ejecting parts so as to eliminate the use of hands for such operations.
10. Minimise motor drift-time.
11. Provide fail-safe interlocks so that the machine cannot be started when it is being loaded or unloaded or being worked on.
12. Provide a grounding system for all electrical equipment.
13. Provide standard access platform and ladders for inspection and maintenance of equipment.
14. Design component parts of equipment for easy and safe removal and replacement to facilitate maintenance.
15. Reduce sources of excessive noise, vibration, heat etc.

Such built-in-care in construction principles of a machine or equipment should also ensure that it will cause no harm to the environment, no discomfort to the operator, no operational contingencies, no contact with overheated or chilled surfaces,, no electrical accident and no access to the danger zone.

See also Part 4.2 for built-in safety devices.

3.3 Groups of Dangerous Parts :

Some examples of dangerous parts of machines are shown in fig. 14.1. They pose hazards and there fore they need appropriate machine guards or fancing.

3.3.1 According to Motions :

Dangerous parts to be guarded according to their motions are generally classified as follows :

Group-1. Rotary Motions : (1) Rotating parts alone viz. shafts, coupling, spindles, projections on moving parts, fly-wheel, saw, gear, knife, cutting tool etc. (2) In-running nips subdivided as (a) Between parts rotating in opposite direction - gears, rolls etc. (b) Between rotating and tangential moving parts conveyors, belt drives, rack and pinion etc. (c) Between rotating and fixed parts - grinding wheel, paper machine felt or roll, drums, cylinders, worms, spirals etc.

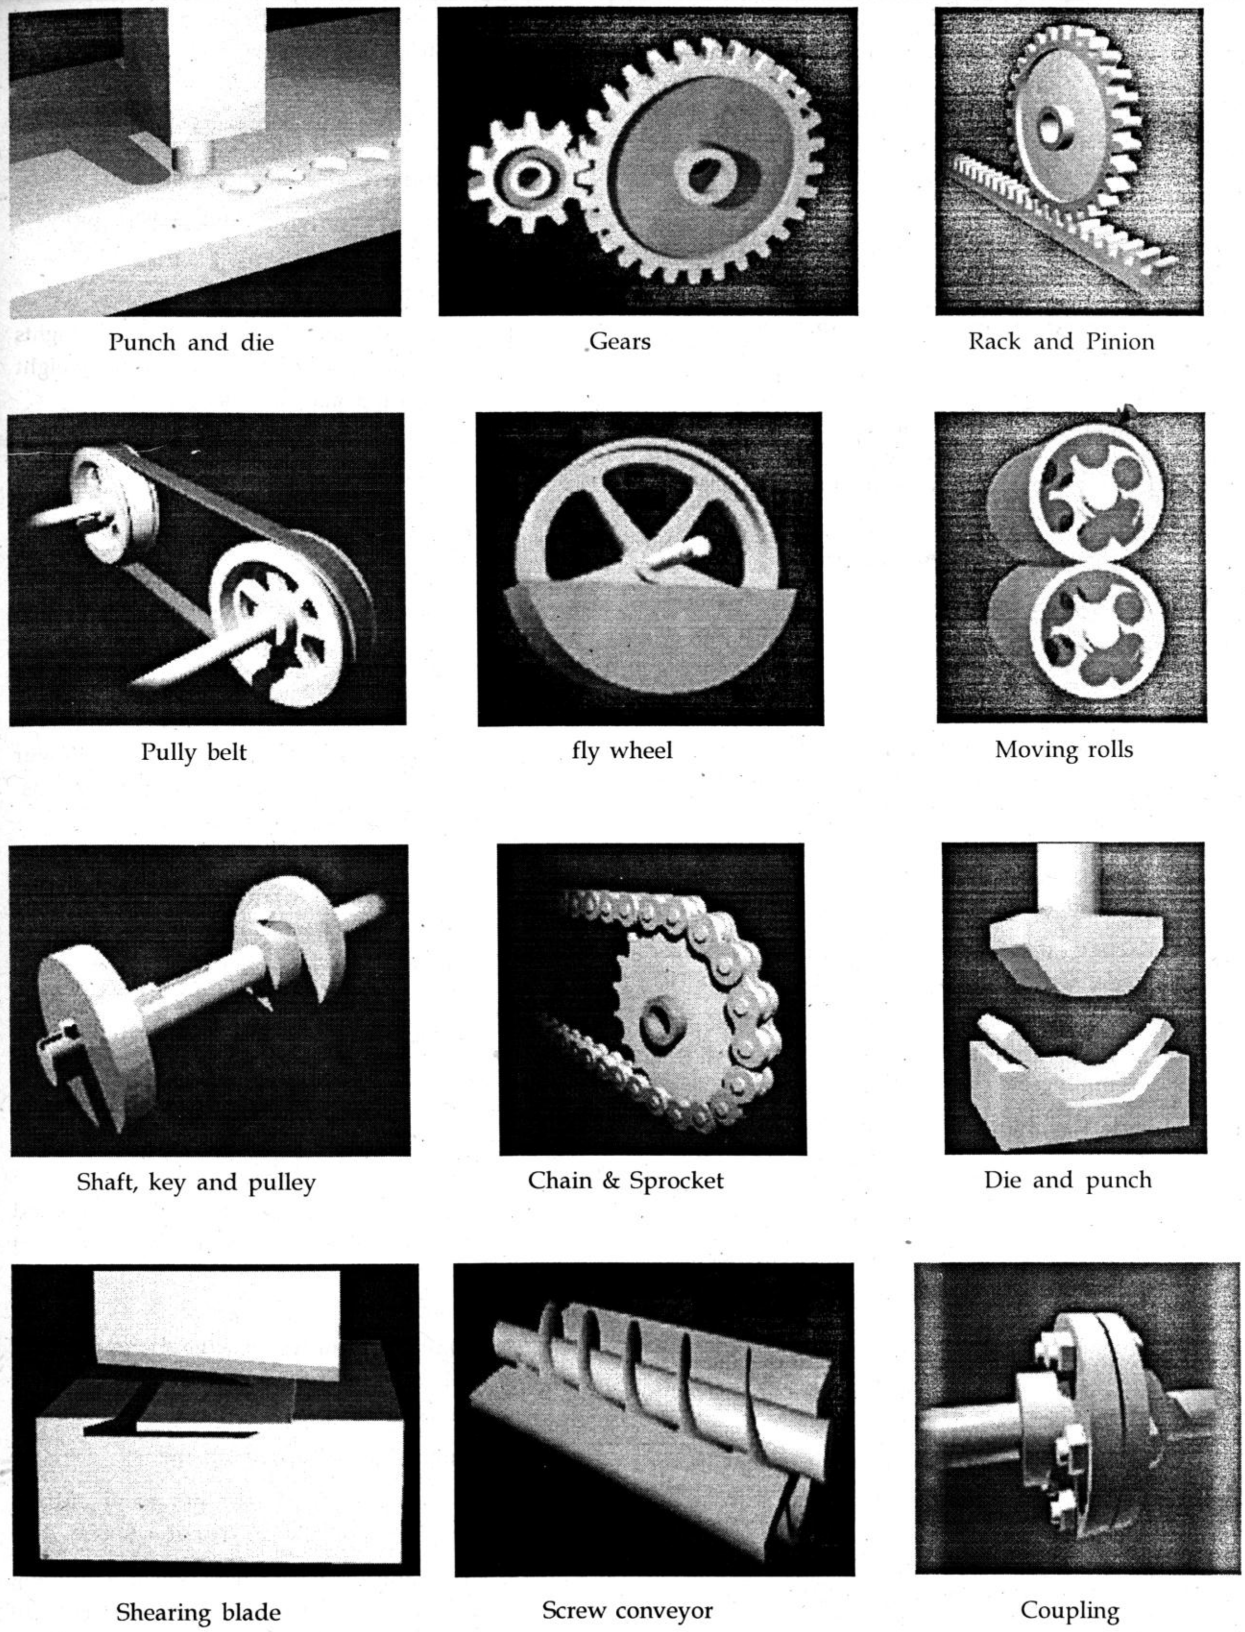

Fig. 14.1 Examples of dangerous parts of machines

Group-2. Reciprocating Sliding Motions : (1) Reciprocating sliding motions and fixed parts (a) Approach type - danger of crushing viz. slides (rams) on power presses and forging hammers, pistons, cross rod of a steam engine and riveting machines (b) Passing types - danger of shearing, viz. planning machine, shaper, spot welder clamping fixtures, guillotine and the shear, power press etc. (2) Single sliding motion- abrasive or sharp nature of objects such as saws or crocodile clips on belts.

Group-3. Rotating/ Sliding Motion : A cam gear having sliding and turning movement etc. falls within this group.

Group-4. Oscillating Motions : Trapping points between two moving parts or between a moving part and a fixed object viz. a pendulum, crankshaft, closing platens etc.

3.3.2 According lo H.A. Hepburn

25 groups of intrinsically dangerous parts of machinery as classified by H.A. Hepburn are as follows:

(a) Single Revolving Units - Risk of entanglement

1. Revolving open arm pulleys and other discontinuous rotating parts - Fan blades, spur gear wheels etc.
2. Revolving worms or spirals in casing Meat mincers, rubber extruders, spiral conveyors.
3. Projections on revolving parts - Key heads, set screws, cotter pins, complying belts etc.
4. Revolving shafts, spindles, mandrels and bars - drills, reamers, boring bar, stock bar, milling etc.

(b) Single Revolving Units - Risk of cutting or abrading

5. Revolving high speed cages in casings Hydro-extractors, centrifuge.
6. Revolving or oscillating mixer .arms in casings - Dough mixture, rubber solution mixture.
7. Revolving drums and cylinders - uncased - Rumbles, shaking barrels, rag digesters etc.
8. Revolving cutting tools - Circular saws, milling cutters, shears, routers, chain mortisers.
9. Abrasive wheels - Grinding wheels etc.

(c) In-running Parts - Risk of nipping and tearing

10. In running nips of the belt and pulley type - Pulley - belt, chain and sprocket gear, conveyor belt etc.
11. Revolving beaters, spiked cylinders and drums - Scutchers, cotton opener, laundry washers.
12. In running nips between pairs of revolving parts - Gear wheels, friction wheels, calendar bowls, mangle rolls etc.
13. Nips between, gears and rack strips. (d) Reciprocating Tools or Parts - Risk of cutting or crushing
14. Moving balance weights and dead weights - Hydraulic accumulators, balance weight on slotting machine etc.
15. Reciprocating knives and saws Guillotines for metal, rubber and paper cutting, trimmers, perforators etc.
16. Nips between reciprocating and fixed parts other than tools and dies - Sliding table and fixture, shaping machine and fixture.
17. Closing nips between platen motions Letter press platen printing machine, power presses.
18. Reciprocating tools and dies - Power presses, drop stamps, relief stamps, bending press, revolution press.
19. Nips between revolving control handles and fixed part - Traverse gear handles of lathes, milling machine etc.

20. Nips between revolving wheels or cylinders in pans or on tables - Sand mixtures, edge runners, crushing mill, mortar mill etc.
21. Nips between fixed parts and unidirectional moving parts - Buckets or hoppers or conveyors against tipping-bars etc.
22. Nips between connecting rods or links and rotating wheels, cranks or disc - Flat bed printing machine, jacquard loom, automatic looms.
23. Pawl and notched wheel devices for intermittent feed motions - Planer tool feed motion, power press dial feed table etc.

(e) Running Edges - Risk of cutting

24. Cutting edges of endless band cutting machines - Band saws, band knives.
25. Projecting belt fasteners and fast running belts - Bolt and nut fasteners, wirp pin fasteners, centrifuge belt etc.

Above discussed motions are shown in figure 147 143 and 144

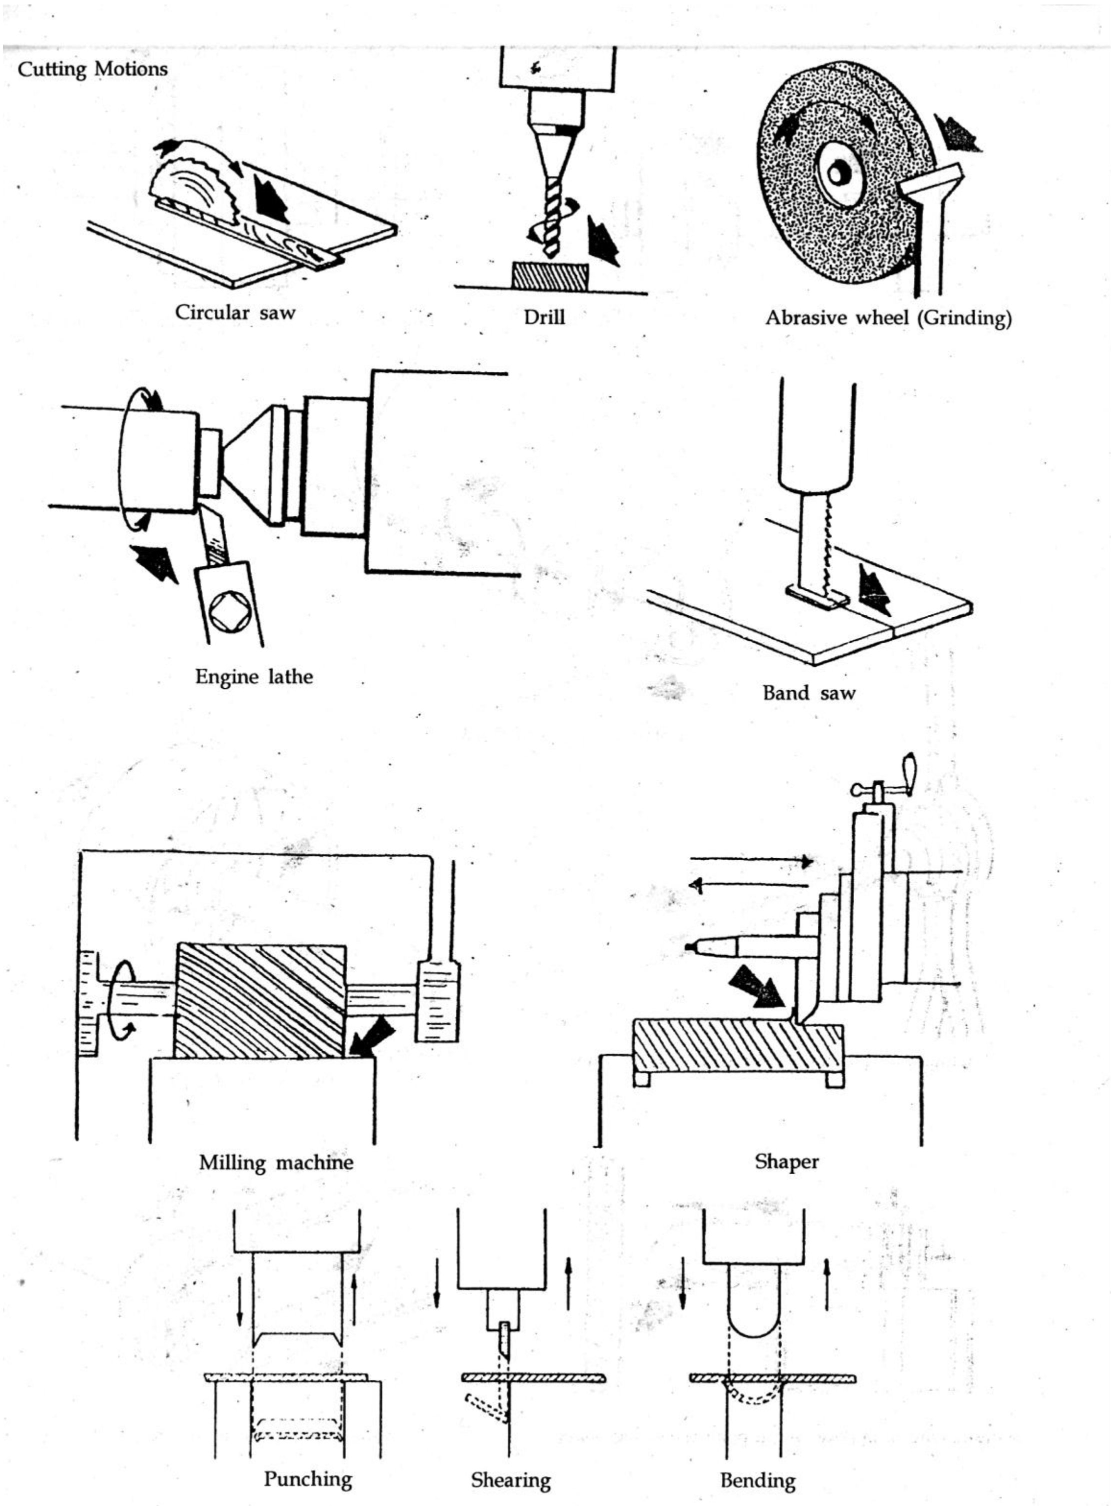

Fig. 14.2 Different types of machine motions (indicating hazards also).

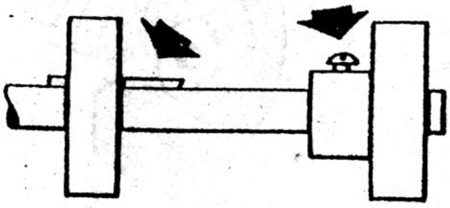
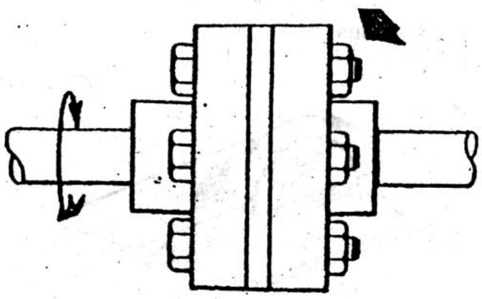
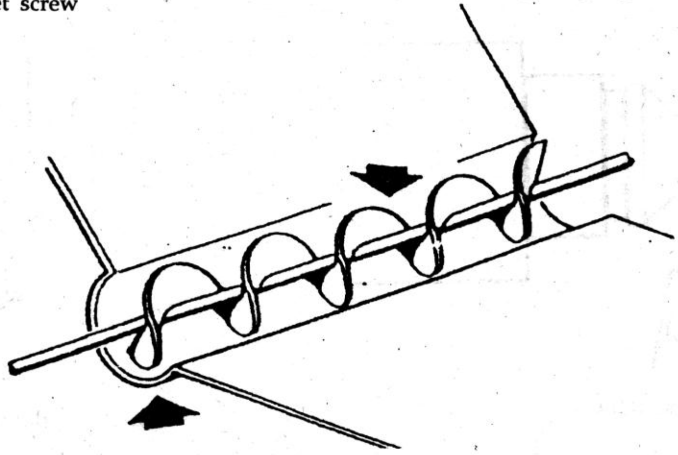


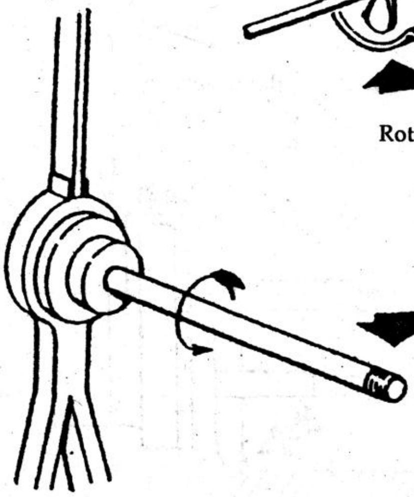
Rotating shaft and pulleys with projecting key and set screw



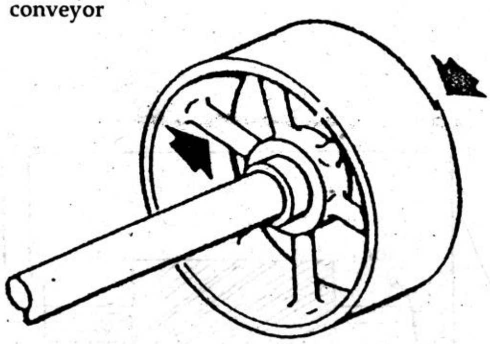
Rotating coupling with projecting bolt heads



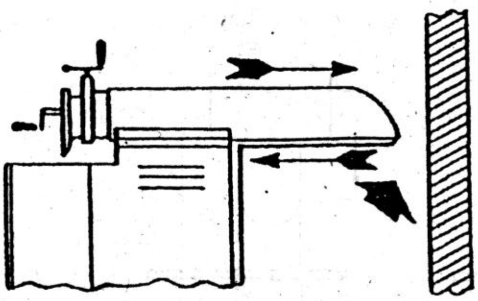
Rotating motion of screw conveyor



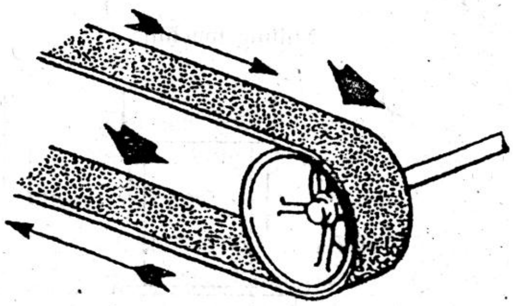
Rotating bar stock at the end of screw machine



Rotating pulley with spokes and projecting burr on face (edge) of pulley



Reciprocating head creats pinch point with fixed object.



Transverse motion of pulley and belt.

Fig. 14.3 Examples of rotating, reciprocating and transversing motions (indicating hazards also).

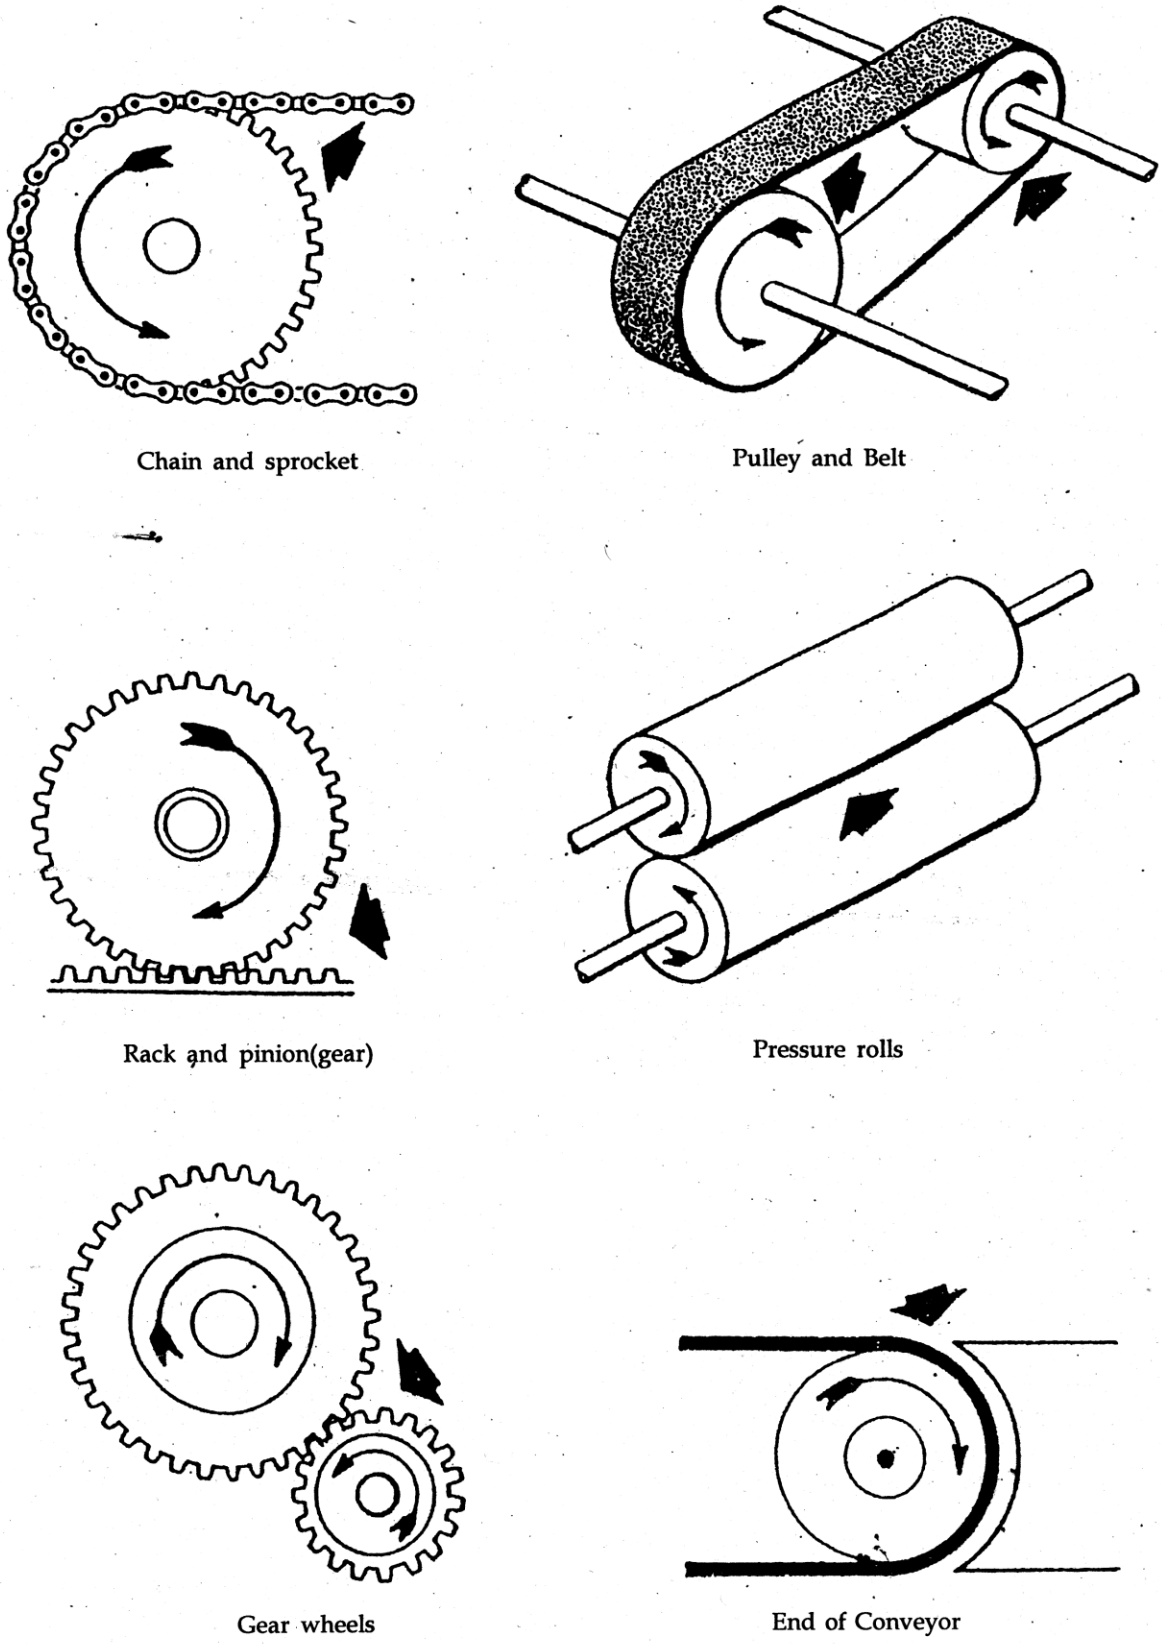


Fig. 14.4 Examples of inrunning nip points(hazards) where nip guards are required.

3.4 Requisite Characteristics (Design principles) of Guards:

Twelve characteristics, design principles, specifications, basic requirements or good guarding practice for machine guarding are:

1. With its primary purpose of protection, it should also facilitate the work i.e. it should be convenient, reliable and not hampering the work or rate of production.
2. It should fully satisfy the legal provisions and IS prescribed i.e. it should conform the standards, be a complete guard and not incomplete or giving any access to the part to be protected. It should be as close as possible.
3. It should be suitable and effective to the job and the machine. It should not weaken the machine.
4. It should allow for oiling, inspection, adjustment and repair. If it requires opening for this purpose, it should be easily and quickly replaceable.
5. It should withstand wear, shock, vibration and long use with minimum maintenance. If it requires frequent opening and closing, this factor becomes more important.
6. It should be of proper material and construction. It should be well fitted. Fire and corrosion resistant material is preferable..
7. It should be free from self-hazard such as sharp or rough edges, nails, splinters, more opening, noise, vibration etc.
8. If visual watch of operation is necessary, it should be transparent and yet durable.
9. If dusting is possible as in case of machining of wood, rubber, brass, cast iron etc., apart from the guard, dust suction device should also be fitted as a special guarding.
10. It should be fail-safe i.e. if it fails or breaks it should stop the machine or at least it should give warning (alarm) to stop the machine.
11. It should be interlocking type i.e. the machine will not start till it is not closed and will stop soon if it is opened.
12. It should fulfil special requirement depending upon its purpose viz. distance guard should provide sufficient protective distance, trip guard must immediately trip the machine etc.

It may be difficult to fulfil all these requirements but it is desirable that safety engineers must design guards by keeping above points in mind. If it is no possible to provide guard without interfering with production, safety should be preceded over production Similarly when complete protection is not possible incomplete (maximum possible) protection, should b(preferred to no protection.

4 TYPES AND GUARDS SELECTION OF

Ways and means for machine safety can be classified as under :

Machine Safety

- Safety by construction
- Safety by position
- Built-in safety
- Safety by machine controls
- Safety by precautions and maintenance
- Safety by Guarding prime mover, transmission parts and points of operation
  - Fixed guards or fencing
    1 Total enclosure
    2 With .limited access
    3 With adjustable access
    4 Distance or barrier guard
  - Interlock guards.
    1 Mechanical interlocking
    2 Electrical interlocking
    3 Tripguard
    4 Control guard
  - Automatic guards
    1 Mechanical type-sweep, knock or push away guard
    2 Photo-electric cell type
  - Safety devices
    1 Two-hand control
    2 Optical sensor
    3 Electro-magnetic sensor
    4 Mechanical feed (conveyor)
    5 Feed tools (tong, magnetic device)
    6 Non repeat device
    7 Pedal guard

Thus machine guarding is one of the ways for machine safety and first two modes of safety b) construction and safety by position are equally important. They are explained below in brief :

Safety by Construction : A shaft end or any par without nip, spoke, nail or protruding projection moving at very slow speed, any sliding or link mechanism moving at very slow speed without danger of trapping or crushing, a power operated sliding door which will stop or return at touch are some of the examples of safety by construction. Such unguarded slow moving parts without risk are considered safe by construction. Because of high production rate and dangerous cutting shaping operations required, this type of slow moving machinery is hardly possible. Even then safe construction of machines must always be aimed at. At least outer or exposed part must be safe.

Built-in-safety should not be understood as safety by construction. The dangerous moving parts enclosed in casing so that no separate guard is required are an example of built-in-safety. Here speed, nip or sharp edge of moving parts are dangerous if the casing is removed, therefore their construction is unsafe and safety is built-in by providing a solid enclosure so that the moving parts are neither visible nor exposed. See Part 4.2 for details.

Safety by Position: When dangerous parts are so situated by height, depth or position that it is normally difficult to touch them, they are called 'safe by position'. Overhead transmission machinery, dangerous parts out of reach because of height or covered by some structure so as to prevent access or contact, are generally called safe by possible.

However this concept does not provide full safety. Unpredictable behaviour of a 'person or. touching because of cleaning by broom stick can still cause an accident. Therefore decision regarding 'safe by position' should be thought twice with all considerations.

Feed openings where access is possible and guard is not possible, should be made safe by providing gravity, conveyor or remote control feeding. This is also a way of safety by position. Hopper depth should be sufficient so that extended arm cannot touch the dangerous part.

4.1 Types of Guards and Selection:

Unguarded dangerous machine parts are shown in Fig. 14.5. They need guards. Various types of guards are shown in fig. 14.6(A) and (B)

Various types of guards are shown classified in previous part. Their suitability should be selected. Preference should be given to the simplest type of guard ensuring complete safety. Some are described below and some in subsequent paras.

Fixed guards : They are simple, easy to provide and cover parts as well as throwing particles if any. They are of various types, materials and design. A minimum thickness of 1.2 mm is recommended for sheet metal. Guard opening and its distance from the dangerous part should be fully safe. Such spacing and distance are prescribed and formulae are also available, but it is rather a matter of fact of individual requirement. They should be close fit, robust and should withstand speed, vibration, impact etc. They should be properly fitted by clamps, bolts etc. They require special tool for their removal.

Every fixed guard (or other guard) on point of operation should prevent entry of fingers (preferably the smallest finger) or hands by reaching over, under, or around the guard into the point of operation. Its fasteners should not be easily openable to prevent misuse or accident. On point of operation it should offer full visibility, while on transmission parts it may not.

Following formula was suggested by the Chief Inspector of Factories, UK in his Report of 1975 –

$$Y = \frac{X}{12} + 6$$

where Y = guard opening or gap in mm and
X = distance from danger in mm

Fixed total enclosures are used to cover prime mover and transmission parts such as headstock gearing, belts, pulleys etc.

Fixed limited access guards provide minimum opening in the guard to insert and remove the job (material). It disallows finger to trap. If the material is jammed, it requires special tool and opening and refitting of the guard. They are used on power presses..

Fixed adjustable access guards -provide opening through or around guard to accommodate materials of different sizes. Guards on band saws, jigsaws, milling cutter etc. can be raised or lowered as per the thickness to cut. Such guard known as "crown guard" on circular saw or drill tool adjusts automatically as the job or tool moves. Its disadvantage is that it gives little protection when thin material is processed. See Fig. 14.6(B)

Fencing, distance or barrier guards make it physically difficult for people to gain access. Nip guard to in-running rolls and fixed railing or fencing to engines, motors, planning or shaping machine are of this type.

Interlock guards make certain that the machine cannot be started until the guard screen is in close position and conversely the guard cannot be removed until the working parts have been stopped. Mechanical, electrical, hydraulic or pneumatic systems are used to actuate the guard. Mechanical interlocking of a power press, card machine and electrical (limit or micro switches) interlocking of headstock covers of many textile machinery are such examples. Many times the interlocking is by-passed or made ineffective which is not good. This is its disadvantage. Correct working condition of limit switch is most important. Limit or micro switches are used but they are not fully safe.

Trip guards are actuated by anyone approaching beyond the safe position and operate a stop or reverse control viz. trip rod along the conveyor belt, hand trip on a rubber mill, electronic eye, lift door, platen printing guard, calendars or dough brakes etc.

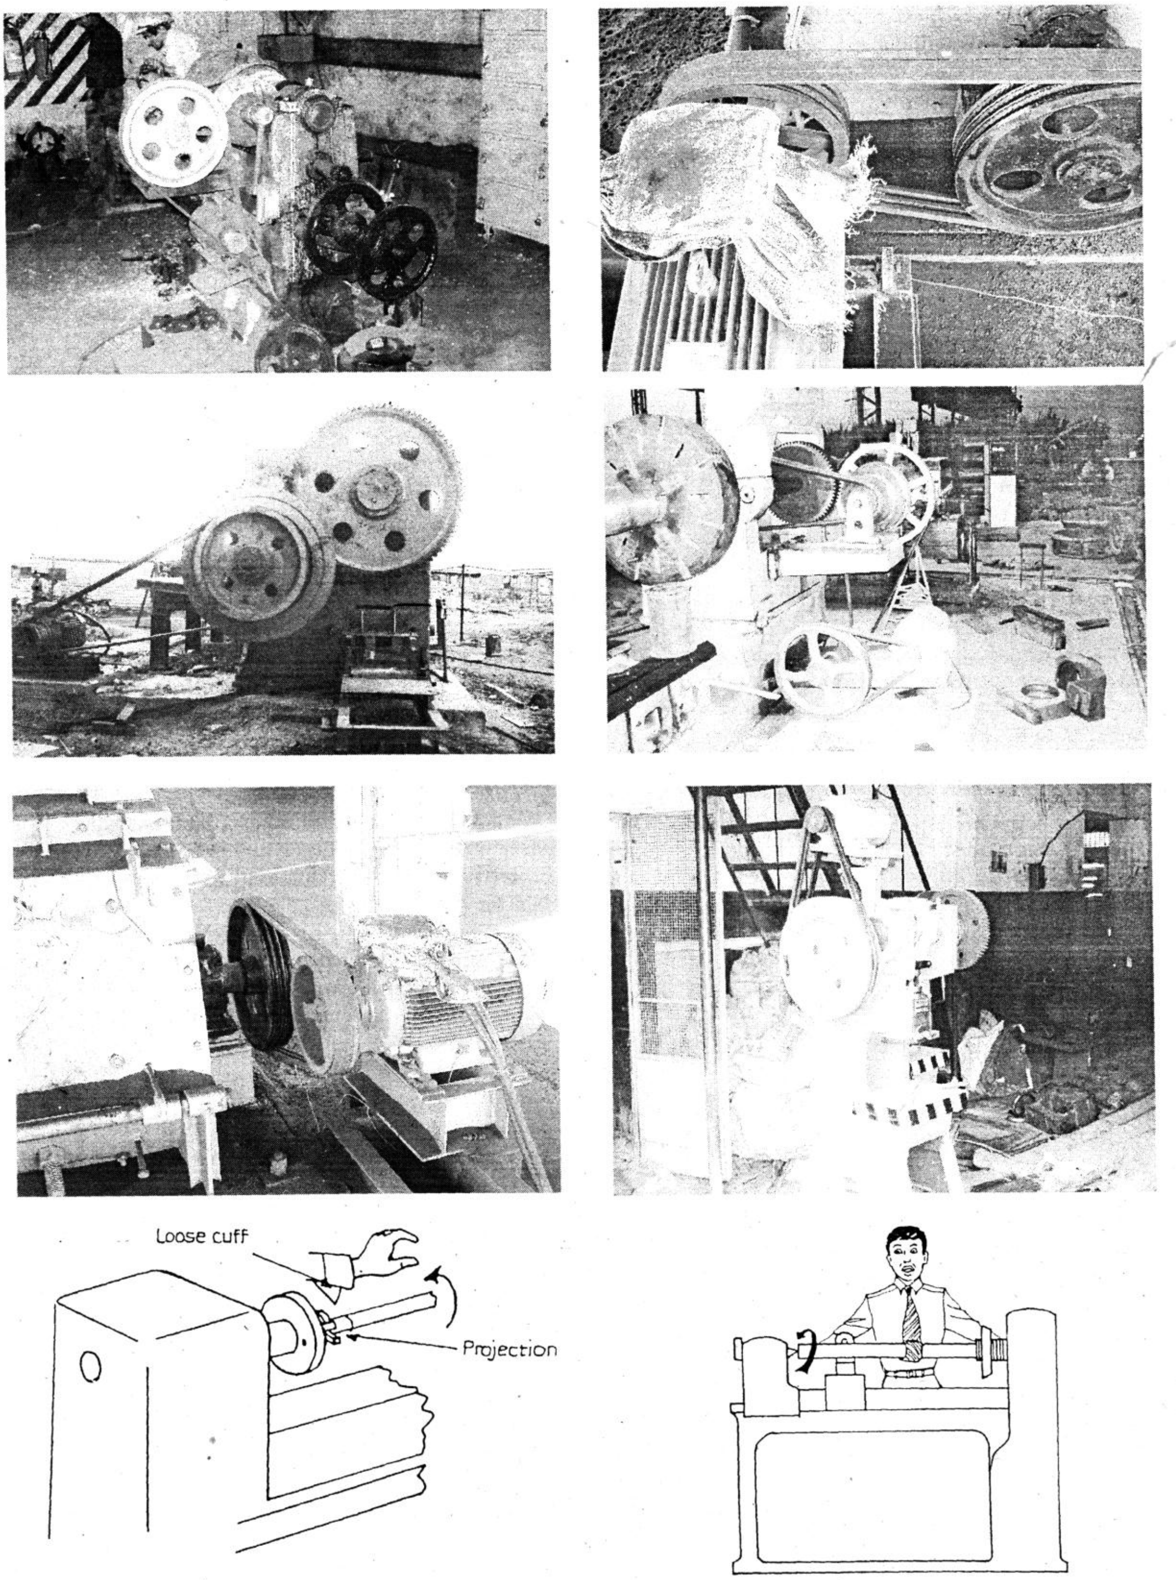

Fig. 14.5 Examples of unguarded dagerous machine parts (hazards). They need guards.

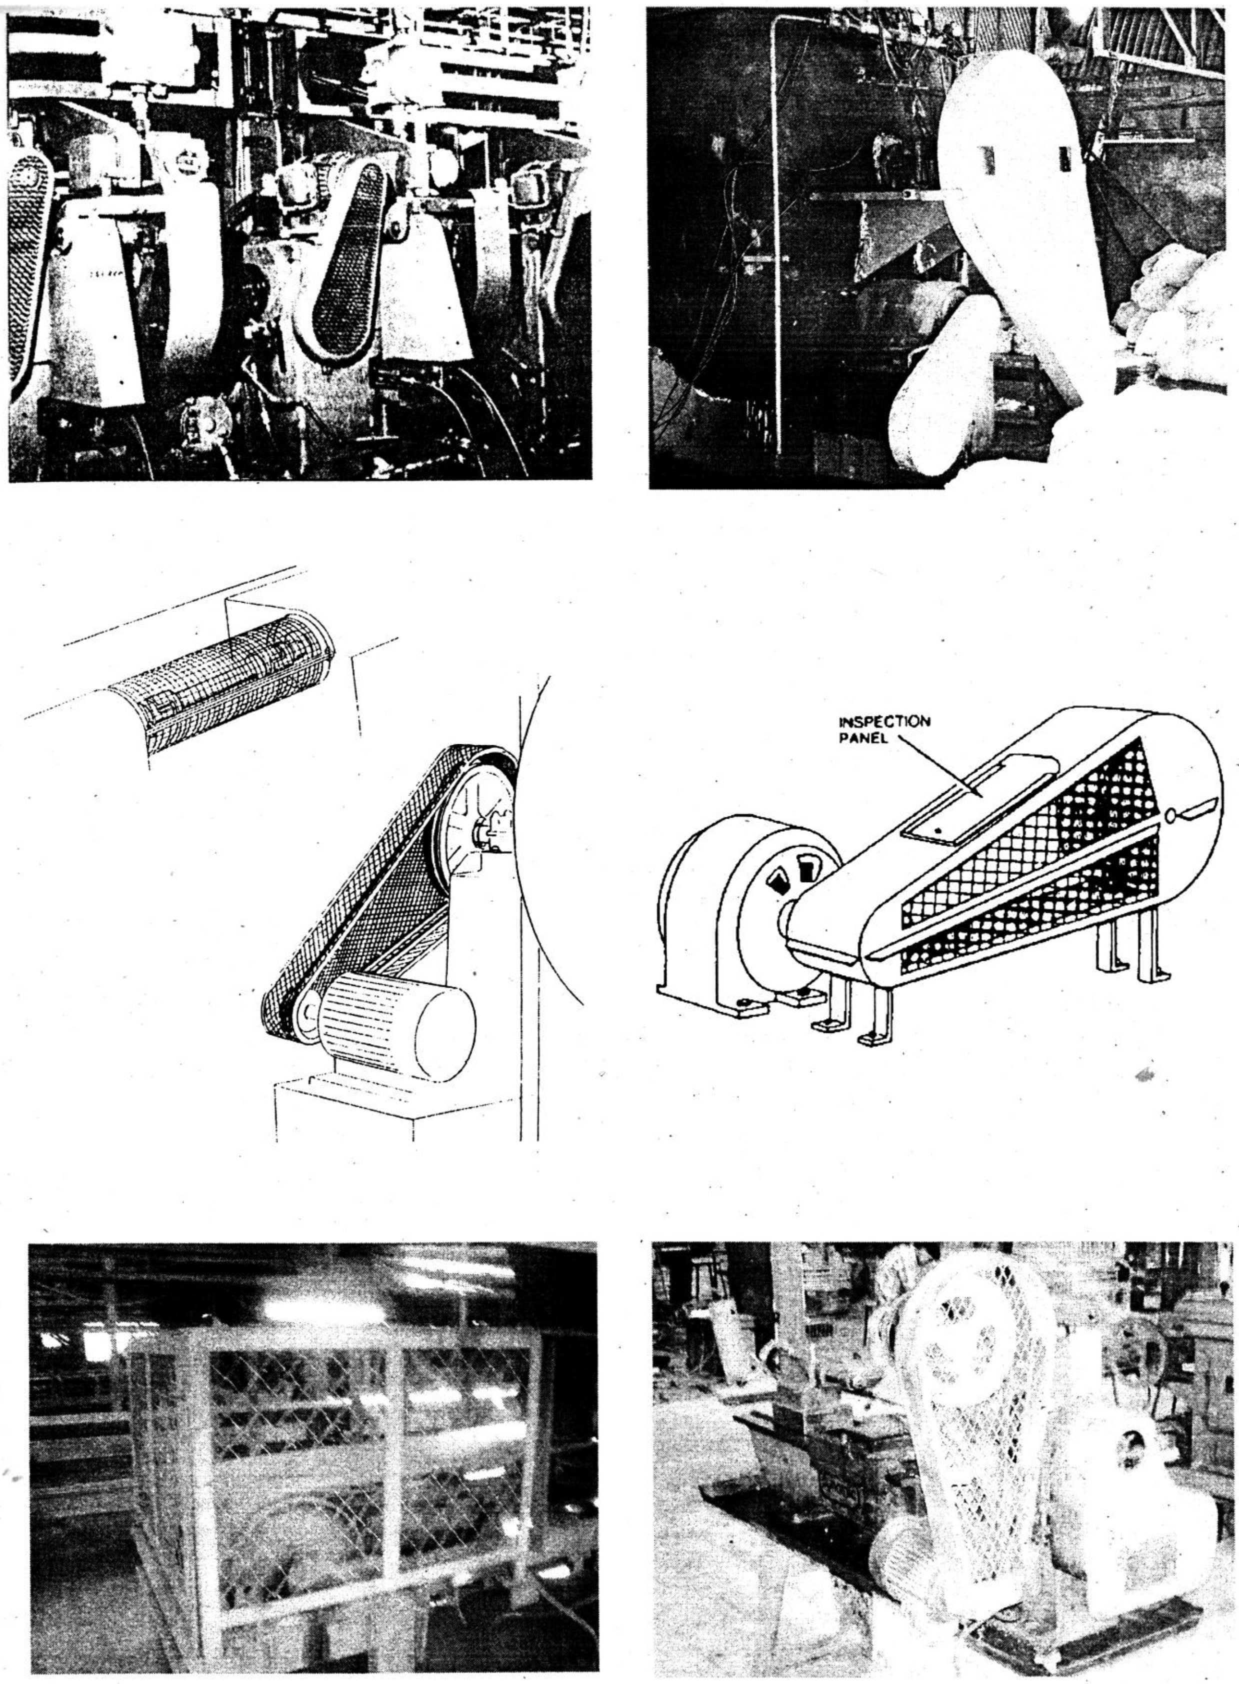

Fig. 14.6 (A) Fixed guards (elemination of hazards).

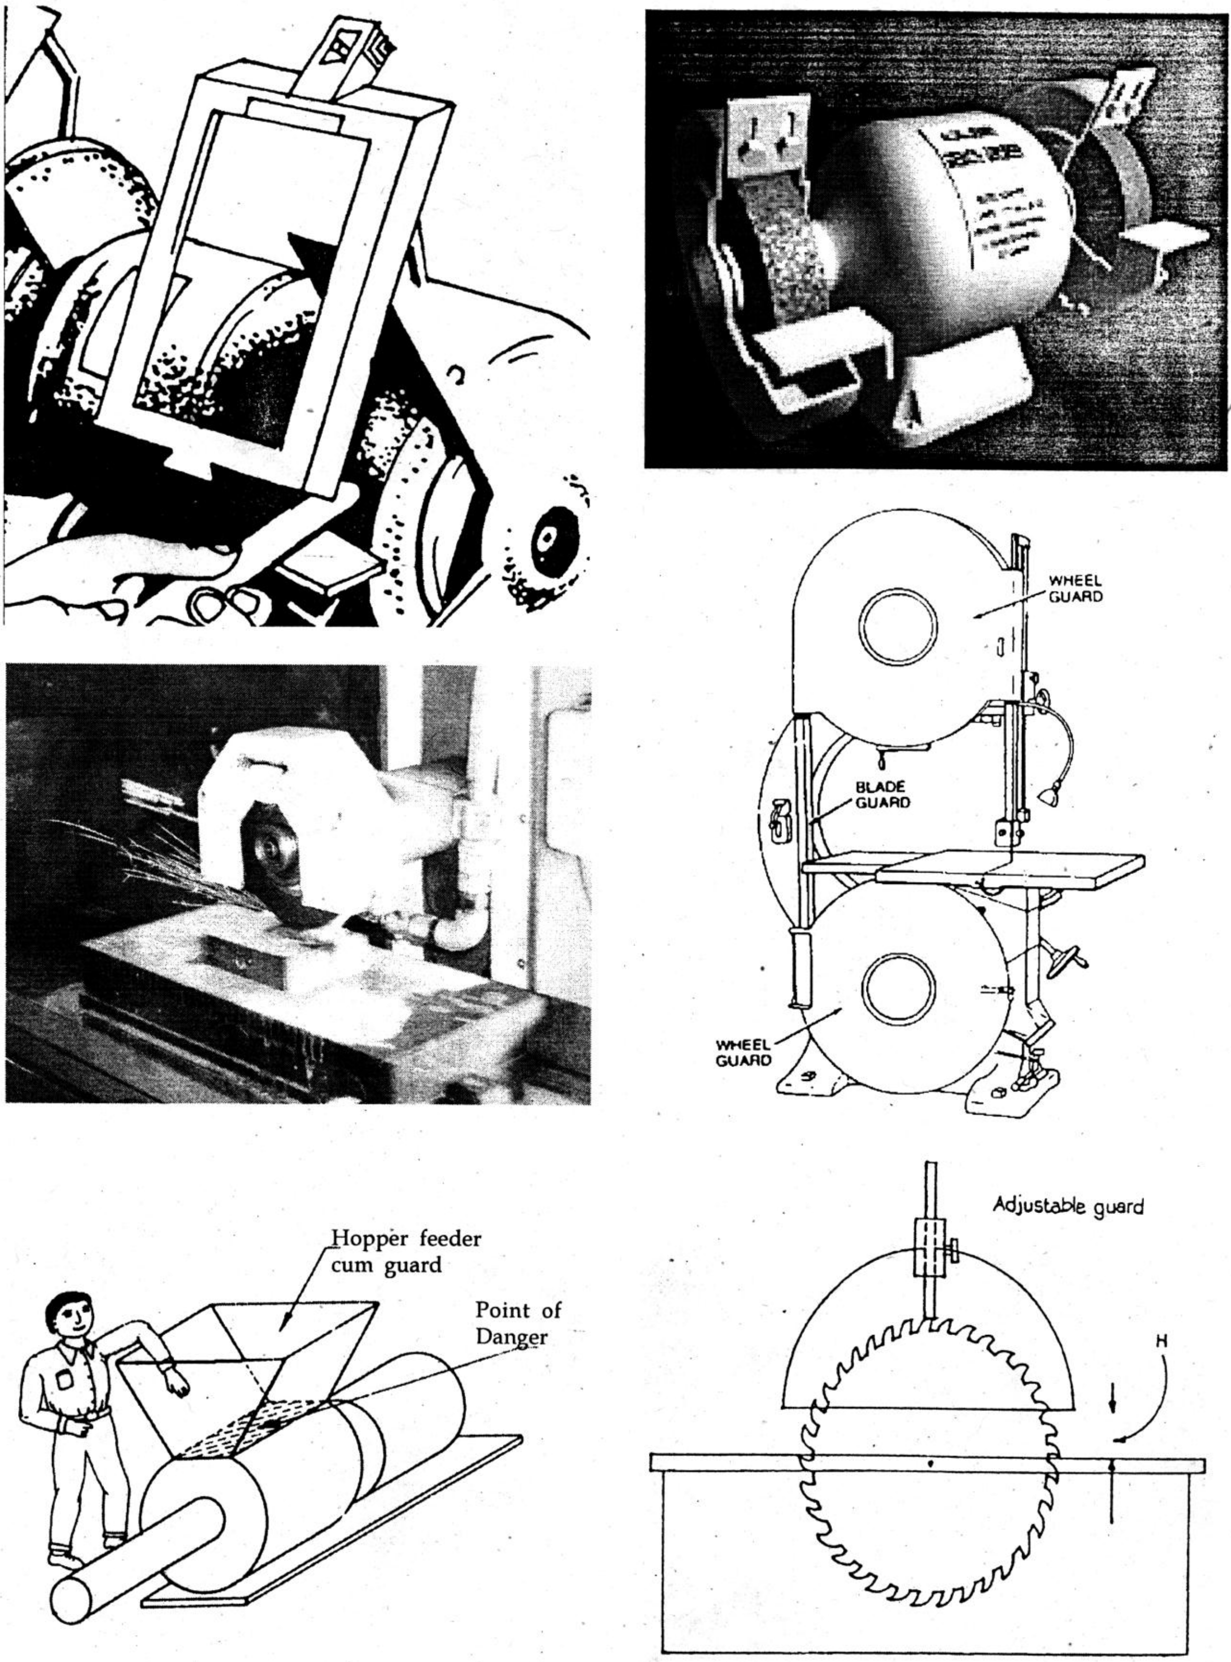

Fig. 14.6 (B) Guards of grinding wheel, circular saw, band saw and rubber mill.

Control guards activate the machine when the guard is closed and opening the guard stops it. Thus the guard acts as on-off switch. Such guard is useful for the machine which can be brought to rest very rapidly, e.g. power press.

Automatic guards will ensure that the operator is prevented from coming into contact with dangerous parts when the machine is set in motion accidentally. This guard is itself actuated by the movement of the dangerous part. It can only be used where sufficient time is available to remove the body part from the danger zone viz. sweep, knock or push away guard on a power press or platen printing machine. Because of its stroke hazard it is hardly used. Photo-electric guard (device) operates to stop the dangerous part when the light curtain is interrupted. This type of guard is used on shearing or cutting machine.

Safety by Machine Controls: These should be differentiated from incidental safety devices which are external and work like guard for protection. But the machine itself has many controls as its inherent or attached elements. All levels, buttons, brakes, pedals, switches, handles, wheels, auto controls etc., are machine controls to run the machine safely and efficiently. Such controls should be clearly identified, marked and suitably placed tot ease of operation. Their purpose and direction of movement shall be marked. Each stop button should accompany start button and they should be sunk to prevent accidental pressing.

Levers should be capable of being locked in position. Levers, handles, or wheels should operate to give naturally anticipated direction (e.g. clockwise close and anticlockwise open, up forward, down reverse etc.), controls should be at rest when power is applied and they should not restart the machine after resetting. Guard or control should be of fail-safe type i.e. the machine will stop if the control fails. When there are more controls nearly placed or on one board clear instruction of their use must be marked to prevent then false operation. Locks or keys on some controls are required to prevent their undesired operation by mistake.

Safety by Precautions and Maintenance: Above paras highlight the need of utmost precautions in safe operation and maintenance of all safety guards, devices and controls. A man has made them and a man can make them ineffective or misuse. Therefore all precautionary operating measures are necessary in addition to the machine guarding. The machine operators should be made aware of hazards in their works, location and operation of machine controls, regular checking of guards, warning and training not to make the guards ineffective, repairs, adjustment etc., by specially trained person, need of wearing tight fitting clothing and protective equipment necessary and using right tools and equipment.

Criteria for Guard Selection : Selection of a guard depends on following factors :

1. Its physical dimensions, weight etc.
2. Method of drive and power requirements.
3. Limitations of speed, pressure, temperature etc.
4. Materials being processed or handled.
5. Access requirements especially for setting, adjustments and maintenance.
6. Environmental factors such as noise, vibration, dust, fumes and
7. Operating requirements such as visibility.

4.2 Built-in Safety Devices :

The object of built-in safety device is to design and make the machine, equipment, method and environment so safe that the workers' exposure- to accident or injury is eliminated or controlled automatically.

It is well experienced that many a times the guards provided on the machines are removed, not refitted and dangerous parts run without guards. Such unsafe practice leads to accidents. Therefore it is always essential to incorporate built-in safety devices (guards) from the design stage so that they become integral part of the machine and subsequent guarding is least required.

Built-in-safety can be designed for point of operation, transmission parts, controls, maintenance, adjustment and cleaning. Unnecessary projecting parts should be avoided. Risk at cutter, tool or equipment should be eliminated or minimised by design, enclosure, handle etc., closed tools are safer than open tools, controls should be in easy reach and inching or slow motion, braking, tripping, reversing etc. should be provided where necessary.

Benefits of Built-in Safety Devices :

1. They are more safe from accident prevention point of view.
2. They serve more than one purpose.
3. They are less costly in long run. Subsequent addition of guards requires frequent maintenance and they are usually more costly and less effective.
4. They provide better standard to the design and operation of the machine.
5. Need for training and supervision to control unsafe acts is reduced.
6. It helps for efficient production, high morale and less labour turnover.

For best results, planning at initial engineering level is necessary. Right from the-drawing and design stage to the delivery stage, all safety aspects should be built-in. The responsibility should also be extended to product design, machine design, plant layout and working conditions, selection and specification of materials, production planning, time study methods, duties of production foreman and the duties of the workers.

The disadvantage of built-in guards is that slight modification or unanticipated circumstances, after machine installation can render the guarding less effective. Therefore necessary correction in safety device should be made if such change is required.

4.3 Incidental Safety Devices and Methods :

Some incidental safety devices (indirect guards) equally useful as machine guarding are as below:

Two Hand control : Two push buttons are required to be operated simultaneously thus keeping the operator's hands engaged and away from the dangerous parts. Such device does not protect another approaching person, is prone to faults and cause difficulties on electrically, hydraulically or pneumatically powered machines. Therefore such device alone is not advisable. It is used on garment presses etc. Where two operators have to work simultaneously, four push buttons are required to keep their hands away from dangerous parts.

Optical Sensor : This uses photoelectric cell and a light. On interruption of light beam, the dangerous part is stopped. Its working must be checked before starting the work.

Electromagnetic Sensor : This uses a sensor of electromagnetic field, a coupler and interconnecting cable and a control unit. Interruption of the field by an operator's hand causes an electric signal which initiates the desired control action.

Mechanical Feed : A positioning device like conveyor or a rotating table moves the parts or material into the point of operation where the hazard exists thus avoiding human contact there.

Feed Tools : Tools viz. tong, magnetic lifting rod etc., are used to place material in a press with an intention to save the hand.

Pedal Guard : Such guard on foot-pedal of a power press prevents occidental foot-stroke on the pedal.

Ultrasonic device : Inaudible high-frequency sound senses the presence of any part in the danger zone. As sound attenuates over distance its application is limited.

Feed Hopper : It extends the feed length to prevent access. It can be used on pug mill, rubber mill etc.

4.4 Guarding of Different Machines :

Some statutory specific guarding is mentioned below under the Guiarat Factories Rules, 1963.

Textile Machinery (Rule 54, Sch. 1) :

Applicability: This schedule applies to machinery to manufacture or process of 'textile' i.e. cloth or fabric. It does not apply to 'Jute Textiles' or manufacture of 'Synthetic Fibres' i.e. yarn. This means it applies to manufacturing of cotton or synthetic cloths.

Definitions : 31 types of textile machines or their dangerous parts are defined. It includes opening, combing, carding, weaving and processing (bleaching, washing, printing, drying, sanforizing, shearing, cutting etc.) machinery. -

Machine Guarding : It is summarised in Table, 14.2

Table 14.2 : Guarding of textiles machines.

	Name of the Machine		Guard / Device Suggested
1	General requirements	1	Individual Starting/ Stopping device in safe position
		2	Belt shifting lock
		3	Guards on all moving parts
2	Openers/ Pickers	1	Interlock guards / doors on beaters and dangerous parts
		2	Feed guards
		3	Nip guards on fixed rolls and lap forming rollers
3	Cotton Cards	1	Interlocking doors on cylinders
		2	Fixed guard on licker-in
		4	Trained worker for stripping or grinding
4	Garnet Machines	1	Fixed guard on licker-ins
		2	Fixed guard on Fency rolls
		3	Screen under garnet
5	Gill Boxes	1	Guard on feed end
		2	Nip guards on rolls (Distances are suggested)
6	Silver/ Ribbon , lappers		Guard on calendar drums and lap spool
7	Speed Frames		Interlock doors on head stock gearing
8	Spinning Mules		Guard on carriage wheels
9	Slashers/ Dryers	1	Nip guards on in-running rolls
		2	Control levers within 1.7 mt from the floor

		3	Stop/ Start push buttons conveniently located
10	Looms	1	Shuttle guard
		2	Beam weigh fall preventer
11	Valve on Kiers	1	Locking device on valve
	Tanks & containers	2	Shut off valves to stop overflow/ splash
12	Shearing Machines		Guard on revolving blades (opening less than 1 cm)
13	Bleaching range		Nip guard on rolls
14	Mercerizing range	1	Stop button at each end of the machine
		2	Guard on frame between chain & clip opener
		3	Nip guard on mangle rolls & washers
15	Centri-fugal extractors	1	Interlock guard on basket
		2	Brake to stop basket
16	Mangles, Washers etc.		Nip guards on in-running rolls
17	Sanforizing and Palmer Machines	1	Nip guards on in-running rolls
		2	Side guards on in-running rolls
		3	Trip rod, cable or wire near cylinders. Height not more than 1.7 mt from working platform.
18	Rope washers	1	Splash guards
		2	Trip rod near washers
19	Washers, tumblers or shakers	1	Interlock door on cylinder
		2	Holding open device for cylinder doors
20	Printing machine	1	Nip guard on rolls
		2	Fixed guards on rollers, gears & wheel
		3	Fixed guards on rollers, gears & wheel
21	Calendars		Nip guard on rolls
22	Rotary staple cutter		Guard on cutting zone
23	Plating machine		Guard on space between knife and card bar
24	Hand baling machine		Handle stop guard at right angle to the frame
25	Flat work ironer		Trip bar/ guard on first pressure (feed) rolls to stop the machine.

Note : See chapter 21 for textile industry.

Ginning, Woodworking and Rubber m/c :

The machine guarding u/r 54, sch 2, 3 and 4 is summarised below in tale 14.3 :

Table 14.3 : Guarding of Ginning, wood working and rubber machines.

Machine		Dangerous Pars	Types of Guards
I Cotton Ginning (Sch. 2) :			
	Line shaft to run the gins	Line shaft	Wall or fencing with locking doors.
II Wood working			
1	Circular saws	The saw	A riving knife of prescribed dimensions and setting. Adjustable top guards, two metal plates guard, push sticks
2	Band Saws	Top and bottom pulleys and the blade	Fixed guards

3	Planning machine	Cutting slot, freed roller	Bridge guard, efficient guard
4	Vertical Spindle Moulding machine	Cutter, the wood being moulded	Suitable guard, A jig or holder
5	Chain mortising m/c	Chain and cutters	Suitable guard
III Rubber Mills (Sch. 4) :			
1	Rubber mill	Inrunning rolls	Height more than 96.5 cm, a distance guard, feed hopper, trip guard (rod) within 1.7 m height.
2	Calendar m/c	Inrunning rolls	Trip guard within 1.7 m height, tight wire cable connected with it.

Note : See Chapter 23 for specific industries.

Centrifugal Machines (Rule 54 Sch. 5) :

Applicability: This schedule applies to centrifugal extractors, separators and dryers but does not apply to similar machines of sugar manufacturing industry.

Requirements:

1. All parts of the machine shall be of good design, construction and adequate strength, properly maintained and examined thoroughly by a competent person at regular intervals.
2. Lid on cage housing, revolving drum or basket shall be strong and interlocked.
3. Effective braking arrangement is required to stop the drum/basket after the power is cut off.
4. Operating speed shall not exceed the rated speed which is stamped at visible places on the basket and the machine casing.

Power Press (Rule 54 Sch.6) :

Applicability : This schedule applies to all types of power presses including press brakes except when used for hot working of metal. The CIF can give exemption by a written certificate with conditions, if any, and he can revoke such certificate also.

Tower-Press' means a machine used in metal or other industries for moulding, pressing, blanking, raising, drawing and similar purposes.

Guarding of Tool & Die : Tool and die shall have a fixed guard so as to prevent hand injury in the danger zone. A small aperture shall be provided at the bottom of the die guard to feed the machine.

An automatic or interlocked guard may be used in place of a fixed guard but it should be maintained in efficient working condition and if such guard develops defect, the press shall not be operated till the defect is removed.

Trained person for testing, preparing etc. : To set, adjust, try out, install, inspect, test or prepare a tool or safety device on a power press, an adult trained worker shall be appointed and his name shall be entered in Form No. 8.

Testing by a Competent Person : No power press or safety device shall be used unless it has been thoroughly examined and tested by a competent person. Periodicity of testing for a power press and its safety devices is 12 and 6 months respectively.

Details of such test report are prescribed in para 6(4) of the schedule. This includes name and address of the factory, name of the occupier, identification number or mark to identify the press or safety device, date of, the first use, date of each examination and particulars of defects found and steps taken to remove them.

Disclosure of Defects & Measures : By any test > or examination, when any defect is disclosed by a competent person, the defective press or safety device shall not be used till it is remedied.

The competent person shall inform the occupier and the Inspector (within 14 days) in writing, the defect to be rectified. The defect shall be remedied and its record shall be kept stating the measures and the date of remedy.

Inspection & Test of Safety Device : After setting, resetting or adjustment of any tool, every safety device of the press shall be inspected and tested by the authorised (appointed) person and then only the press shall be used.

Defect disclosed in a safety device as above, shall be notified to the manager forthwith.

Identification: Every power press and every safety device on it shall be distinctively and plainly marked.

Training & Instruction to Operators : The operators shall be trained and instructed in the safe method of work before starting work on any power press. See fig. 14.8.

Shears, Slitters and Guillotine Machines (Rule 54 Sch. 7):

Guillotine machine has a straight or bevel edged blade and Shearing machine has a similar blade operating vertically, while Slitting machine has circular disc type knives for slitting into narrow strips.

These machines are used to cut metallic or non-metallic substances.

Machine Guarding:

1. The descending blade should have a fixed barrier guard in front of the blade (knife) fitted with the machine frame.
2. Where fixed guard is not possible due to size and thickness of the material being fed, either 'two hand control' or 'push away' device shall be provided for the protection of hands.
3. At the back end, inclined ducting cum guard shall be provided through which the slit pieces would slide and be collected at a safe distance and which would prevent a person from reaching the blade.
4. Except continuous feed trimmers, power driven cutters shall have two-hand starting device (push buttons) and at least one hand on a control during the completion of the stroke. In addition to the brake (stop device), an emergency device shall be provided to prevent the machine from operating in the event of failure of the brake.
5. An automatic guard to push away the hands at every descent of the blade. (Such guard may be preferred as a last resort if other devices are not possible).
6. Where more than one worker work on the same machine, two-hand start device should be for each worker and at least one hand on a control to complete the cut.
7. Circular disc type knives shall have a fixed or manually or automatically adjustable guard to enclose the knife edges. The space between the guard and the material should be less than 6 mm. Portion underneath the table should also be guarded.

Mechanical power press and its machine guarding are shawn in fig. 14.8.

Dangerous Machines : The substituted Rule 57, prescribes the following machines as 'dangerous' and no young person (below the age of 18) shall work on it-

1. Hoists, lifts, lifting machines, chains, ropes, lifting tackles and revolving machinery (Sections - 28,29,30).
2. Power presses other than hydraulic presses.
3. Milling machines.
4. Guillotine machines.
5. Circular Saws.
6. Platen printing machines.

Other guarding is explained in respective Chapters 20 to 23.

5 MATERIALS FOR GUARD CONSTRUCTION

Generally metal is preferred for machine guard construction. Bar, pipe and rod are used for structural frame. Filler material may be solid, perforated or expanded sheet metal or wire mesh. Opening in wire mesh should be as minimum as possible as shawn in fig. 14.7. Where transparency is necessary plastic or glass material can be used. Safety glass and plastics are also used to protect against flying particles and chips.

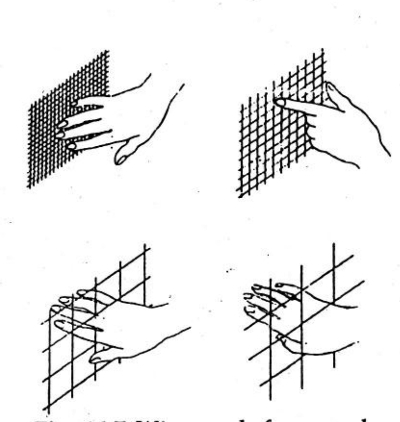

Fig. 14.7 Wire mesh for guard.

Wood guards have limited application due to their poor strength and durability, flammability and high maintenance cost.

Aluminium guards are preferred where rusting or damage to tools or machinery are considerable.

Plastic guards are used where inspection of the moving parts is necessary. Safety glass and plastic used where chips or other flying particles are likely to mar the surface should be protected by replaceable cover glasses.

Whatever material may be selected for guard, it must be sound and durable to withstand impacts, vibrations and other forces.

A floor guard becomes necessary in addition to the enclosure guard to prevent vehicles from straying into the hazard area such as guards on aisles or roadside.

Materials to reduce noise :

Guards are provided near the point of operation and near the transmission of power i.e. near the source of noise. Guards are subjected to vibrations also. Therefore they can make noise. Therefore the guards should be designed as a barrier against noise in addition to a barrier against injury. A common way to absorb sound is to cover the guard frame with sound absorbing material. A gasket type material can be used around the edges to avoid metal to metal contact and noise generation due to it. The guard should be secured with shockproof fittings. Such type of material and proper fitting will reduce the conducted noise. This will be an extra benefit of the guard.

Non-metallic (e.g. plastic) machine parts (e.g. gears) and guards can also reduce the noise.

Well maintenance and lubrication can also reduce the noise.

6 ERGONOMICS OF MACHINE GUARDING

6.1 Meaning of Ergonomics :

As explained by W.T. Singleton in ILO Encyclopaedia, literal meaning of 'ergonomics' is the study, measurement and organisation of work. It is concerned with making purposeful human activities more effective. The focus of study is the person interacting with the engineering environment. The designer should consider complexity arising from human nature and his limitations. To consider human factors, it studies anatomy, anthropometry, biomechanics and psychology as useful sciences. To consider design aspect of work, systems, workspace, environment, interface and work situation, it studies technology. Thus an ergonomist is expected to take an over-all view and identify the key design aspects for particular people engaged in particular tasks.

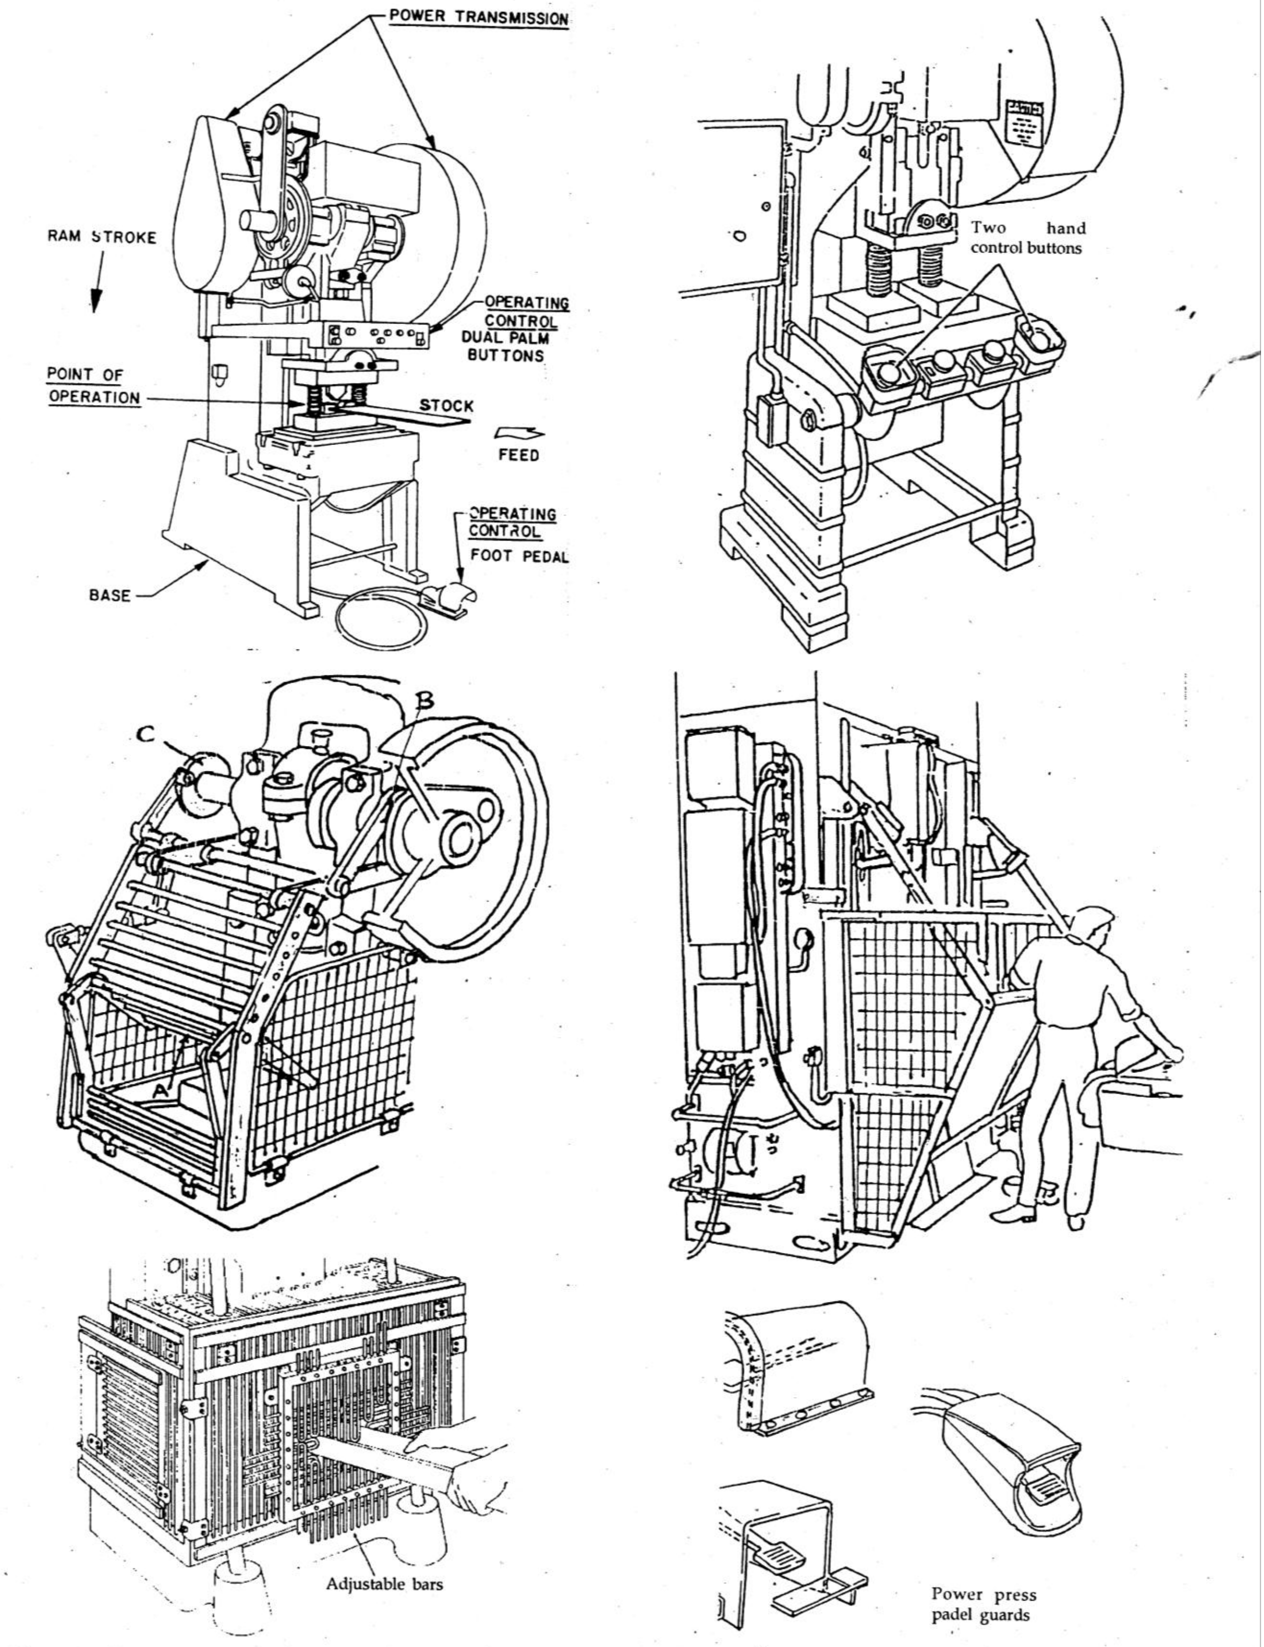

Fig. 14.8 Power press machine guarding.

As explained by K. Kogi, a Regional Advisor to ILO, ergonomics is a useful tool for fitting work to people, not people to work. 'Ergon' means work and 'nomos' means habit of law. Thus ergonomics is for the purpose of solving the problems of work habits. It requires designing of proper workspace, working posture, reach, seat, controls, knob, brake, display, communication, skills, work intensity; sufficient time for rest, good environment, clear understanding and providing platforms or lift tables, carts, transport ways, proper storage racks, buffer stocks, good lighting, ventilation and housekeeping, proper guards and good welfare facilities. Thus ergonomic principles include comfortable posture, balanced and easy motions, adequate rest and enough variety.

As a science, ergonomics studies anatomy, physiology and psychology. Anatomy includes anthropometry and biomechanics. Anthropometry, the measurement of man provides the dimensional data needed for the positioning of controls and the size of work spaces. Statute (height upto head), eye height, shoulder height, elbow height, knuckle height (upto the palm of hanging hand), sitting height, shoulder width, breadth across elbows, upward reach, sideways reach, forward reach, hand length, hand breadth etc., are main human dimensions as stated by W.T. Singleton. Biomechanics is concerned with the application of forces by the human body. This requires knowledge of the locations of the main muscle groups, their composition and their modes of action.

Physiology includes work physiology & environmental physiology. Work Physiology is concerned with the human process of energy production & considers human efficiency, oxygen uptake capacity etc. Environmental physiology provides measures of the stress and standards of reasonable parameters of climate, light, noise, vibration etc. Their effects on human behaviour are studied.

Psychology considers various factors described in Chapter-3 and also some theories such as human performance theory based on an information model of the human operator, learning and skill theory and training and organisation theory for work and system designs. Such psychological theories say about human error - why people make mistakes. Many times guards, controls and protective equipment are provided but operators fail to use them. Why do they do so is an important question which can be replied by psychological study only. Effective audio-visual information, choice reaction times, information processing capacity, memory, attention, understanding, fatigue effects, interaction with other people, morale, group behaviour etc. are useful factors to be considered. If workers are properly educated and trained based on such study, their failure to use guards and safe job methods will be minimised. Such human factors must be considered while designing any machine or work.

Explaining the historical part. King and Magid state in their book (Ref. No. 4 at the end of this Chapter) that this word was first used in 1949 when the society, the Ergonomics Research Society was founded in Britain including anatomists, physiologists, psychologists, industrial medical officers, industrial hygienists, design engineers, work study engineers, architects, illuminating engineers and others. In USA the terms 'Human Engineerings and 'Human Factors Engineerings are used to cover the same field. Biomechanics and Engineering Psychology are other expressions used.

See Part 2 of Chapter-24 for further details.

6.2 Aims of Ergonomics :

Its aims are :

1. To facilitate whatever a person wishes to do and to ensure that he does it comfortably and efficiently. Efficiency includes effective work without detrimental health effects and minimisation of risk to the operator and others.

2. The work, working conditions, plant and infrastructure should be so designed that they are best fitting to the workers. Purpose is not to fit a worker to any awkward, unsafe, unhealthy or uncomfortable work. But the purpose is to design or provide work and working conditions comfortable to the workers.

3. To minimise the possibility of human error or mistake. To ensure industrial activities with minimal use of energy and materials and without waste resulting from mistakes.

4. To develop knowledge and techniques by the combined use of many expertise and systems approach.

5. To solve human problems of work performance by considering human factors in design of machines and work and safe job methods which are explained in the following part.

6.3 Human Factors in Design of Machine and Work:

Technology has changed the people's ways of working but the people are not changed much. Many times the people do not adapt physically and mentally, a tendency of modern work methods. This generates negative reactions which also indicate human factors to be considered by the ergonomists while designing work and machines. Some such factors are :

1. Increased stress.
2. Uninterested work.
3. Errors and accidents.
4. Work related diseases.
5. Awkward body position causing difficulty.
6. Repetitive tasks producing boredom and tiredness.
7. Confusing signals causing human errors in hurry.
8. Bent or awkward posture while handling heavy materials and causing back pain.
9. Perceptual limitation.
10. Short term memory.
11. Incompatibility in man-machine relationship.
12. Risk or chance taking.
13. Position or location not suitable to a worker such as unsuitable work height, seat, layout of control and displays.
14. Organisation of heavy work.
15. Environment.

It may not be possible to incorporate all these factors in machine or work design. Administrative measures, safety training, signs and signals, work scheduling, supervisory observation, plant layout, psychological and medical measures and workers' cooperation may also benecessary.

7 MAINTENANCE AND REPAIRS OF GUARDS

Section 21 of the Factories Act states that the guards shall be constantly maintained and kept in position. Such maintenance is obviously necessary because a machine running without guards or with open or broken guards pose danger. Regular inspection of guards can detect the guard removed, damaged or requiring repairs. A guard removed for repair should be fitted at the earliest possible and meanwhile temporary guard should be installed or the machine be stopped. Good maintenance increases the life of guards and vice versa. The supervisor should pay constant attention for this.

A guard should be so designed or fitted that it is not to be opened for oiling/greasing or nearby maintenance work. The parts needing regular service should be located outside the guard. If oil/grease fittings are inside the guard, an extension through the guard should be provided.

Automatic controls for lubrication, adjustment or service can be provided by a sophisticated equipment. Interlock type guard ensures that the machine cannot be operated unless all guards are in position. Such planning helps maintenance without disturbing guards.

When a guard cannot be made to exclude lint, fume, dusting etc., extra ventilation should be provided. Large guards should have self-closing doors for cleaning. Space should be provided in surrounding for repair and maintenance. Some people use red colour for guards to show dangerous part while some prefer the same colour that of the machine to consider it as an integral part of the machine.

Work on machinery in motion for maintenance purpose :

During maintenance of a machine, normally a guard is removed and observation for fault, alignment, repairing or oiling/greasing is carried out in unguarded condition. Such condition may kill or injure' an untrained or unknowing person. See foregoing Part 1.2, para 'Work on or near machinery in motion' for statutory requirement u/s 22 of the Factories Act.

Zero Mechanical State (ZMS) :

As far as possible this. state (condition) should be observed i.e. all energy sources must be de-energized or made least effective before any maintenance work is to be started. After switching off electrical power, rotating machinery may continue to rotate due to moment of enertia. This may cause accident. The rotating part should come to rest i.e. in stop condition. Therefore mechanical steady state condition (ZMS) should be maintained before starting any maintenance work. This is the safest condition.

Lockout and Tag-out :

This system is used at the time of maintanence or repair work on machine. Power source to the machine is cut off or it is mechanically locked. This is called lockout. A tag is tied with necessary instruction that this machine is under repair or maintenance audit should not be started. This is called tag-out.

For detail see part 6.2.9 of Chapter - II.

E X E R C I S E

1. Explain, State, Mention or Discuss :

1. The basic need and importance of machine guarding.
2. The following terms :
   (1) Prime mover (2) Machinery (3) Power (4) Self acting machines (5) Revolving machinery (6) ZMS (7) Point of operation (8) Safety by position (9) Built in care (10) Trip guard (II) Feed tools (12) Two hands control (13) Crown guard
3. The contents of a 'Machine Safety Checklist' as given by NSC, USA.
4. The groups of dangerous parts according to motions OR According to H. A. Hepburn.
5. Characteristics of a machine guard.
6. Principles of ergonomics for machine guarding.
7. Human factors in design of machine and work.
8. Classification of machine guards.

9. Types of fixed guards OR Types of Interlock guards.
10. Different types of Incidental safety devices.
11. Machine guarding for Centrifugal machines OR Power presses.
12. Machine guarding for shears and slitters.
13. Methods of Maintenance and Repairs of guards.
14. General principles of good guarding practice.
15. The effects and acceptability of machine guards.
16. Main mechanical hazards in engineering operations.
17. The restrictions of employment of workers on specified machines and conditions under which the restrictions are relaxed.
18. Methods of eliminating potential hazards from the job.
19. What type of guard would you suggest for (1) Disintegrating machine (2) Rubber mill rollers (3) Open end of a rotating shaft at low height (4) Overhead shaft and pulleys at a height of 10 ft. (5) Basket of a hydro extractor (6) Straw-board calendar machine (7) Cylinder of a carding machine (8) Lap forming rollers (9) Shuttle of a power loom (10) Rolls of a .drying range (II) Jigger machine for dyeing a cloth (12) Mangles of a washing machine (13) Press rolls of a paper mill (14) Rope washers (15) Rotary staple cutter (16) Hand baling machine (17) Band saw (18) Drill tool.
20. What points you will incorporate in placing an order requiring a lathe or shaping machine?

2. Write short notes on :

1. Fencing of machinery (sec. 21, F.A)
2. Work on or near machinery in motion (sec. 22, F.A)
3. Striking gear and devices for cutting of power.
4. Basic steps to prevent accidents.
5. Dangerous parts of rotary motion OR Reciprocating motion and its examples.
6. In-running nips.
7. Human factors engineering.
8. Aims of ergonomics.
9. Criteria for guard selection.
10. Benefits of built-in safety devices.
11. Machine guards for textile machines OR Wood working machines.
12. Testing of dangerous machines by a Competent person.
13. Types of dangerous machines.
14. Materials for guard construction OR Materials to reduce noise.
15. Guarding during maintenance.
16. Quality of guards.
17. Design principles of machine, guards.
18. Safety points while operating a grinding machine OR Centrifuge machine.
19. Machine guarding for rubber mill industry.
20. Advantages of built in guards.
21. Safety points for working on a grinding machine.
22. Types of point of operation guards.
23. Formula for maximum safe opening in a point of operation guard.

3. Explain the Different between (give examples)

1. Machinery & Transmission machinery.
2. Power & Prime mover.
3. Guarding & Fencing.
4. Built in guard & Safety devices.
5. Safety by construction & Safety by position.
6. Interlock guards and Automatic guards.

7. Mechanical interlocking and Electrical interlocking.
8. Safety by Machine controls and Incidental Safety devices.
9. Built in safety devices and Incidental safety devices. ,
10. Control guard and Interlock guard.
11. Push buttons and push away guard.
12. Circular saw and Slitting cutter.
13. Home made guards and Guards made by manufacturer.

4. Comment on the Following explaining whether it is true or not -

1. "Safe by fencing" and "safe by position" is one and the same.
2. Fit work to workers and not workers to the work.
3. Accidents take place due to bad maintenance of machines.
4. Belt hangers are required on overhead shafts.

CHAPTER – 15

Material Handling

THEME

1 NEED OF SAFETY IN MATERIAL HANDLING

Material handling is the preparation, placing and positioning of materials to facilitate their movement or storage. In many industries, handling of materials, articles, equipment etc. becomes a main source of injury.

Without handling any material, no production is possible. Lifting, transporting and handling materials, manually or mechanically, is an age-old practice. In Chapter I explaining the Vedic definition of nation, it is stated that enough load carrying vehicles was one of the requirement. In Chapter 7, attention is drawn toward our Indian structures and architecture on mountains and elsewhere, which are the best examples of our ancient techniques of materials lifting, carrying and handling.

Table 5.8 in Chapter-5 states that in India in the year 1990, 12.94% accidents were due to handling goods or articles. This figure was 15.29% in 1991. If accidents due to falling bodies and due to hand tools are added, total 30.31% can be said due to materials and tools handling. From table 5.22 in Chapter-5, it is inferred that total accidents of 1994 in Gujarat due to lifting machine, hand tools, struck by falling bodies and handling goods or articles (total of causation No. 104, 124, 125 and 130 in the last row) were 2686 out of 15683 i.e. 17.12%. This concludes that nearly 18% accidents are caused by material handling.

Studies carried out by the Central Labour Institute, Mumbai, also show that the percentage of accidents caused by material handling in textile, engineering and foundry factories were 16.7%, 23% and 27.7% respectively.

An old Anglo-American Productivity Report says that material handling accounts for 36% of production costs, 50 to 100 tonnes of materials have to be handled for every tonne of finished products and about 2/3 of the' manufacturing time cycle is spent on material handling. Thus its coverage is very wide causing more accidents to men, materials and equipment which ultimately decreases the productivity. Therefore it is rightly said that material handling does not add to the value of the product, but adds to the cost of the product. Therefore to prevent human injuries, material loss, money loss and time loss, accidents due to material handling must be prevented.

Material handling is of two types; manual and mechanical. To avoid unsafe acts and other hazards like slipping, falling, striking etc. in manual handling, it is being substituted by more and more mechanical handling. It reduces such hazards and manpower, and increases productivity.

Hazards of manual handling are due to :

1. Carrying excessive load.
2. Lifting improperly.
3. Unsafe gripping or placing.
4. Struck by falling body or striking against object.
5. Person falling or slipping.
6. Failure to wear PPE.

Hazards of mechanical handling are due to

1. Wrong selection of equipment.
2. Design defect or unsafe construction or operation of equipment.
3. Overloading of equipment
4. Wrong position of material or equipment.
5. Working at excessive speed.
6. Lack of space for operation.
7. Lack of skill, training and correct attitude on the part of operator.
8. Improperly guarded or unguarded machinery.
9. Electrical faults and
10. Poor maintenance or no testing.

Accidents can be avoided by good training and supervision, periodical examination of equipment and medical examination of workers. To study material handling problem, safety professionals should study

1. Possibility of eliminating or reducing manual handling or its defects.
2. Possibility of mechanical handling.
3. In what ways injury possible? .
4. Handling aids-hooks, trucks, trolley boxes - to make the job safer.
5. Protective equipment or clothing to help prevent injuries.
6. Need of training to workers

2 MANUAL HANDLING

2.1 Statutory Provisions :

Maximum Liftable Loads:

Person	Permissible Max. Weight (Kg)
Adult male	50
Adult Female	30
Adolescent male	30
Adolescent female	20
Male child	16
Female child	13
Two adult workers working together for carrying load by handcart	500

Rule 62 of the Gujarat Factories Rules prescribes the following maximum loads that could be manually carried or lifted (Notification dated 7-6-2001)

Rule 38 of the Building and other Construction Workers Central Rules, 1998 also prescribes the same limits for building workers. See Part 7.2 of Chapter-28.

It is also clarified that no adult male, adult woman, adolescent or child shall engage, in conjunction with others in lifting, carrying or moving by hand or on head, any material, article, tool or appliance if the weight thereof exceeds the lowest weight fixed by the above table for any of the persons engaged multiplied by the number of persons engaged. Thus two male children cannot be engaged to lift mdre than 16 x 2 = 32 Kg, five adolescent females cannot be engaged to lift more than 20 x 5 = 100 Kg and so on. Actually this should be still less considering 'coordination losses'.

However, it is true that looking to the variety of differences in persons of the same age and same sax, they differ in their capabilities. Personal and climatic factors also have effect (e.g. heat stress, cold stress, discomfort etc) on them of the same age and sex, different persons can lift different amounts of weight because of their body built, practice, height, weight structure etc. Work load condition, shape, size (job safety analysis) and personal health should also be considered in deciding lifting standards.

Nevertheless, from safety and legal point of view, it is necessary to prescribe some reasonable safe limits based on scientific criteria. Otherwise exploitation of workers requiring them to lift any amount of load is possible. This may result in accidents, injuries, absenteeism and leaving the job.

2.2 Indian Standards :

While handling materials manually, personal protective equipment for various body parts are necessary as per requirement. See Part 3 of Chapter 25. Still a few IS are mentioned below :

Leather for leg guards 3946, for garments 12718, leather shoes, non-slip, oil resistant rubber soles 11543, leg and foot safety equipment selection 6519, 10667, Gloves - disposable 7180, chrome leather 5866, leather gauntlets and mittens 2573, rubber - surgical 4148, post-mortem 4149, safety industrial 6994; Gloves and mitts, insulating materials for live working 13774, Electrical purpose rubber gloves 4770, Rubber aprons 4501, Safety equipment for arms and hands 8807.

Guide for selection of body protection 8519, Safety belt and harnesses 3521, Protective leather clothing 6153, Eye protectors 5983, Face shields 8521, Leather safety boots and shoes 1989, Protective gaiters 2472, footwear for steel plant 10348, PVC boots 13038, 13292.

Safety helmet 2925, Respirators glossary 8347, Selection, use and maintenance 9623. Breathing apparatus 10245. Life jackets 6685.

2.3 Kinetics of Manual Handling :

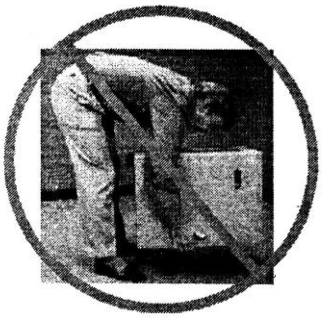
In manual material handling human body acts as a machine (lever mechanism) and undergoes forces and torque. Therefore stress and strain occur and if work goes beyond one's capacity, pain, fatigue or injury results.

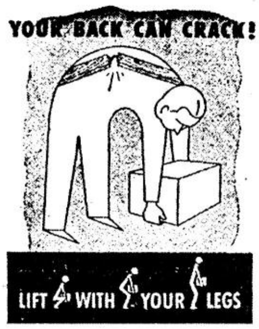
Types of adverse effects or injuries associated with manual material handling are strain, sprain, back pain, cuts, bruises, burns, fracture and non traumatic injuries occurring after a long time.

Therefore it needs to understand kinetics of manual material handling. Lifting and carrying exert strains to the body. The body can be kept erect only by tensing muscles. Even while walking on slopes or stairs, considerable effort is required. '

Carrying load imposes a static strain on muscles of arms and trunk and also on back and heart. Muscles are also engaged while holding the load and cause fatigue. Serious fatigue results in reduced output and may cause accident.

Clinical investigations carried out by Schroter on groups of manual handling workers and office workers shown effects on skeletal system such as in the spine elbow joints, knee joints etc. While lifting load, lumber discs are affected much.





The lifting system of the spine can be represented as a double armed lever arrangement in which the force of the back muscles is applied to the ends of the spinous process, which are about 5 cm long. According to the principles of levers, the force exerted by the back muscles must be 8 or more times the resistance represented by the load. The strain borne by the disc exceeds that exerted by the back muscles by an amount equal to the weight of the load. It has been noticed that on men between 20 to 35 years, a disc stress of over 30 kg/ m2 can be damaging.

Lifting lighter loads with jerks is also harmful and may cause spinal pain.

2.4 Safe Methods of Lifting and Handling :

They are necessary to minimise physiological stress and accidents while handling materials of different size and shapes.

2.4.1 Avoidance of Excessive Muscular Efforts

Adverse effects due to manual handling are explained in brief in Part 2.3.

Careless or wrong manual load handling causes injury to the spinal column and adjacent muscles, particularly the lumber region. It may also cause pulse rate rise, blood pressure rise, brain haemorrhage, abdominal hernia, back pain and ptosis of abdominal organs. When excessive loads are regularly carried from an early age, the constant stress and strain on

muscles, ligaments, joints and bones can cause deformities such as scoliosis or kyphosis in the vertebrae, damage to the arch of the foot and inflammatory and painful conditions of the muscles and bourse. Constant pressure on the skin, muscles or nerves leads to callosities, neutric pains or paralysis, hypertrophy, back trouble, heart enlargement, hardening of the blood vessels and hypertension. Women are much affected than men and in children it may affect bodily (skeletal) growth. Therefore avoidance of excessive muscular efforts is utmost necessary.

Wrong handling

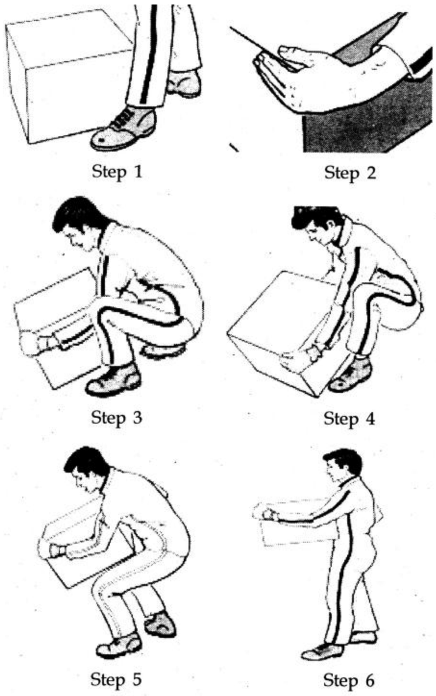
Back pain due to manual handling results in absenteeism. Lundgren questioned 1200 Swedish workers who had been absent because of back trouble. Those engaged in heavy work reported more absenteeism from back complaints as those employed in light work. Kramer has estimated that overall 20% of all absenteeism is caused by injury to discs and this account for half of all premature retirements. Further research (Davis and Stubbs) has shown a close relationship between forces acting on the lower back and pressures generated in the abdominal cavity. They have found 'that the workers whose abdominal pressure was found in excess of 100 mm of Hg, had significantly high incidences of back pain.

Based upon observations on some 700 British male subjects, a guide was issued by the Material Handling Research Unit, University of Surrey which gave force limits for lifting, pulling and thrusting. By using this guide, work practices can. be designed so as not to exceed the maximum limiting intra-abdominal pressure, 90 mm of Hg and thus indirectly reduce the possibility of back pain.

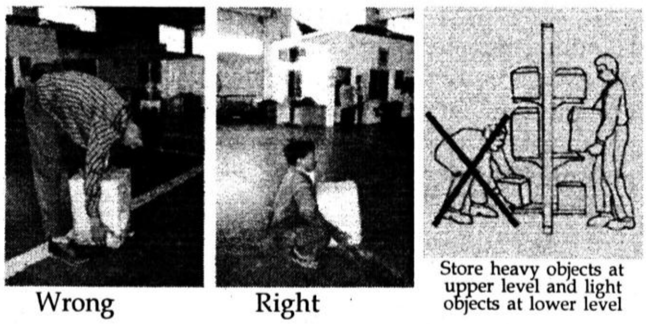
Age and sex affects .the efficiency. After the age of 30 efficiency declines. Women have weaker muscle power than men and are shorter in height. Hence their reach is less and the maximum physical capacity of a woman is about 2/3 of a man's.

Steps of Kinetic Method of Lifting are :

1. One foot ahead of the other in the direction of the movement.
2. Grasp the load from the palm and not from the root of the finger
3. Keep back straight, not necessarily vertical.
4. Keep the load close to the body.
5. Start lifting with the thrust of the rear foot, keeping the object close to your body as you lift with your legs, not with your back.
6. Keep the head in correct position. It is also necessary to keep the centre of gravity of the load as near as possible.



Safe method of Lifting :



1. The feet should be placed close to the load and properly spaced for body balance.
2. Back straight and as nearly vertical as possible. Elbows as straight as possible. Knees bent until the hands reach the proper place for gripping the load.
3. Grasp the load firmly. Lift should be completed by straightening the knees, keeping the load close to the body.
4. While putting down the load, above procedure should be reversed. .
5. Banding upto ground level should be avoided. , Support at hip level (3 to 4 ft.) is necessary.

Safety precautions while Manual Handling :

1. Movement should be in horizontal plane. Push and pull is preferable than lift or lower. Before lifting, the distance to be travelled and the time of grip should be considered.
2. Lifting or lowering should be between knuckle (hip) height and Shoulder height, it should be close to and in front the body. Bending or twisting of body causes overexertion injuries.
3. Material should be light, compact and safe to grasp. It should not have sharp edges, corners or pinch points.
4. Material from bin or container should be easily removable. The operator needs not to dive into the container to reach the material. Containers of chemicals should be properly closed.
5. If load is too heavy, use mechanical lifting device or take help from somebody.
6. Get the load close to the body and feet also close to the body. Stand in a stable position with the feet pointing in the direction of movement. Lift mostly by straightening the legs.
7. Temperature of the material, floor and work area. should be comfortable. The floor should not be slippery.
8. Use proper hand, eye, leg protection and respirator if necessary.
9. Keep hands free from oil and grease. Clean the material if it is slippery or dirty.
10. Handle with firm grip. Keep fingers away from pinch and shear points.
11. Don't lift or lower awkwardly or by twisting the back or bending sideways or by extending the arms. Don't continue if the load is too heavy.

Workers should be trained for correct manual handling. They should know the weight to be lifted, position of centre of gravity, their capacity to lift, distance to be carried, physical hazards of the material such as sharp edges, size, brittle, slipperiness, greasiness etc., PPE necessary and chemical hazards including temperature and health effects.

Team Work in Lifting : When the load is beyond one man's capacity, more persons are engaged. Then the team workers should ensure that the load is within their total capacity. Team workers should be nearly equal in height, size and physique and the lifting should be done simultaneously. If necessary, one should act as a leader or signalman to guide others.

Long sections should be supported on the same shoulders (with shoulder pads) and walking should be done in step. It should be noted that the total load that can be lifted is not the sum of each person's capacity. J.F. Dashiel (1935)'s study had noticed coordination loss in team work as it is unlikely that each person in the team would exert his maximum force exactly at the same time. Hence if one person can lift 55 Kg, two persons can lift 100 Kg (not 110 Kg), three persons can lift 140 Kg (not 165 Kg), six persons can lift 210 Kg (not 330 Kg) and so on. But this cannot be always so, as motivation can change the situation, their minds are concentrated on some word or slogan or their efforts are properly united.

2.4.2 Lifting and Carrying of Different Objects :

Their methods are briefly as follows :

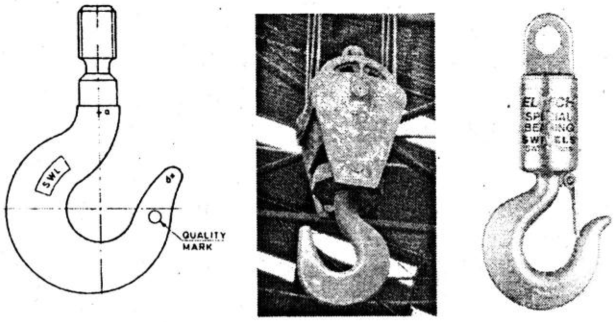
1. **Boxes and Cartons :** Grasp .them at opposite top and. bottom corners. Draw a comer between legs.
2. **Barrels and Drums :** Two men stand on opposite side. Grasp both chimes near the high point - up and while pressing down the bottom and straighten up with the drum.

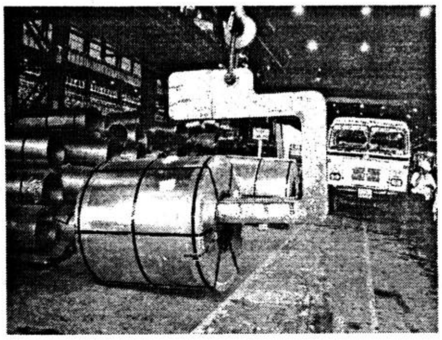
   Handling on incline - Use ropes and tackles. To control motion, pass a rope around a drum. One end of the rope should be fastened to the platform at higher level. A worker keeps a firm grip on the free end, then gradually lower or raise the drum along the risers.
3. **Sheet Metal :** Handle with leather gloves, hand leathers or gloves with metal inserts because of sharp edges and corners.
4. **Sheet Glass :** Handle with gloves or hand leather. Cover wrists and forearms with long leather sleeves. Leathers, or canvas apron and guards for feet and ankles should be worn. Carry the glass sheet with the bottom edge resting in a palm turned outward and with die other hand holding the top edge to steady it or balance it. Never carry glass sheet under the arm because fall might sever an artery.
5. **Long Objects :** Long pipes, barstock, lumber should be carried over the shoulders, with the front end held as high as possible to prevent striking. Other employee should guide when going around corners.
6. **Irregular objects :** If it is difficult to handle because of its shape or weight, assistance should be given.
7. **Metal Scrap :** Wear goggles, gloves or hand leathers, safety shoes and skin guards. Workers should be cautioned against tripping or slipping on objects which may roll or slide under feet. Mechanical handling of this commodity (magnetic lift crane) is preferable.

Heavy machines, round, flat objects etc. need specially trained workers. Specially designed truck, trolley or device is required.

2.5 Safe Use of Accessories for Manual Handling :

Each tool or other device should be kept in good repair and used for the job for which it is designed.



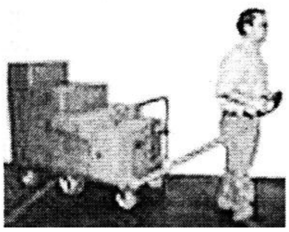


(1) **Hooks :** Danger of glancing off hard objects. When carried in a belt, the point should be covered. Sharp point necessary for handling bags, logs, crates, boxes etc. should be protected.

(2) **Crow Bar :** Main hazard is slipping. Point or edge should have a good bite. Proper position of hand and body to minimise chances of hand pinching or worker falling if the bar slips. Never work astride a crow bar. When not in use, keep on a rack.

(3) **Rollers :** Heavy or bulky objects are often moved on the rollers. Main hazard is fingers or toes getting pinched or crushed between the roller and the floor or the roller and the object, when the direction of the roller is changed. To move a roller under load, use a sledge or a bar, never hand or foot.

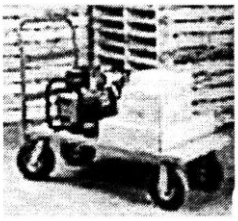
(4) **Hand truck and wheel barrow :**
It has mostly 4 or more wheels.



1. Knuckle guards to protect jamming of hands against door frames or other obstructions.
2. Wheel should be under the truck if possible to save injuries to toes and feet. Wheel guards are preferable.
3. Provide brakes to avoid holding a truck with a foot on wheel or axle.
4. Inspect daily and keep in good repair.
5. No one truck is right for handling all types of material. Select appropriate one.
6. Loaders should keep their feet clear of wheels. Load should be so placed that it will not shift, fall off or block clear view ahead.
7. On two wheelers, centre of gravity of load should be placed well forward.
8. Four-wheelers should be pushed and not pulled.
9. Avoid collisions especially at blind corners. Use mirror at corner.

10. Do not. park trucks in aisle ways so as to obstruct traffic or causing stumbling hazards.

(5) Hand Trolley:

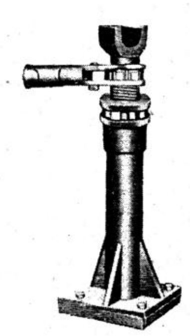


It has mostly 3 to 4 wheels.

1. Cover floor holes or remove bumps and make it even to prevent trolley from jumping.
2. Provide rubber tyres on wheels to minimise noise and damage to flooring.
3. Load should be evenly distributed to prevent tilting.
4. Don't overload trolleys. It is unsafe.
5. Load height on trolley should not obstruct vision.
6. Secure load on trolleys with ropes, stay blocks etc. wherever necessary.
7. While going up on slope, pull up the trolley and while going down on the slope push down the trolley.
8. Trolley handles should be held at the front artd not on the sides to avoid knuckles getting bruised due to contact with wall or machine etc. If the trolley handles are to be held on sides, provide knuckle guards.
9. Pathways should be clearly marked in white or coloured lines.
10. Park trolleys in such a way that they do not obstruct passageways.

(6) Jack:

An identifying plate showing lifting capacity should be visible. It should be painted or marked on it and never be exceeded. If hydraulic fluid leaks, that jack should be removed from use. Jacks should be lubricated only at points required. They should not be thrown or dropped. The resting floor should be checked for load bearing capacity and level. A hard wood insert should be used between the jack head and the load to avoid metal to metal contact. After the load is raised, metal or heavy wooden stands should be placed under it for support and risk of lack slipping or falling. To raise a large sized load, two or more jacks should be used, but they should be equally raised. Workers should wear safety shoes. Oil spiUage should be cleaned before and after the work.



2.6 Storage and Handling of Materials:

Floor conditions and safety in storage, loading and unloading are important.

2.6.1 Safety in Storage of Materials:

1. **Bagged Materials :** Cross ties with mouths inside. When pile is five feet high, step back by one row for each additional three feet. Do not remove a bag from a lower row first Prevent fire risks.
2. **Pipe and Bar Stock :** Consider strength of the floor. Pile in layers with strips of wood or iron between layers. Strips should have block at one end or one end turned up. Bar steel stock would be stored in racks inclining towards the back to prevent rolling. The stack height should be limited to 2 mt. Buttons should be placed between tire of bundles to facilitate slinging. Heavier bars should rest on rollers. Light bars may be stored vertically in a rack.

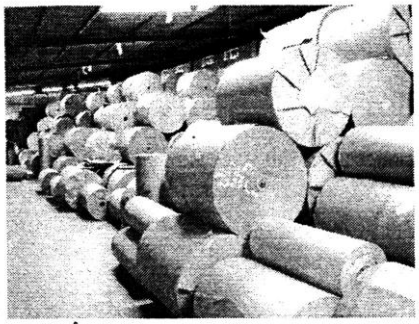
3. **Barrels and Drums** :- Pyramid shape is safe Bottom row should blocked when stacked on sides. If piled on ends. i.e. up right, planks

should be laid between rows. Strength of the drum, its size, shape and weight should also be considered.

4. **Metal Sheets and Plates :** If the sheets are i bundles and of fairly standard size, they can be safely stacked upto 2 mt height with buttons between each bundle. Sheets of random size should be stored in toast racking form. Heavy steel plates of more than 4 feet width should be laid horizontally. With plates of varying sizes, the largest ones should be at the bottom and the smallest on the top. Use leather gloves or gloves with metal inserts to hold sharp edges and corners.

5. **Long Objects :** A pile of lumber (bamboo, timber) should not be more than 20 feet high. Tie pieces are needed not only to stabilise the pile but also to provide air circulation. These pieces should not extent much into gangways.

6. **Cartons :** Loaded cartons should be stored on platforms or shelves to protect against moisture or breakage. When the sides are of unequal size, the tires should be so laid as to give natural bonding and provide stability. If natural bonding is not possible provide artificial bonding by a sheet or a wrapping paper placed between two layers.



7. **Paper Reels :** Fork lift can be used to store reels on ends. For stacking on ends, a well leveled floor is essential and the reels should be of the same diameter. Reels may be stored in horizontal position in nesting tires. Then the first or bottom row should be blocked to prevent the rolls from shifting.

8. **Liquid Chemicals :** Portable containers such as drums, barrels and carboys should be stored and handled carefully. Store room should have impervious walls and floors and provision for safe disposal of spillage. Before handling, check corrosion of nails or weakening of packing by the chemical. For transporting carboys use a carboy trolley. Safe way to empty a carboy is to move liquid by suction from vacuum pump or start the siphon by means of rubber bulb. Properly designed carboy inclinators are also satisfactory. Before piling empty carboys should be thoroughly drained and stoppers replaced.

9. Gas Cylinders:

1. Cylinders may be rolled on the bottom edge but never dragged.
2. Carry cylinder in a cradle or in a suitable type of carrying device.

3. Do not permit them to strike each other violently. Tie vertical cylinder by chain.
4. While returning empty cylinders or when not in use, close the valve and replace valve protection cap.
5. Always consider cylinders as full and handle them with care. Do not store gas cylinders in the sun or excess heat.
6. Follow the Gas Cylinder Rules 2004, IS:5903 and other Indian Standards.

10. Handling of Hazardous Material / Dangerous Substances/Chemicals:

USA Code (Title 49, Code of Federal Regulations) defines hazardous material as "Any substance which has been determined to be capable of imposing an unreasonable risk to person or property". It further states that "No person may offer or accept a hazardous material for transportation in commerce within the United States unless that material is properly classed, described, packaged, marked, labelled and in good condition for shipment.

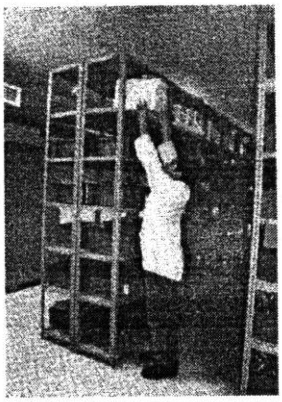
1. Dangerous substances should be handled and stored under the supervision of a competent person who is familiar with the risks and the precautions to be taken.
2. In case of doubt as to the nature of the risk or the precautions to be taken, the necessary instructions should be obtained from the MSDS and the competent authority.
3. When dangerous substances are to be handled or stored, the workers concerned should be given adequate information concerning their nature and the special precautions to be observed in handling them.
4. Special precautions, such as the provision of mats, sling nets, boxes and high sided pallets should be taken to prevent breakage of or damage to containers of dangerous substances.
5. If containers of dangerous substances are broken or damaged to a dangerous extent, work should be stopped and the workers concerned removed to a safe place until the danger has been eliminated.
6. When highly flammable material is being handled, special measures should be taken to ensure that an incipient fire can be controlled immediately.
7. When necessary, non-sparking tools should be provided and used in explosive atmosphere.
8. Where corrosive substances are handled or stored, special precautions should be taken to prevent damage to the containers and to render any spillage harmless.
9. Workers handling harmful substances should thoroughly wash their hands and face with soap and water before taking any food or drink.

2.6.2 Safety in Stacking and Un-stacking :

Neat and orderly stacking or un-stacking minimise hazards and conserve space. Materials piled haphazardly increase accidents and damage to materials. Planned material storage reduces time to bring raw materials into production and to remove finished products from production. The warehouse supervisor should direct the proper stacking and un-stacking.

Adequate ceiling clearance under the sprinklers, side clearance to keep free and clear the electrical panel boxes, switches and other controls and unobstructed access (passageways) to fire hoses and extinguishers must be maintained. All the exits and aisles should be kept clear. Codes on installation of sprinkler systems should be referred for clearance between the storage and the sprinkler heads.

Loading and unloading areas and aisles should be kept clear i.e. no material should be stacked there. Aisle width should allow for the turning radius of any power truck to be used. These areas must be marked or painted with lines.



Unsafe

Safe

Racks, stands, shelves, platforms and bins should be provided to facilitate storage and reduce hazards, e.g. bromine bottles on shelves. Damaged racks should be repaired soon. Workers should not climb racks.

Height indicating line should be painted on wall to show maximum limit of stacking. This helps keep the floor load within limits and sprinkler heads in the clear.

High rack (bay) storage requires unique, specially designed and high lift handling equipment. Upto 30 ft (9 mt) heights manually operated and for more height computer controlled equipment are available. Audible and visual warnings on moving equipment are necessary.

Toxic materials should not be stacked with flammable materials. Volatile material should be kept in a cool shed. Boxed carboys should not be stacked higher than 3 tiers and those of strong oxidising materials, not more than 2 tiers. Incompatibility should also be checked. Proper and sufficient fire fighting arrangement should be provided in and around the storage.

Lifting hoist cage should have safe lift way. It should be so enclosed that material cannot fall on Workers. Landing platforms must have safe guard rails to prevent material to fall from opening.

If two overhead travelling cranes are operated at the same height and on the same rails, limit switches, buffers and alarms must be provided to maintain their safe inter distance and Driver's cabins should face each other.

Paper or cloth rolls, barrels, cylinders and materials which may roll or slip must be stacked safely. Begs and boxes must be kept cross tied and not overhang. Containers must be well marked with the content to avoid mistake in their identification.

Proper ladders, platform and inters tacking containers should be used.

2.6.3 Floor and Lay-out Conditions :

1. **Floors :** Depending upon the load and type of operations, the conditions of the floor such as (a) Cleanliness (b) Absorptive qualities (c) Marking (d) Colour (e) Non-sparking of static disseminating properties and (f) Durability will give great effect on material handling.

   Floor used for stacking should be of sound construction, well maintained, levelled and facilitating drainage. Ground should withstand all weather conditions for the load to be imposed. Stacks should not be built close to railway tracks or in the vicinity of vibrations or possibility of fire.

2. **Walls :** Generally walls are not retaining walls. Therefore load should not be stacked against walls or leaning to wall. A clearance of 18" from wall facilitates inspection of stacks and avoids stacks touching the walls.

3. **Construction of Stacks :** Height base ratio, size, shape, bulk, weight, type, rigidity and fragility of materials and availability of space influence the size of stacks. Normally height should not exceed three times the narrower width.

   Bonding articles in the stack is useful for me stability. Interlocking provides natural bonding. Artificial bonding uses materials like battens, canvas sheets etc. between the tires.

   Stacking should not obstruct fire alarm boxes, sprinklers, controls, fire extinguishers, first-aid boxes, switches, fuses, lights etc. Exits and aisles must be clear. Clearance below sprinkler heads should be more than 2 ft. It should be large enough if the material being stored is inflammable.

   Aisles having one way traffic should be more than 3 feet wider than the widest vehicle when loaded. If the material is to be handled from aisles, turning radius of the power truck should also be considered. Marking line on wall to indicate maximum height of stacking keeps the floor load within limit and the sprinkler heads with clearance,

4. **Lighting :** Inadequate light is a factor behind many slips, falls and injuries. There are various types of light fittings available and these should be selected and used for specific work or areas. The required levels of illumination for different operations are given in Chapter-9. All stores, godowns, yards, workrooms and places of material handling should be properly illuminated.

5. **Ramps :** Ramp gradient should not exceed 1 in 10. It should not be slippery, uneven or broken. It should have sufficient width.

6. **Obstructions :** Pipes, conduits, drains, valves, fire apparatus, etc., are necessary parts of plant structures, yet they often cause hazards. In planning the plant, such parts should be so placed that they may cause minimum interference with persons or materials.

7. **Ladders:** Do not climb on stock-piles. Use ladders. Fixed ladders are preferable. If the height exceeds 2 m provide railing and hand-tools pocket for the ladders. Portable ladder should have non-slip base or its bottom should be held, tied or securely anchored to prevent slipping.

8. **Bridge plates :** Bridge plates should be of adequate strength and they should always be properly anchored.

2.7 Ergonomics of Manual Handling and Storage :

Ergonomics, human factors or human engineering is the study of human characteristics for the appropriate design of the living and work environment. Human characteristics include capabilities, limitations, motivations and desires. Hence, ergonomics is human-centred, trans-disciplinary and application oriented science. Scientific principles, methods and a variety of data are used to develop systems more suitable to people and successful application is measured by improved productivity , efficiency, safety and acceptance of the resultant system design. The user-oriented design philosophy considers human variability as a design parameter and incorporates built-in safe guards to avoid or reduce the impact of unpredictable human error.

Psychology, physiology, biomechanics, anthropology, science and engineering are the main disciplines to be considered in ergonomics.

Work physiology takes into account capacity for physical work. and its energy cost, heart rate at work, matching people and their work, rating the perceived effort, work/rest cycles and fatigue.

Anthropometry ' measures human body dimensions for work and biomechanics explains strength of human body in mechanical terms. It considers muscle strength and its method of working. It is this muscular strength which is mainly used in manual material lifting and handling.

Four keys 'explained by Kroemer (1984) for ergonomics of manual handling are as follows : 3

1. Improved facilities of good layout provides safe and efficient material transfer.
2. Job or task design should consider stress on the worker and should decide whether to assign certain tasks to a person or a machine.
3. Selection, use and improvement of equipment, machines and tools strongly affect material handling requirements. Space requirement, control device, visibility, colour and sign coding etc. should be considered.
4. System must be designed for people as they are king pins of material handling. Their body size, strength and energy capability should be considered.

These four keys provide systematic analysis of material handling problems and many of the risks and strains can be avoided or reduced by intelligent job design, selection and use of equipment and well designed facilities.

See Part 3 of Chapter-24 for more details.

3 MECHANICAL HANDLING

For overall understanding, a classification of material handling process and equipment is given below:

- Material Handling
  - Manual
    - Individual or Team-work. Accessories. Storage and Handling of Specific Materials
  - Mechanical
    - Lifting Equipment
      - Hoists and Lifts
        - For man
        - For material
      - Lifting Machines
        - Cranes, Crabs, Winches, Pulley-blocks, Derricks, Overhead crane, monorail
      - Lifting Tackles
        - Slings, Rings, Hooks, Shackles, Swivels, Couplings, Sockets, Clamps, Trays
    - Transport Equipment
      - Mobile Crane (Crawler, Tyre mounted. Hydra)
      - Industrial Trucks
        - Platform, Pallet, Fork-lift, Reach, Tractor-trailers, Hand lift trucks. Wheel barrows
      - Conveyors
        - Belt, Slat & Apron, Flight, Chain, Screw, Bucket, Pneumatic, Aerial, Portable, Gravity, Chutes, Live roll, Vertical, Pipelines &: pumps
    - Others
      - Mechanical Shovels, Elevators, Escalators

Manual handling is discussed in previous part. Mechanical handling is discussed below.

3.1 Statutory Provisions :

They are as under - .

3.1.1 Factories Act and Rules :

Section 28 and 29 of the Factories Act are regarding hoists and lifts (with platform or cage and fixed way) and lifting machines and tackles.

Difference between 'Lifting machine' and 'Lifting tackle' is explained at the end of sec. 29.

Lifting machine means a crane, crab , winch, teagel, pulley block, gin wheel, transporters or runaway. For figures see Part 3.5.1.

Lifting tackle means any chain sling, rope sling, hook, shackle, swivel, coupling, socket, clamp, tray or similar appliance, whether fixed or movable, used in connection with the raising or lowering of persons or loads by use of lifting machines. For figures see part 3.5.2

Above explanation clarifies that lifting tackles are used with lifting machines and hoists and lifts are not included in lifting machines. Therefore Form No. 9 is prescribed for hoists and lifts and Form No. 10 for any other lifting machine.

The word lifting gear is used to indicate any item which is used fo connect aload to a lifting machine or appliance but which is not in itself capable of providing any movement to lift or lower the load. It is also known as lifting appliance, lifting tool or lifting tackle.

There is no mention of trucks and conveyors. Rule 58 to 60A of the Gujarat Factories Rules prescribe report forms for hoists and lifts (Form No. 9), lifting machines and tackles (Form No. 10) and further details thereof. The abstract of these statutory provisions is incorporated in the following paras.

3.1.2 Bombay Lift Act and Rules :

The Act : The Bombay Lift Act, 1939 has 14 Sections. It applies to the State of Maharashtra.

Section 3 includes definitions of lift, liftcar, lift installation, liftway and liftway enclosure. Here 'Lift' means a hoisting mechanism equipped with a car which moves in a substantially vertical direction, is worked by power and is designed to carry passengers or goods or both.

Sections 4 to 7A require permission to erect a lift, report of completion of erection, licence to use a lift and no operation, addition or alteration to the lift installation without previous permission.

Sections 8 & 8A give rights of Lift Inspector and Owner's duty to provide facilities for inspection.

Section 9 requires accident reporting to the Inspector of Lifts, Commissioner of Police or District

Magistrate, as soon as possible , no interference with the lift installation till inquiry and no re-start without the written permission.

Section II requires six monthly inspection by the inspector authorised. Section 12 gives rule making powers and Section 13 is a penalty provision.

The Rules : The Bombay Lift Rules, 1958 framed u/s 12 of the above Act, provide as under :

Rule 2 gives definitions of 54 terms.

Emergency Stop Switch means a device to cut off power to stop the lift car.

Safety Gear means a mechanical device attached to the car-frame or counter-weight to stop and to hold the lift-car or counter-weight to the guides in the event of free fall or if governor operated at over speed in the descending direction.

Slack Rope Switch means a device incorporating a switch used in a drum-driven lift for automatically cutting off the power in case all or any of the suspension ropes becomes slack.

Permission for installing lift or for making additions or alterations is necessary (R.3 and Form A). Licence for working lift necessary (R.4). It shall not be granted unless requirements laid down in the Schedule are complied with (R.5.). Terms for Licensee (R.6), Report of accidents in Form F within 24 hours (R.8), Unused lifts (R.9) etc. are some other rules.

Schedule u/r 5 gives the most important thirty technical items which include many safety devices. The lift-well for the fire lift, required for more than 24 mt height , shall be segregated by a brick masonry or RCC wall of a fire resistance of more than 2 hours. Minimum landing gate (door) size is 68 cm width and 2 mt height. Interlock devices for gates/doors should be of electro-mechanical type. A special key should be available to open the door in case of emergency. Minimum lift-car height 2 mt. Minimum thrust resistance 75 Ibs without deformation. Man weight criteria 68 Kg. Maximum load to be marked. Overloading prohibited. A push button alarm wired from electric mains other than the lift mains shall be provided. Emergency exit in the car roof necessary. Factor of safety of the combined suspension ropes shall be as under :

For rope speed upto	2 m/s	F.S. – 10
	3.5 m/s	F.S. – 11
	7 m/s	F.S. - 12

Chains are not allowed for suspension ropes. For drum drive two ropes and for traction drive three independent ropes are required for lift-car or counterweight.

More details are prescribed for lift-car safely gear and overspeed governor. The later is meant to retard the descending overspeed.

3.1.3 Gujarat Lifts and Escalator Act, 2000 and Rules 2001

For details, see Part 9 of Chapter 28.

3.2 Indian Standards :

There are many IS on material handling a few of which are : Material handling equipment, non powered, terminology 6839, Hoists and cranes, design, manufacture, erection and testing 807, Hoists and lifts, steel wire suspension ropes for 2365, Hoist chain, electric 6547, electric wire rope 3938, wire slings 12735, for hydraulic gates 6938, 10210, Ropes-coir 1410, 1411, 1412, cotton 2452, 2453, 3143, fibre 3871, 4575, guide 3623, jute 5177, manila 1084, nylon filament 4572, 6590, 3253, test methods 7071, polyethylene 8674, steel wire 1835, 5836, 2266, 3973, aerial ropeway and cable ways 7649, 5229, 5230, Single-chain, mild steel 2760, 8324, legs and wire rope 2762, fibre rope slings 9944, socket 2485, Shackle 4690. 6132, Swivels 4531, C-hook 3813, head nut 10749, Tackle 6549, 5529, Elevator 6930, 7167, Escalators 4591, Conveyors - glossary 4240, safety 7155, apron 7423, 8599, belt 6687, 8597, 8531, chain 7155, 6834, screw 5563, Electric passenger and goods lifts 1860, 3534, 6620, inspection of lift wire ropes 8216, Hand operated chain pulley blocks 3832, Portable mine hoist 11922, Round steel short link chain (electric butt welded) grade 30, 2429, grade 40, 3109, Gas cylinders safety devices 5903, colour code 5, handling 3870, Safety for handling cryogenic liquids (liquefied gases viz. 0,, N,, H,, Helium, argon, neon and krypton) 5931. Powered industrial trucks 6305, 7552, 7553, 7862, cable lift 4289, chain lifting safe use 8324, Gantry travelling crane 3177, for lifting air cargo 12462, winch 9507, wheel barrows 2431, 4814.

Safety nets 11057, Metal hooks, clips and eyes 4066, Crane, safe working loads 6511. Stability testing of forklift trucks 4357, Platform trucks 7361, 10311, Side loader trucks 9075, Powered tow trucks

10312, Safety Code for handling and storage of building materials 7969, Safety Code for scaffolds and ladders 3696.

Packaging code 10106, Pictorial markings for handling and labelling of goods 1260, Requirements for packing pesticides 8190.

IS :1860 Code of Practice for Installation, Operation and Maintenance of Electric Passenger and Goods Lifts is worth mentioning.

It includes 58 definitions (terminology) and essential requirements -like conformity with statutory provisions and IS, lift wells, lift pits, bottom and top clearance, well enclosures, lift cars, locking devices, suspension ropes, counter-weights, buffers, emergency safety device, safety gear tests, slack rope switch, automatic power cutting device, electric wiring and apparatus.

It gives design consideration of number of lifts and capacity, passenger lifts, goods lifts, hospital bed lifts, positioning of lifts, positioning of machine room, structural consideration, fire protection, quiet operation, supply cables and switches.

It also deals with testing, running, maintenance and general information to be given with inquiry and order.

These Indian Standards are very much useful for design, construction, use, operation and maintenance of lifting equipments.

3.3 General Requirements of Mechanical Handling:

Mechanical handling is defined as the movement of goods by mechanical force for the purpose of feeding, loading or unloading to or from a machine, plant or storage place, to or from a means of transport such as vehicles, ships or air transport.

The equipment employed may be powered by electromagnetic, hydraulic or pneumatic energy,

Main hazards of mechanical handling are contact with moving dangerous parts (pulley-belts, gears, in-running nips, couplings etc.), falling from the height or on the floor, striking against or struck by falling bodies.

3.3.1 Types & Uses :

Types of mechanical material handling equipment are classified in the beginning of this Part 3.

Factors affecting selection of means of handling and lifting are : Weight, shape, size, physical and chemical character, rate of handling, purpose and distance of moving, obstacles if any, structural condition of the floor, pathway and direction of movement.

Uses of the main mechanical handling equipment are given below :

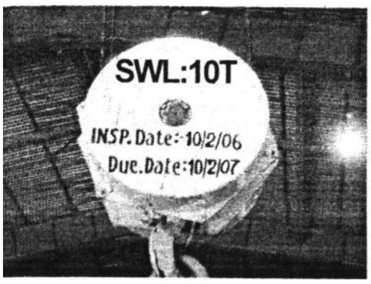
Equipment	Useful for
Electric Overhead Travelling crane (EOT)	Lifting, shifting and placing, anywhere in the traveling area.
Jib Crane (Mobile) Gantry crane	Lifting and shifting at desired places.
Power trucks	Three or four wheeler truck to pick, hold and carry (transport) material. Useful in making piles,

	stacking and unstacking.
Power trucks	Three or four wheeler truck to pick, hold and carry (transport) material. Useful in making piles, stacking and unstacking.
Conveyors	Transporting/Carrying material between two fixed points. Useful as a feeding device where manual feeding is unsafe. Workers should not ride on conveyors.
Lifting tackles	They are rings and slings (chain or rope, metal or fibre), hooks, shackles and swivels. They are used to connect load or container to nay lifting device.
For Lift Truck	It is a power truck having projecting fork to pick, hold, carry and unload (replace) the material or container. May be power driven or battery operated. Conveniently used on smooth floor.
Pay loaders, Power shovels, Winch crab, Pullers and Hydraulic/ Pneumatic jacks	Used to dig, lift and transport heavy material. Well trained operators, supervision and good maintenance are necessary.
Lifts and Elevators	Moves vertical, horizontal or in any unilateral direction (cable path) between two fixed points, lift vertically and carry material or persons. A cage or cabin must travel in a fixed path and well enclosed. Interlocked doors/gates necessary.
Hoists.	Hoists are of three types : Electric, pneumatic and hand operated chain hoists. Chain hoists are of three types - spur geared, differential and screw geared i.e. worm drive. The spur-geared type is most efficient Push-button cable must be supported by a chain to protect against strain.
Mono-rails	Should be well supported on both ends like a hanging bridge. The chain pulley block or hoist mounted on it should move freely. Stops must be provided at both the ends. Useful to lift load and carry horizontally between two fixed points.

3.3.2 Safe Working Load :

Safe Working Load (SWL) is the limiting safety factor to lift and carry any load safely. It must be clearly marked on any lifting device (hoists, lifts, lifting machines and tackles).

Section 28(l)(c) of the Factories Act, prescribes as under :



"The maximum safe working load shall be plainly marked on every hoist or lift, and no load greater than such load shall be carried thereon."

Section 29(1)(b) of the same Act, prescribes as under :

"No lifting machine and no chain, rope or lifting tackle shall, except for the purpose of test, be loaded beyond the safe working load which shall be plainly marked and duly entered in the prescribed register, and where this is not practicable, a table showing the safe working loads of every kind and size of lifting machine or chain, rope or lifting tackle in use shall be displayed in prominent positions on the premises."

Rule 60 of the Gujarat Factories Rules 1963 requires that:

1. The safe working load has to be specified by a competent person after thorough testing and examination.
2. Where the safe working load may be varied by the raising or lowering of the jib, a table indicating the SWL at corresponding indication of the jib or corresponding radii of .the load shall be attached with the jib-crane.
3. A table showing the SWL of every kind and size of chain, rope or lifting tackle in use, and in case of a multiple sling, the SWL at different angles of the legs, shall be posted in the store room.

Marking System of SWL :

Lifting equipment should have a tally plate indicating the SWL. The tally plate also indicates the identification number which can be mentioned in die test certificate held by the user. It should also indicate the date of last inspection.

Safe Working Load of different types of slings are given in the table below :

Safe working load in straight pull 	Choke 	Basket 0^{o} 	Basket 0-90^{o} 	Basket 120^{o} 	ELTECH SLINGS	COLOUR
Kg	Kg	Kg	Kg	Kg	Average Dia in mm	
1000	800	2000	1400	1000	18	VIOLET
2000	1600	4000	2800	2000	20	GREEN
3000	2400	6000	4200	3000	22	YELLOW
4000	3200	8000	5600	4000	25	GRAY
5000	4000	10000	7000	5000	27	RED
6000	4800	12000	8400	6000	32	BROWN
8000	6400	16000	11200	8000	38	BLUE
10000	8000	20000	14000	10000	46	L. GREEN
12000	9600	24000	16800	12000	58	GRAY
15000	12000	30000	21000	15000	70	ORANGE
20000	16000	40000	28000	20000	78	ORANGE
36000	28000	72000	50400	36000	114	ORANGE

Place of marking of SWL of different equipment is shown in the table below :

Type of Equipment	Place of Marking of SWL *
Lifting eye bolt	Side of the eye. Size and type of thread also be marked.
Shackles	On one leg SWL and on other leg identification mark and symbol are marked.
Chain Sling	On terminal fitting (ring) or on a separate idel link.
Multiple legged slings	SWL at 90^{o} angle is marked on upper terminal ring.

Wire ropes	A metal sleeve or tag with marking is attached.
Chains	Marking for quality of material on every 20^{th} link or 3 feet apart whichever is less. SWL on chain sling.
Hooks	SWL on one side of non vital part and on reverse side the identification mark.
* Where marking on the body part is not possible, it should be shown by tagging.	

Calculation of SWL:

$$SWL = \frac{\text{Minimum breaking load quoted by the manufacturer}}{\text{Factor of Safety}}$$

For wire ropes, FS is 6 for general purpose and 7 for heavy industry. A thumb rule formula is

SWL = $(\text{Wire rope dia})^2 \times 8$ kgs
viz. for 12 mm dia wire rope,
SWL = 12^2 x8= 1152 kgs

For slings, SWL depends on the length of the sling leg (L) and headroom between the hook and the load (H). Then for bridge hitch

SWL = SWL of single vertical hitch x H/L x 2
For double basket hitch,
SWL = SWL of single vertical hitch x H/L x 4

Tables showing the SWL of all slings at different angles of the legs shall be posted in prominent positions at work place.

For hoists, lifts, cranes etc., SWL is recommended by the manufacturer.

SWL of any mobile crane depends on operator's skill, condition of the ground, boom length, radius of rotation while lifting the load, -inclination of boom to the vertical and out rigger blocked or free.

SWL is generally tabulated in the load chart of the crane. Sometimes, it is de-rated (decreased) due to defects in welding, bend in angle, bracing etc. and condition of clutch, brake etc. Modern cranes give digital display of SWL and alarm for exceeding load.

Factor of safety of fibre ropes varies from 6 to 12 depending on conditions of use. Fibre rope less than 12 mm dia should not be used for a sling or a part of a lifting appliance. Their factor of safety (FS) varies with diameter. Factor of Safety for hook, wire rope sling, chain, fiber rope and belt are given in the table below:

No.	Item	Factor of Safety
1	Mild Steel Hook	5
2	High Tensile Steel Hook	5
3	Wire Rope Sling	6
4	Endless Wire Rope Sling	8
5	C Hook	5
6	Shank Hook (General Purpose)	5
7	C Hook with Eye (0.25 T)	4
8	Point Hook with Shank (63-160 T)	5

9	Hook (General Purpose 1-25 T)	4
10	Hook (General Purpose 25-100 T)	As per IS : 7847
11	Chain Gr. : 30	4
12	Chain Gr. : 40	4
13	Chain Gr. : 63	4
14	Chain Gr. : 80	4
15	Chain Sling	4
16	Eye Hook for Chain Sling	4
17	Synthetic Fiber Rope	
	Diameter	
	12 mm.	12
	14-17 mm.	10
	18-23 mm.	8
	24-29 mm.	7
	40 and above	6
18	Polyester Belt	7 (For belt)
		4 (For end fitting)

3.3.3 Proof Test:

Proof testing is the application of a load greater than the SWL to detect defective workmanship, faulty welds or other inherent weaknesses. It is not a means to assess the SWL which should only be done by calculations and checked where necessary by suitable tests on samples.

Proof test is required as a part of 'thorough examination' u/r 60(1) of GFR and no lifting machine or tackle should be used for the first time without this proof test.

In general the proof load applied to chains, rings, hooks, shackles and similar gear is twice the SWL. It should be just under the yield stress for the material.

The standard proof load for mild steel or wrought iron short link chain is as under :

Grade	Test load in Tons
Upto 30	$12\ d^2$
Upto 40	$16\ d^2$
Upto 60	$24\ d^2$
Upto 80	$32\ d^2$

Where 'd" is the diameter of the material from which the chain is made.

All items used in lifting machinery should be subjected to proof test loads as under :

Item	Proof Test Load
Chains, ring, hook, shackles, swivels, slings, individual components of hoists, wire rope, chain, pulleys, hooks, eye bolts, pins, axles, bearings, turn buckles & ringing screws.	2 SWL
Single sheave pulley blocks	4 SWL
Multiple sheave pulley blocks	
Up to 20 T	2 SWL
Up to 40 T	SWL + 20 T

Over 40 T	1.5 SWL
Electric Hoists, Cranes (Mobile & EOT)	
UP to 20 T	1.25 SWL
20 to 50 T	SWL + 5 T
Over 50 T	1.10 SWL
Endless Slings	4 SWL of single part
Derricks	1.25 SWL static & 1 SWL for all full movement.

After above proof examined thoroughly by signs of cracks, fatigue, stretch etc.

3.4 Lifts and Hoists :

The Factories Act requires as under

Every hoist and lift shall be of good mechanical construction, sound material and adequate strength, properly maintained and examined by a competent person at least once in every six months. Its report should be in Form No. 9, GFR.

Good construction means as per standards (e.g. IS). Sound material means as per required quality of the material. Adequate strength means proper design, factor of safety and good workmanship. Properly maintained means following safe and standard procedures, work permits, manufacturer's and other guidelines.

Every hoist or lift shall have the safe working load plainly marked on it and no load greater than such load should be carried on it. The cage of every hoist or lift used for carrying persons should be fitted with a gate on each side from which access is afforded to a landing and such gates should be fitted with interlocking or other efficient devices to ensure that they cannot be opened except when the cage is at the landing and the cage cannot be moved unless all the gates are closed.

Whenever the cage is supported by rope or chain, there shall be at least two ropes or chains separately connected with the cage and balance weight and each rope or chain with its attachments should be capable of carrying the whole weight of the cage together with the maximum load. Efficient devices should be provided and maintained capable of supporting the cage together with the maximum load in the event of breakage of the ropes, chains or attachments. There should also be an efficient automatic device to prevent the cage from overrunning.

Gujarat Lift Act and Rules provide more details. See Part 3.1.3.

See Rule 65 and 78 of the Building Workers Central Rules, 1998. (Part 7.2, Chapter-28).

Horsepower to lift a load is given by the following formula:

$$HP = \frac{L \times S}{450}$$

Where L = load in Ibs and S = speed of lift in ft/sec.

For example, if one ton load is to be lifted at 5 ft/sec, HP of an electric motor should be :

$$HP = \frac{2240 \text{ Ibs} \times 5 \text{ fl/sec}}{450} = 24.88 = 25$$

Similarly load on the line can also be determined. For example, when a 30 HP motor moves a drag bucket 60 ft in 10 seconds, the load on the line is

$$L = \frac{HP \times 550}{S} = \frac{30 \times 550 \times 10}{60} = 2750 \text{ lbs}$$

Here I HP = 550 foot-pounds per second are considered and not the figure of 450 which allows for friction losses.

Since an electric motor can deliver 50% overload for a short time, the maximum load on the above motor (and the lifting line) could reach 2750 x 1.5 = 4125 Ibs, if the drag bucket struck an obstruction.

3.4.1 Safety in Design, Construction and Operation :

General requirements are as under :

1. Hoist limit switch to cut of power and apply brakes when hook/cage rises to a predetermined level to prevent over-winding.
2. Limit switches to prevent over travelling and over transferring.
   These limit switches should automatically reset within a reasonable distance travelled in' the opposite direction.

3. Emergency push button for prompt use.
4. Isolation switch to cut off all power except lighting. Proper earthing.
5. Off position interlocking to prevent the circuit breaker from being closed unless all controllers are in off position.
6. Screen on bare conductors.
7. Pilot lamp (red lens) to indicate on or off condition.
8. Hand lamp of 25 volt DC or AC.
9. Earthing as per Electricity Rules.
10. Means of anchoring when the hoist/crane is left unattended or under storm conditions.
11. Others : Sheaves guard to retain ropes in grooves, safe means of access, ladders and guards on moving/rotating parts. Examination for wear, malfunction, damage and proper operation of hooks, ropes, brakes, clutches and limit switches.
12. Safety points for operation : No loading over SWL. Marking of SWL and load indicators for varying SWL. Pick up load only when it is directly under the hook, otherwise stresses will develop. Full vision in driver's cabin. Fire extinguishers, warning device, safe operating precautions for raising and lowering loads, moving loads over workers working underneath and duties of drivers while leaving the cabin, should be prescribed and followed. People should not be lifted or transported by hoist or crane.

Safety Aspects of Lifts or Elevators:

Following are the specific safety aspects for safe design and operation of lifts or elevators:

1. **Lift Wells :** No projection inside, sufficient space for repairs and maintenance, fire proof to the maximum extent.

2. **Lift Well Enclosures :** Enclosed construction, if wire mesh, opening should not be more than 32 mm. Clearance between moving car and the platform sill or wall shall not be more than 25 mm to avoid trapping.

3. **Lift Pit :** It should be waterproof to disallow water from outside.

4. **Top & Bottom Clearance :** Minimum I mt in the top and I mt in the bottom.

5. **Landing Gate & Doors :** Landing door should cover the full size of the car gate opening and if it is collapsible, grill opening should not be of more than 6 cms wide and if it is solid, it should have a vision panel of not more than 25 mm width. Solid door is safer.

6. **Interlocked Gates & Doors :** Lift car shall not, move until all landing doors are closed and they will not open till the car is moving, except by a special key. Automatic door-closures are useful.

7. **Lift Cars :** Enclosed type, smooth and non-slippery floor, alarm and push button, light, ventilation, plug-socket on car top to take power supply for maintenance work, factor of safety more than 5, marking of 'persons' capacity' (base 68 kg per person)

8. **Counter Weight :** Should be in a steel frame, secured by two tie rods to prevent fall and travel in rigid steel guide.

9. **Buffers :** Spring or hydraulic type, of adequate strength, on the pit floor to absorb shocks if the car falls.

10. **Suspension Ropes :** 3 independent ropes for traction drive and 2 ropes with drum drive each rope separately and independently fixed to car and counter-weight, ropes free from joints and factor of safety more than 12 based on static contact load + weight of car and accessories.

11. **Emergency Safety Device :** Safety gear Instantaneous type. Gradual Wedge clamp or Flexible guide clamp - to retard the speed if it exceeds I m/s and operating on both the guides.

12. **Over Speed Governor :** It prevents the car from falling or overspeeding downwards. If speed exceeds the normal design speed, the governor applies brakes on the car driving mechanism and also releases safety clamps against the guide rails to bring the car to a smooth sliding stop.

13. **Slack Rope Switch :** If the car is obstructed while descending and the rope becomes slack, this switch will stop the machine.

14. **Machine Room :** Height should be more than 2 m, space around m/c more than 60 cm, hand lamp provided and room locked with a key, with the authorised person.

15. **Machine Supports :** Supporting beams shall be of steel or RCC. The factor of safety shall be 5 for steel and 7 for RCC.

16. **Final Limit Switches :** Upper and lower ultimate switches to stop the car automatically within the top and bottom clearances independently of the normal operating device and the terminal limit switches.

For statutory provisions see Part 9 of Chapter 28.

3.4.2 Testing, Inspection and Maintenance:

Testing includes insulation tests for electric wiring. Test voltage should be DC (more than twice the rated voltage) and insulation resistance of each wiring circuit should be more than 2 m ohms.

Tests for satisfactory operation of each controller, switch, contactor, relay, interlocks, sequence of operation, protective devices. Tolerance on specified speeds at full load shall be within 10%.

Overload test by 125% of the working load. Proof (test) load may vary from 1.5 to 4 times of the SWL as mentioned in Part 3.3.3. Sample of wire ropes should be tested.

Periodic inspections to detect unsafe conditions, warn or damaged parts, wear and other defects in wire and fibre ropes, lifting gear, tyres etc. are necessary.

Gear wheels and pinions should be maintained in good condition, properly keyed and in their correct gear mesh. Gear wheels and pinions with broken teeth or cracked areas, rims or bosses should be discarded and replaced. The faces of all ratchets, jaw clutches, gear locks and collars should be kept in their correct relationship to ensure safety in use.

Repairs shall be carried out by 'permit to work' system. All power shall be disconnected while doing such work.

Notices like 'under repair' 'out of order' 'don't' . start' etc. shall be displayed.

3.4.3 Signalling :

Importance of proper signalling for co-operation between the hoist/crane operator and the slingers/ signallers or the motion indicators should be recognised, a code of practice should be developed and followed.

Signaller (hook-on person) should be thoroughly acquainted with the standard hand signals, the operation of the lifting equipment, the correct methods of securing, handling, stacking and piling loads and should be completely responsible for arranging slings or other hook-on devices and giving the signals that direct the equipment operator during the moving of the load.

The crane operator shall respond to signals only from the appointed (trained) signaller but shall obey a stop signal at any time from any body.

See fig. 15.1 for standard hand signals.

Refer rule 60 (8) the Gujarat Factories Rules.

3.5 Lifting Machines and Tackles :

Statutory provisions of Gujarat Factories Rules, Dock Workers Safety Rules and Building and Other Construction Workers Rules should be referred for details.

According to the Factories Rules, no lifting machines, chains, ropes and lifting tackles should be taken into use unless it has been tested and all parts have been thoroughly examined by a competent person and a certificate of such examination specifying the safe working load is obtained.

Also no lifting machine, chain, rope or lifting tackle should, except for the purpose of testing, be loaded beyond the safe working load. The safe working ' load shall be plainly marked on each such gear together with an identification mark and corresponding entries made in a register. Whenever these cannot be marked, a table showing the safe working loads of every kind and size of lifting machine, chain rope or lifting tackle in use should be displayed in prominent positions.

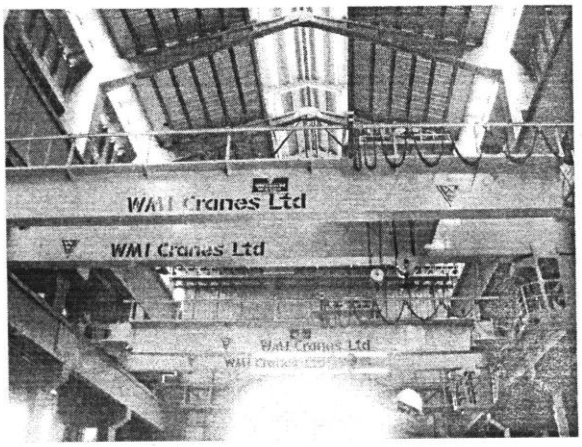
3.5.1 Types and Safety aspects of Lifting Machines :

Lifting machine means crane, puUy block, mono rail, crab, winch, derric etc.

Different types of cranes are available. Their selection depends upon type of use. Jib crane, pillar crane, climbing crane, overhead crane (manual or power driven), gantry crane, cantilever gantry crane, semi-gantry crane, hammerhead crane, wall crane etc.

Detailed safety rules for inspection, operation, signalling and maintenance should be available in writing, the operators should be trained for that and they should be strictly followed. Chapter-VII (R.55 to 81) of the Building & Construction Workers Rules is most relevant. See also Part 7.2 of Chapter-28.

Overhead Travelling Cranes : Electrically operated (power driven) overhead travelling cranes are known as EOT or OET cranes. Others are non-powered i.e. manually operated overhead travelling cranes. In the use of overhead cranes, great care should be taken for the safe and adequate means of access. It is necessary that all ladders and steps should be



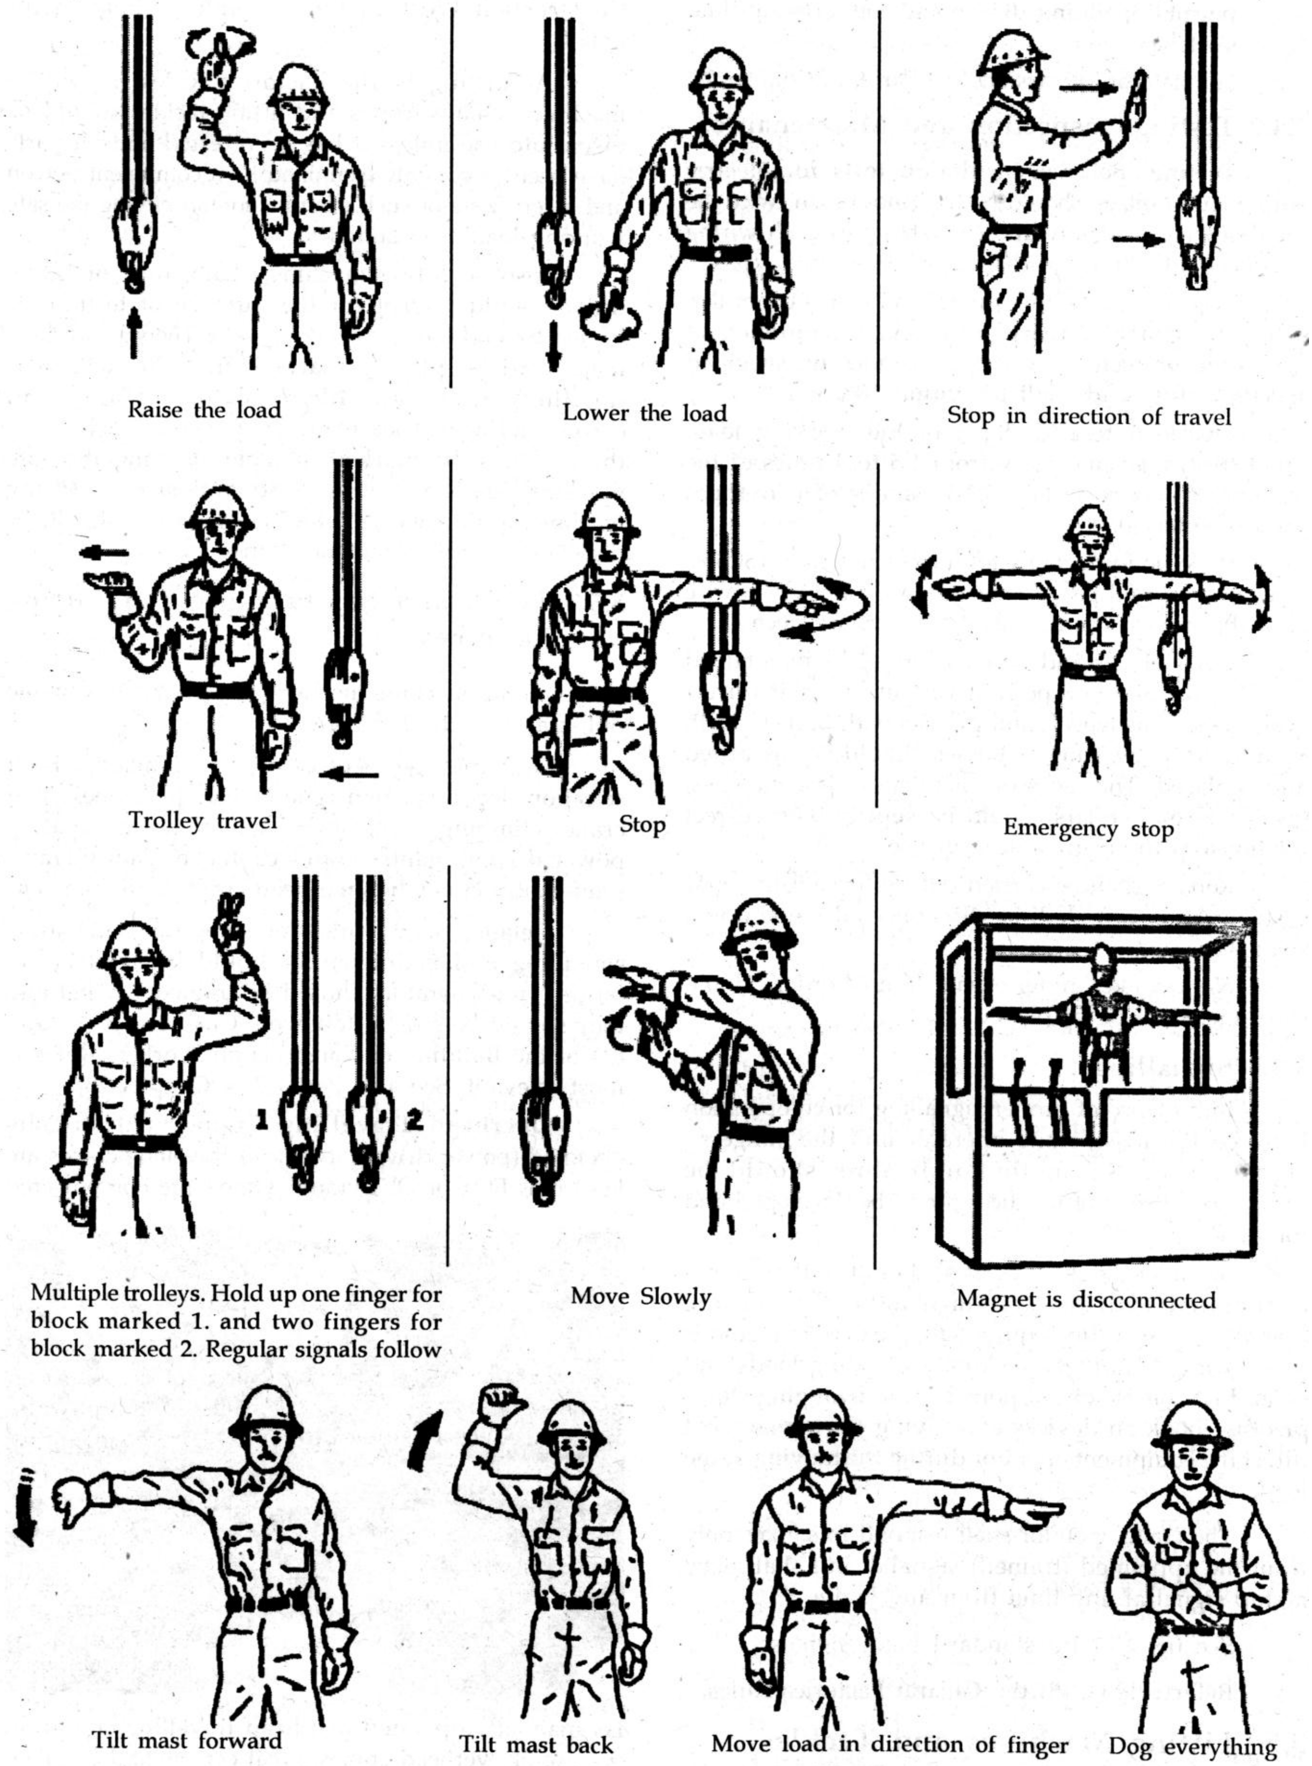


Fig. 15.1 Standard hand signals

provided with secure handholds and footholds. Stairways are preferable to ladders. Proper landing or stages should be provided at the point of transfer from ladder to the driver's cabin.

While any person is employed or is working on or near the wheel track of a travelling crane in any place where he would be liable to be struck by the crane, effective measures shall be taken to ensure that the crane docs not approach 6 m of the place. Effective means should be arranged to prevent a crane from travelling into the dangerous zone.

Passage way for crane : The passage (walk way) (= 50 cm width, toe board 10 cm) shall be provided at a lower level than the crane track and safe access ladders (width > 40 cm, double hand rails of 90 cm high) shall also be provided at suitable intervals to afford access to these passage ways and from passage ways to the rails track [Rule 60A GFR]. Vertical head clearance between the walkway and the overhead structure should be more than 2 m. Walkway surface should be non-slip type and without floor openings.

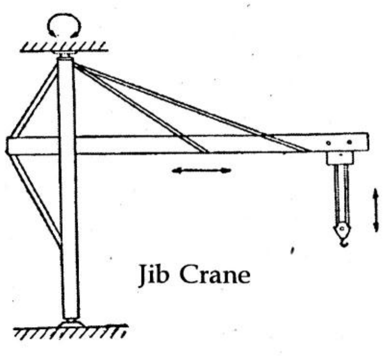
Rubber mat at the control panel in the cab is necessary to protect against electric shock. The cabdriver should have full view of the area of work. Rail alignment should be checked every year. Rail stops or bumpers should be so located that when contacted, the crane bridge remains right angle with the runway.

When not in use, a -crane should be' parked with hook raised at a safer height, all controls in off position and the main switch open.

Inspection and testing of heavy duty EOT crane include deflection test, over load test, operation test, insulation test, warning light test, earthing and bonding check, hoist and track limit switches check, proximity warning device check, braking and locking check, control gear check, guarding and weather protection, means of access, buffers and wire ropes of sufficient capacities. -All control mechanism, safety devices, leakage in air or hydraulic system, hooks and ropes, electrical apparatus, travel and steering devices should be properly checked. Preventive maintenance is most desirable. Moving parts should be regularly lubricated. A crane should not be left unattended. Crane operators must be fully trained for safe operations.

Deflection test must be carried out with the SWL M rest and with the crab in a central position. The deflection should not exceed 1/900 of the span.

Jib Cranes : A jib crane means a stationary or mobile crane in which suspension rope is supported by a projecting, horizontal or inclined member known as a jib. Jib crane can lift, lower and rotate the load within the circular arc covered by a rotating arm or jib.



Jib Crane

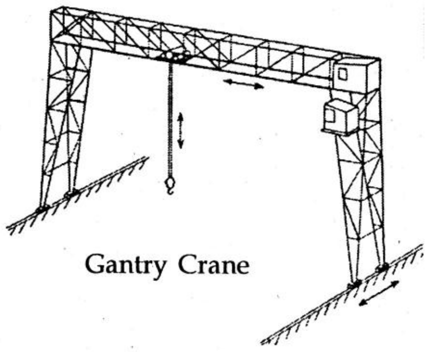
It is important that capacity of the jib crane clearly showing the maximum safe working load for the various inclination of the jib or various positions of the trolley on horizontal jib should be marked on the sides of the jib or on the mast or on the pillars.

A number o accidents have occurred due to overloading of jib cranes. It should be fitted with automatic indicators which will give efficient sound signals whenever the load moved is in excess of the safe working load.

Structure (floor, wall or column) should be checked for its strength before mounting a jib crane. The jib should be guyed or braced to withstand heavy load.

A stop plate (bumper) at the end of the jib is necessary to prevent the load trolley from running oft the beam. It should be frequently checked.

Bridge and Gantry Cranes : These are similar to travelling cranes except that they run on rails at ground level instead of on elevated runway girders. Gantry cranes have short spans, while bridge cranes may have spans upto 100 m or more. Bridge cranes are usually used for handling coal or ore. Sweep guards on nip between rail and wheels, rail clamps and brakes to prevent movement due to high wind, safe height of electric contact rails, operator's cabin to be fireproof and weatherproof, I m side clearance with the truck wheels of gantry cranes, skew switches to prevent excessive distortion of the bridge etc., are some .of the safety measures.



Gantry Crane

A sounding device (gong) should always warn when the crane is moving. The bumpers should be of cast steel plates or spring type. Floor or foot-walk should have drainage, a handrail and toe board up to entrance landing. A rope ladder in the cab for emergency escape and locking ratchets on wheel locks, rail clamps and brakes to secure against high wind etc. are necessary.

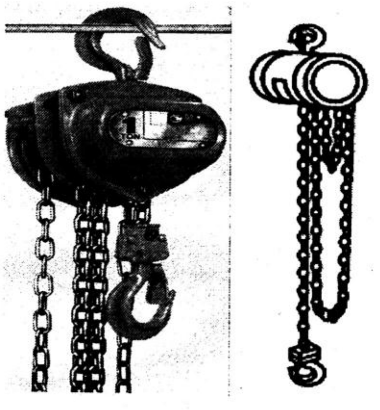
General requirement for all crane equipment are : good construction, sound material, adequate strength and free from patent defect. It should be regularly inspected and properly used. Statutory provisions must be followed.

Design safety measures should include over-travel limit switches, protection of bare conductors, controls to prevent inadvertent operation, load indicators (audio-visual automatic excess load indicator), safety catches, emergency escape, operating position and marking of SWL.

Safe operating techniques must be taught to the operator.

Lifting accessories - chain, wire rope or fibre rope slings, eyebolts, shackles and special lifting equipment must be of good construction, sufficient strength, properly designed and heat-treated as per requirement.

See Rule 80 of the Building Workers Central Rules 1998 for 'Tower Cranes'.



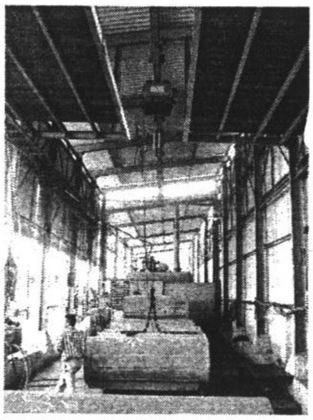
Pulley-blocks or Chain Hoists : These are spur geared, screw geared and differential chain hoists. They may be portable, portable but permanently hooked onto a monorail trolley or built into the trolley as an integral part. They are suitable for many operations on which a block and tackle fitted with manila rope is used and are stronger and more dependable than rope tackle.

The spur geared type is the most efficient. Screw-geared and differential hoists are self-locking to automatically hold a load in position. Load carrying parts should be made of steel. The load safety factor of chains should be more than 5. It should be more than 10 for manila rope.

While using pulley block in confined spaces, the whole block or the rope or wire nip should be guarded.

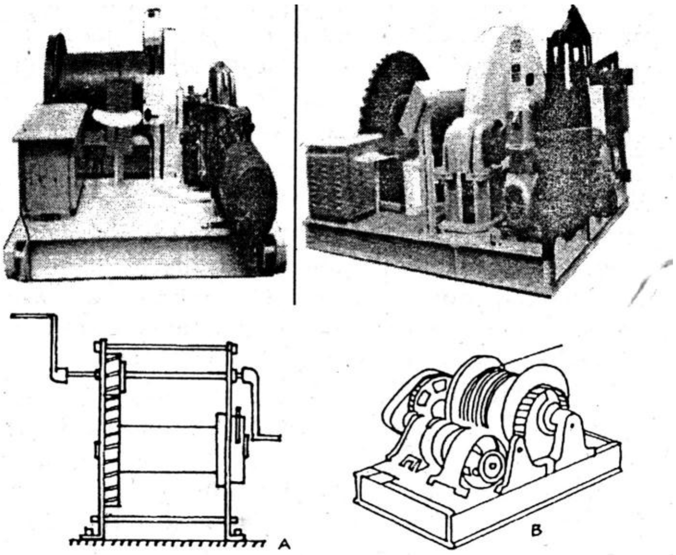
The safe working load should be plainly marked on the block and it should be tested every year. All parts subject to wear should be frequently examined.

See Rule 60 and Form (test report) 10 under the Gujarat Factories Rules and Schedule I and Forms VI to X under the Building and other Construction Workers (Central) Rules 1998.



Monorails : This system consists of one or more independent trolleys supported from or within an overhead track from which hoists are suspended. Monorail hoists are used to raise, lower and transport materials. They are of three types - hand operated, semi hand operated and fully power operated. Rail stops at the ends of monorail tracks are desirable. Tracks and their supports must be checked for strength and smooth running.

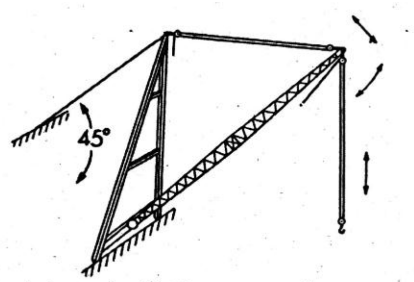
Crabs and Winches : They may be hand operated or electrically driven. Portable crabs and



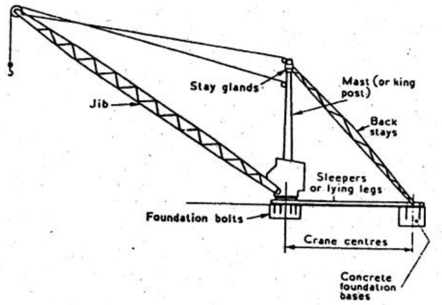
winches must be securely anchored against the pull of the hoisting rope or chain. A dog to lock the gears and a brake or safety lowering devices, crank-pin, lever on pawl and gear guards are necessary. Barricade guards are necessary to protect the operator against breaking wire and recoil of broken ropes.

See Rule 59 & 81 of the Building Workers Central Rules, 1998.

Derricks: Main types are the stiff-leg, A-frame, guy, ginpole and the breast derrick. With all derricks,



A frame derrick. Brace set at 45° to the



Derrick Crane mounted on Concrete Blocks

every part should be firmly anchored. Striking from mast, boom, sill, pulley block and swivel hook should be prevented. The hoist engine should be firmly tightened with the base to prevent its pull out. Derrick foot must be firmly supported. For safe rigging of derrick and its gear, rigging plans should be available.

See Part 4.1 of Chapter-22 for further details.

Hazards and Precautions of Remote operated Lifting Machines:

They are as under :

Hazards:

1. As directions (EWNS) are mentioned on the remote, operator is likely to be confused.
2. Chances of accidents in case of wrong movement of direction are possible.
3. As the operator is operating from the ground, his attention is deviated by the co-worker resulting in accident.
4. Person not trained in crane operation also tends to operate the crane, as remote (pendant) is easily accessible.
5. In case the "Push Button" or lever gear is pressed by mistake, crane motion may start automatically.
6. Operator may lock the motion by mechanical means in order to avoid holding by operating the push button/lever.
7. Motion of the crane is activated by radio frequency. Interference by other radio frequency may move the crane automatically and cause dangerous situation. 8 In case of emergency, main switch is not easily accessible. Main switch of DSL may be far away.

Advantages:

1. Operator is not required to climb on the lifting machine.
2. Operator can operate the crane close to the load; this gives more accuracy and precision in handling.
3. Communication between operator and attendant (slinger) is better. Hand signaling may not be required, verbal communication is possible.
4. Operation of crane is easier.
5. For smaller lifting, the work of slinger (attendant) may be carried out by operator himself.

6. Attendant (slinger) or any other person can easily be trained for crane operation.
7. No chance of electrical shock as it is completely isolated from high voltage.

Disadvantages:

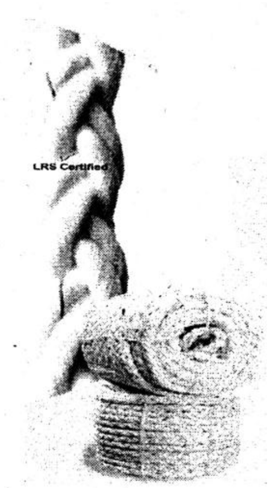
1 As the remote works on radio frequency operator may operate the crane from any place. He may not be moving close with the load.
2 Crane remains unattended, as operator is not close to the crane. Any abnormality like noise, vibration, loose part, lubrication, is not noticed regularly.
3 Maintenance person or operator is required to check the crane separately, regular (daily) inspection by operator may not be possible.
4 In case of operating from ground, the operator doesn't get the overall view of complete scene, e.g. obstruction in the part of a moving crane.
5 Main switch in the control cabin is not accessible.
6 Licence is required for radio frequency used for remote control.

3.5.2. Types and Safety aspects of Lifting Tackles :

Lifting tackles, gear or appliance means fibre rope slings, wire rope slings, chain slings, hooks, rings, sheaves (grooved pulleys), swivel, shackles and similar gears.

Ropes : Generally manila and sisal ropes are used in hoisting, lowering and handling operations. There are various grades of ropes and therefore while purchasing, their guaranteed breaking strength should be obtained from the manufacturer in order to assess the safe working loads of the ropes.

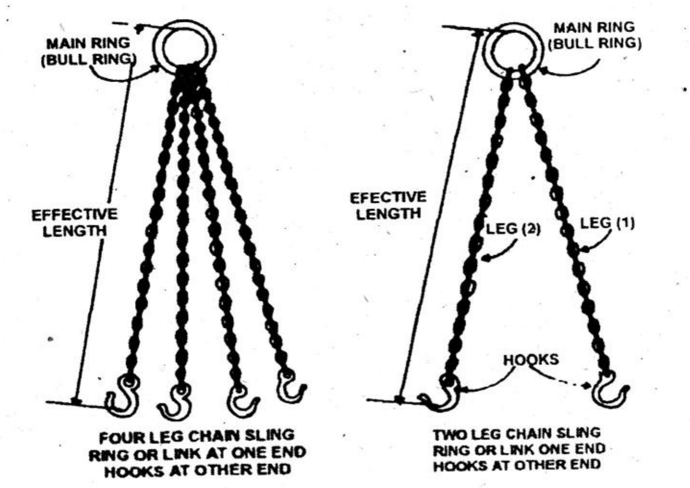
Fibre ropes are very susceptible to mechanical damage and they should therefore be frequently inspected for their strength. Particular care is necessary when it is suspected that the rope may have been contaminated by chemical action.



Fibre rope of less than 12 mm dia should not be used for a sling or a lifting device. For ropes, safe working load can be calculated by dividing the minimum breaking load quoted by the manufacturer by factor of safety depending on the use. For SWL and factor of safety see Part 3.3.2.

Periodical inspection of the whole length of rope is necessary to detect broken wires, amount of wear, corrosion, rust etc. Broken wires in a rope must always be regarded as a warning sign. Wire ropes must not be knotted. They should be joined solacing.

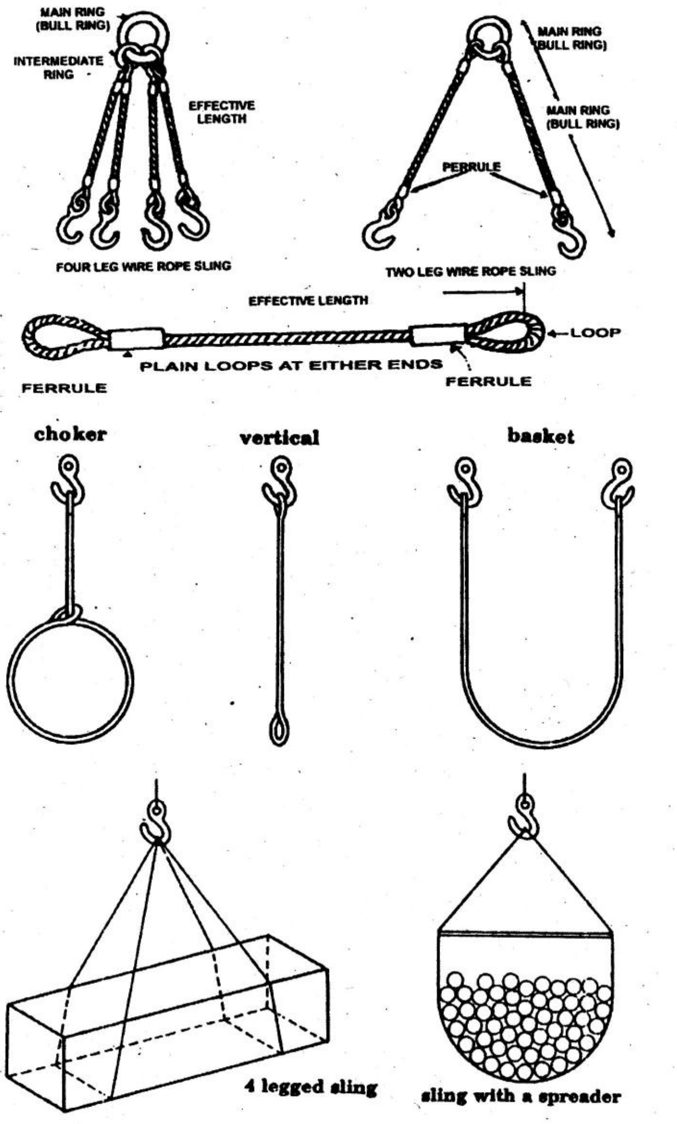
For the same working load, the chain sling is 5 to 8 times as heavy as wire rope but it has a longer life, stands up better-rough use and is almost 100% flexible. The chain is obtainable in many grades viz. wrought iron, mild steel, high tensile steel and alloy steel. Wrought chains require to be periodically heat treated to remove brittleness.



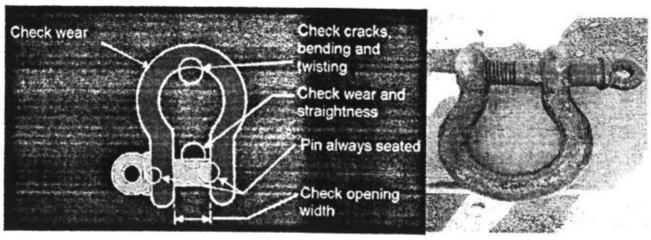
the number of legs. For example, when a 2 ton load is lifted by directly booking to the chain or cable, the load on the line is 2 tons. But if it is hooked to a two-legged sling, the leg of each sling carries I ton (while the line connected to the sling holds 2 tons). If ifs a four-legged sling, each leg carries 0.5 ton.

The stress in any leg increases as the angle of tile leg with t1ie horizontal decreases. In the two-legged sling, each leg carries a stress equal to the total load when the angle is 30°, and a stress of nearly six times the load when the angle is 5°. Therefore it is important to keep the angle as large as possible and the stresses be computed carefully to maintain a reasonable safety factor.

While using a sling, the ratio of the load lifted by any leg of the sling is inversely proportional to **Hook** is either of a circular section oi trapezoidal. The former is meant for light loads up to 5 tons. See part 2.5 for figures.



Shackles according to difference in shapes are known respectively as D and Bow shackles. The pins are usually of circular section. The methods of securing



'D' shackle Bow shackle

shackle pins in position vary according to the nature of the use of the shackles. When there is a risk of the pin coming out, pins are secured by means of a nut and a cotter pin. A cotter pin affords more rigidity than a plain pin.

All slings, rings, hooks, shackles, swivels, couplings, sockets etc., should be as per Indian Standards. Permissible working load of one leg should be calculated from the ready table of sling diameter and varying angles between two legs.

Plate lifting clamps are shown in fig. 15.2. They are attached to rings or/and slings. They must be properly tightened so that in lifting condition plate or load should not slip or fall.

All tackles should be thoroughly checked before use.

3.5.3 Safety in Design, Construction and Operation of Lifting Machines and Tackles :

The main requirements are as under :

1. Section 29 of the Factories Act and Rule 60 of the Gujarat Factories Rules require that (1) All parts including the working gear, whether fixed or movable, shall be of good construction, sound material, adequate strength and free from defects, properly maintained and thoroughly examined by a competent person at least once in a year (2) A travelling crane should not be moved within 6 m of any person where he would be liable to be struck by the crane and (3) All rails and tracks shall be of proper size, adequate strength, even running surface, properly laid and maintained and adequately supported.
2. Safe working load (SWL) and distinguishing or identification number should be marked on each lifting gear. A table of varying load and angle should be attached.
3. Heat treatment of lifting gear should be carried out to remove defective structure developed during forging, welding or service and to improve the properties of the material i.e. to increase its strength, hardness, ductility and toughness.

   Rule 60(5), GFR, requires annealing of parts in general use at least once in a year and that of the parts used to lift molten metal or slag or if made of less than 12.7 mm dia, once in 6 months.

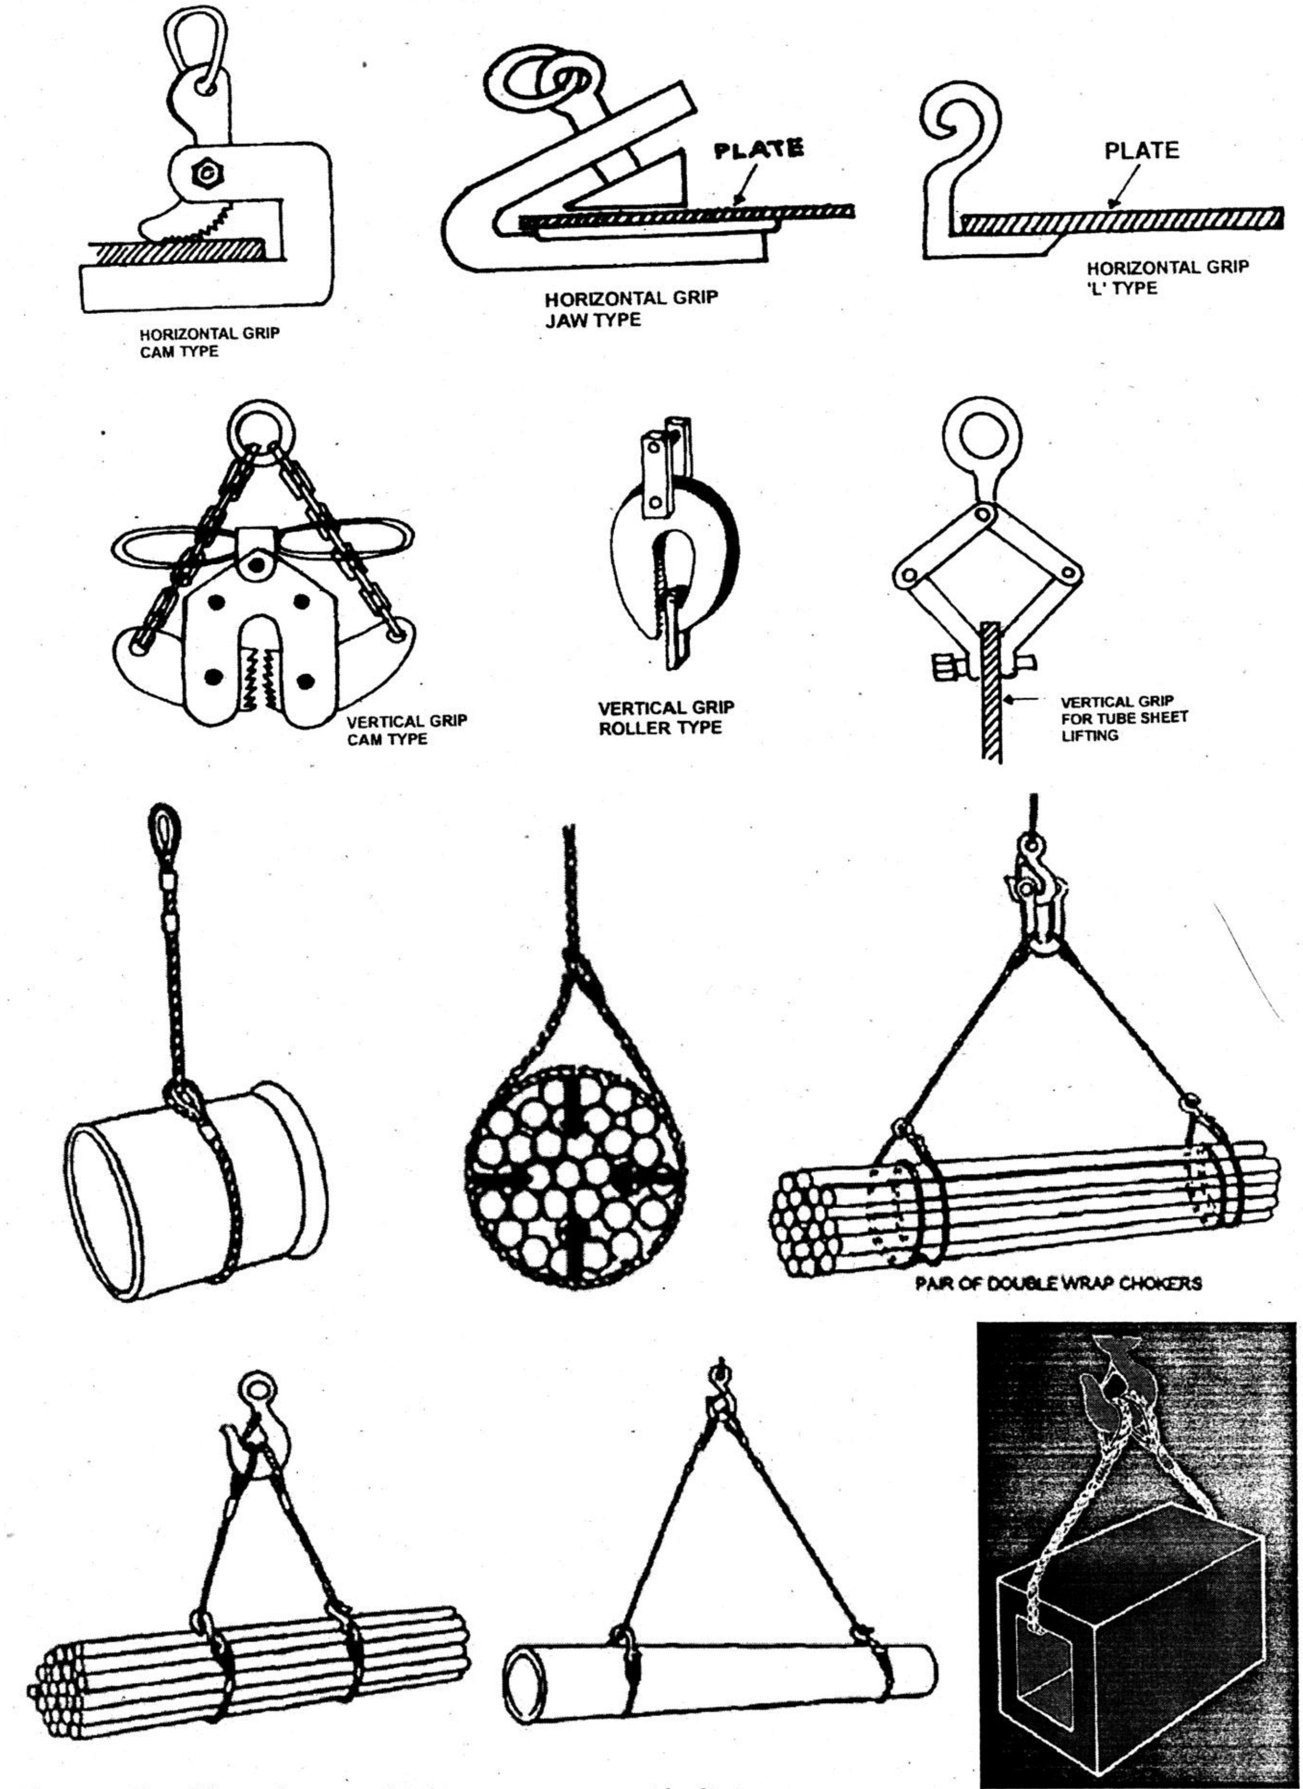


Fig. 15.2. Plate lifting clamps and Lifting arrangement with slings.

4. Chain slings should be selected as per the load requirement. Never decrease the angle between the legs of the chain sling and the horizontal. This will increase load in the sling legs. Pad sharp corners. Lift without jerk. Keep hands and fingers out of the chain and the load. Stand clear of the load when it is being lifted. Don't lift beyond SWL and employ trained personnel.
5. Wire rope is preferable than fibre rope due to its greater strength and durability, no change in physical characteristics and predictable stretch characteristics.
6. There are five basic design elements of a wire rope : Grade of wire. Number and pattern of wires in the strand. Type of lay. Performing and Type of core. Knowledge of these characteristics is useful in selection of wire rope or wire rope slings.
7. The diameter of the pulleys, reels, drums should be large to reduce bending action on the rope.
8. Parts subjected to impact, wear and rough use should be of sufficient strength for its rated service. Bearing pressure of shafts should be within safe limits.
9. Open hooks are unsafe. Spring lock at hook point and guard on load block pulley rope are desirable. Heavy hook should have handle to guide it for slings.
10. Gantry cranes should have rail clamps, parking brakes and wind velocity indicator and alarm.
11. Rated load should be marked on each side of the crane and on each load block (hook assembly) in case of more hoisting units on one crane. The crane shall not be loaded beyond its rated capacity except for testing.
12. Operating levers and control should be within reach of the operator. They should have 'spring returns' to move automatically to 'off position.
13. Platforms, footwalks, steps, hand holds, guard-rails and toe guards shall be provided for safe walking and access ways. Platforms should have non-slip surface. Step gap should not exceed 30 cm.
14. Positive stops or limit switches shall be provided to prevent overrunning the safe limits. Lower and upper travel limit switches should be provided.
15. Lubrication points shall be in safe position.
16. All gears, moving parts, couplings and rope neaps should be totally enclosed.
17. Travelling cranes should have powered and non-powered warning bells. Independent brakes for ' hoisting, traversing, travelling and parking operations.
18. Sheaves and drums should be inspected for wear. Enlarged grooves indicate replacement.
19. The rope end should be firmly anchored to the drum by a socket arrangement and minimum two turns (wraps) of rope should remain on the drum when the hook is at the lowest level.
20. The rated load divided by the number of rope parts should be less than 20% of the nominal breaking strength of the rope.
21. Power shall be shut off and personal padlock or tagging shall be provided before starting any repair or maintenance work. Arrangement should be made to prevent entry of another crane in the zone of crane under repair.
22. DCP, CO, or equivalent fire extinguisher should be kept in crane cabin.

3.5.4 Care, Testing, Inspection and Maintenance of Lifting Machines and Tackles :

Care in design, operation and maintenance of any lifting equipment is utmost necessary. It includes many points some of which are common and some specific points differ with the type of machine.

Some Common Points of Care :

Design	Operation	Maintenance
Appropriate factor of safety. Sound material & Good const.	Trained operator. No loading above SWL. Moving hook load	Periodical tests and certification. Lubrication of parts. Repairs and

Safe design. Marking of SWL & identification. Provision of limit switches, brakes, anchoring, earthing, guarding, means of access, ladders etc.	safely. Use signaling & warning. Raise or lower carefully. Following manufcturer's instruction. Work on or near tracks. No load handling over workers on floor. Safe position at the end of work.	replacement of parts. Daily and periodical inspection. Display of notices and load tables.

Some specific points are mentioned below :

Hoists & Lifts : DOS and Don'ts of safe operation should be followed. Safety devices and interlocking should be well maintained. Regular testing' and examination are necessary.

Lifting tackle or gear : If more than 10% wires are found broken or wear on any stress bearing part exceeds 10% of the requisite nominal dimension or the part shows signs of excessive wear, corrosion or other defects, it should be considered unfit for service.

Testing period of lifting machinery and tackles, prescribed by the Factories Act is one year. A test certificate specifying the SWL is also necessary (Rule 60, Form 10, GFR)

Metallurgical Defects and Heat Treatments :

Ferrous and non-ferrous metals are used to make lifting gear. Monel metal (2/3 nickel, 1/3 copper, small percentage of manganese and iron) is highly resistant to corrosion. Chains and other lifting gear made of monel metal are suitable for use in chemical plants.

Copper is the main constituent in brasses and bronzes. They are mainly used for bearings .in lifting gear.

Aluminium and manganese bronzes have high strength, ductility and corrosion resistance. They are used to make chains and fittings where higher corrosion resistance is required.

During welding process, the adjacent material is subjected to intense local heat and becomes brittle on cooling. Links, rings and chains require heat treatment to correct this coarse structure.

In the process of forging, drop forging steel is highly heated to have desired shape. Then the structure becomes brittle. With hammering or hot work the grain size in the material changes.

Defects are also developed during service. Due to interlink pounding, wrought iron develops surface brittleness. Due to bending strain, link becomes hardened and develops crack. Over a period it results in link fracture.

Internal hardness can develop both in wrought iron and steel gear due to overloading. Improper use causes reduction in ductility. Certain low carbon steels are liable to strain-ageing.

Rings, hooks, links etc. used in a sling must be of the same material and of equal strength as the chain.

Heat treatment (a series of operations involving heating and cooling of metal parts) - Low temperature annealing, normalising, hardening and tempering should be carried out as per requirement.

Heat treatment like normalising or hardening and tempering can restore the strained parts to. original condition provided no crack has taken place. Types of heat treatment are - low temperature annealing, normalising, hardening and tempering. Thus such metallurgical defects should be detected by proper inspection and necessary heat treatment be applied.

Defects and Precautions : Stretch or deformation, excessive wear, cracks, nicks, gouges and corrosion pits- should be searched by proper inspection procedure and removed.

Selection of proper rope and inspection before use are important. Workers should be thoroughly instructed to follow safe operating procedure in using ropes and chain slings. They should be kept away from heat, fumes, chemicals and exhaust gases. They should not be used against sharp edges. Protect them by padding. Observe proper slinging rules. Do not exceed safe slinging angles. Check for friction heating for fibre ropes.

No tackle should be dropped from heights. They should be stored in clean dry place.

Inspection of Tackles:

Normal inspection periods are as under:

Device	Period
Hoisting and lowering wire rope	3 months
Wire ropes with broken wire	1 month
Cranes and attachments	12 months
Thorough inspection of all parts of crane	3 years
All other lifting machinery	12 months
Half inch and smaller gear	6 months

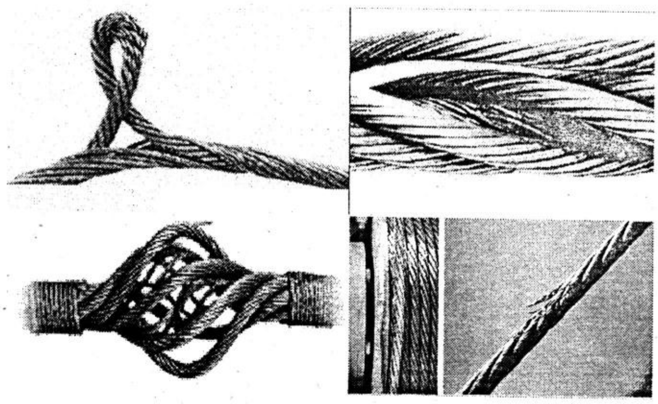
All items used in lifting machinery should be subjected to proof test loads (see Part 3.3.3) and after the test, they should be thoroughly examined by a competent person for signs of cracks, fatigue, deformation, stretch etc.

Hooks must be removed from service if they have opened outmore than 15% of the normal throat opening, measured at the narrowest point or twisted more than 10 degrees from the original plane of the hook. The bent hook should not be straightened and reused.

A locking pawl prevents the load to come out from the hook.

Fibre ropes should be inspected before use every time. Broken fibres, yarns, cuts, nicks, abrasion, unlaying and reduction in diameter are the main defects. If the fibres pulled from the rope breaks, it shows brittleness and need to replace the rope.

Wire ropes should be inspected for broken wires, torn, flattened and abraded wires, reduction in rope diameter, rope stretch, corrosion, kinks, crushed or jammed strands, bird caging and inadequate splices



New lubricants, free of grit should be applied on wire rope to penetrate internally as well as to coat the external surface.

Defects in wire ropes are : broken wires, worn and abraded wires, reduction in rope diameter, rope stretch, corrosion, kinks, crushed, flattened or jammed strands, bird caging and damaged splices. In such cases new wire rope should be used.

The visible broken wires should not be more than 5% of the total wires in a length of 10 rope diameter. Wear on the surface of the rope should not be more than 1/3 of the diameter of the wire. In pendants or stranding ropes, there should not be more than 3 broken wires in one rope lay.

Rope stretch should not be more than 15 cm per 30 m length in the six strand wire ropes. Rope should be discarded if more than 20 breaks appear on a rope lay.

Reduction in diameter of the rope due to core failure, abrasion etc. should not be more than
1.0 mm for ropes upto 19 mm dia
1.5 mm for ropes of 22 to 28 mm dia
2.0 mm for ropes of 32 to 38 mm dia

Chains : Most of the causes of chain failures can be detected before they occur if proper procedure is followed. Frequency of such inspections depends on service conditions. Normal defects are (1) stretch or deformation (2) excessive wear (3) cracks (4) nicks and gouges and (5) corrosion pits.

Chains are to be checked for crack, corrosion and pitting. More than 10% wear at their two-link-touching point render them unfit for use. Avoid jerks and impact loads. Never re-weld alloy chain links. Avoid crossing, twisting, kinking or knotting a chain.

Causes of chain failure are defective welds, defective metal and overloading. All chains should be thoroughly inspected link by link by a competent person. After shock or impact loads, it must be immediately inspected. It is an unsafe method to use the broken chain by inserting a bolt between two links.

Clean the chain thoroughly in a solvent solution. Lay it on a clean surface. Use magnifying glass to look for stretched links, wear, crack, corrosion and pitting, bent, twisted or damaged links. If stretch (elongation) is more than 3% the chain should be discarded. Elongation should be measured between fixed length of 10 or 20 links.

When the dia of the link is reduced due to wear and tear, SWL shall be reduced as under :

Normal chain link dia (mm)	**When the dia at worn section is as under (mm), reduce rated capacity by**	**Remove from service when dia**

	5%	10%	(mm) is or lower
6	5.75	5.70	5.40
9	8.78	8.55	8.10
13	12.68	12.35	11.70
16	15.60	15.20	14.40
19	18.53	18.05	17.10
22	21.45	20.45	19.80
25	24.38	23.38	22.50

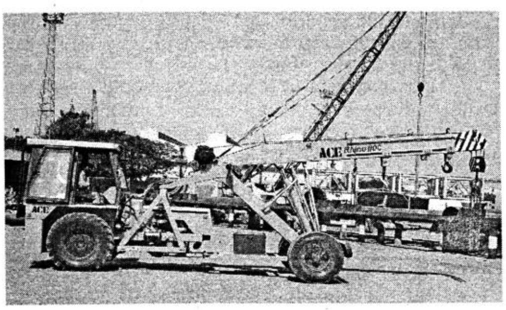
Shackles worn more than 10% of the original diameter in crown or the pin should be replaced. Pins should not be bent. Shackles shall not be pulled at an angle because it will reduce its capacity.

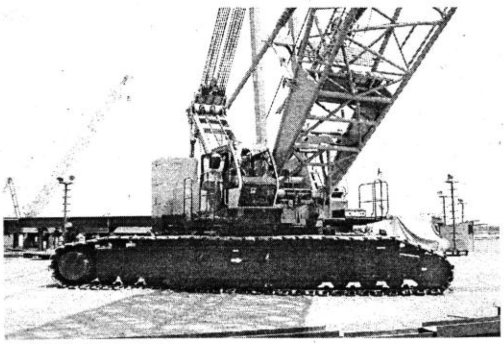
Chain pulley blocks of proper lifting capacity should only be used. They should be lubricated before every use. No alteration should be done on chain blocks. They should be tested for slip by suspending safe load. The chain should not come out of pulleys. The anchorage should be strong and rigid. Opened out hooks should not be used. Chain block/puller must be checked if stored for a long time, by subjecting to shock load, to observe slipping of load, jamming on links etc.

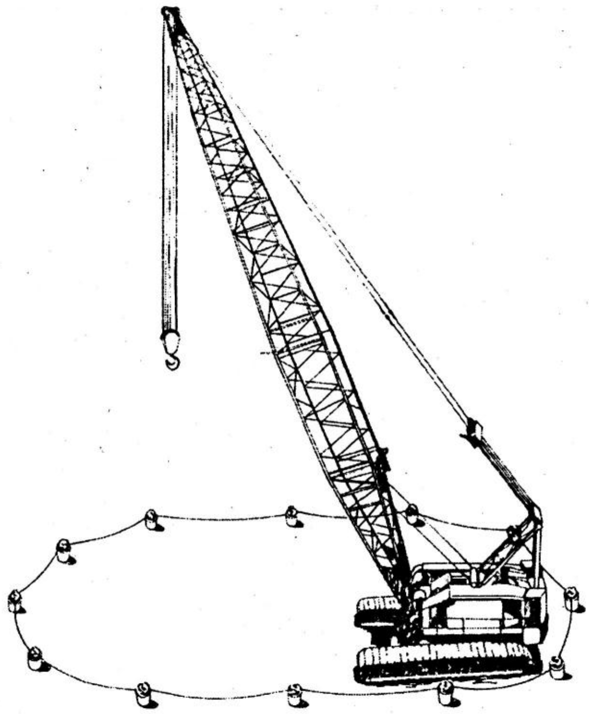
Winches should be placed on a firm base and properly anchored. Brake, ratchet arrangement, gear and pinion including meshing, wire rope and its clamping arrangement, direction of receiving rope drum and tie rods should be checked before using any winch.

Derrick - The mast, guy-ropes, wire ropes, swivel hook, rope clamps etc. should be thoroughly checked before erecting the derrick. Its lifting capacity should be ascertained by a competent person and it should not be overloaded. Guys of the derrick should be anchored tightly with strong structures, hold fasts, anchorage blocks etc. Welded parts should 'be periodically checked for any crack or defects in metal itself.

Mobile Cranes should not be used on a slope unless adequate precautions are taken to ensure stability.







SWL of cranes apply only when they are installed on a level, firm and uniform surface. Crane stability is reduced when operating on a slope. Therefore level must first be checked. It is dangerous to lift a load with 2 cranes and should be avoided unless a single crane of the required capacity is unavoidable. Trapping or striking with persons should be avoided. A crane should not be left unattended.

Jib or boom of a mobile crane should not touch any electric wire or loose construction which may fall. When any overhead material handling work is going on, simultaneous work down below must be avoided to eliminate risk of being hurt by any falling material.

Mobile cranes should be parked on hard soil or strong base. Tag lines should be used while hoisting heavy and bulky materials. The brakes, boom, hook, wire ropes, pulleys and rope anchoring should be checked periodically by a maintenance man to ensure the safe operation. Required derating should be done in case of any defects found and it should be formally made known to all concerned.

In case of a mobile crane, the load shall be derrick out while going up a gradient and the load shall be derrick into the minimum radius while going down:

Mobile cranes are to be tested for (1) A dynamic test of 10% overload (2) Test with 25% overload and (3) Static stability test.

All control mechanism, safety devices, hydraulic system, hooks, running ropes and electrical apparatus of a crane should be inspected frequently for malfunction, wear, deformation crack, fluid leak, dirt and moist accumulation etc.

Defects to be checked in a crane are

1. Deformed, cracked or corroded members of crane, structure and jib.
2. Loose bolts or rivets.
3. Cracked or worn sheaves and drums.
4. Worn or damaged pins, bearings, shafts, gears, rollers etc.

5. Excessive wear on brakes or clutch parts, linings, panels and ratchets.
6. Diesel, electric or other power units for improper performance.
7. Excessive wear on chain drive, sprocket and excessive chain stretch.
8. Travel, steering, braking and locking devices for malfunction and
9. Excessively worn or damaged tyres.

During repair and maintenance, permit to work system should be followed. A preventive maintenance programme, based on the crane manufacturer's recommendations should be established.

All moving parts should be regularly lubricated and lubricant level should be checked.

Crane operators should be of more than 18 years age and properly trained, medically fit with regard to eye sight, hearing and reflexes, and understand fully the duties of die slingers and be familiar with the signal code.

Documentation for record of inspection and maintenance and test certificates is equally important.

3.5.5 Safe Location :

Safe location or storage of lifting tackles is necessary.

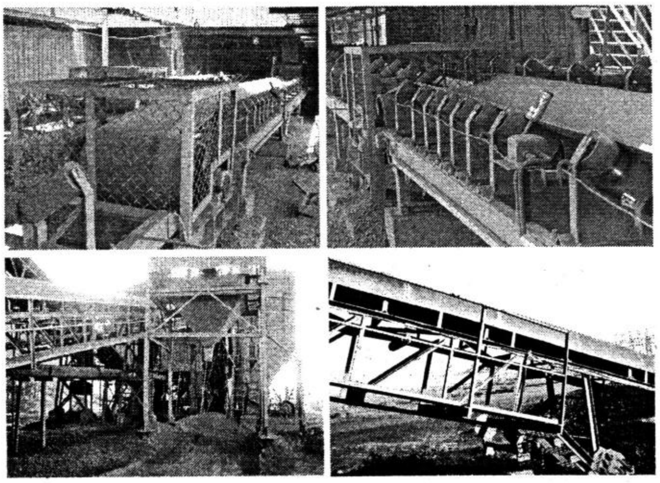
Proper storage of chains will impress the workers the need for proper care at: all times. The chains should be hung on racks in dry air and normal temperature to prevent rusting. Racks should be so arranged that no worker should be exposed to lifting hazards. Heavy chains may be stored in neat piles on a rack surface. Dampness, darkness and corrosive atmosphere should be avoided.

Slings should be kept on suitable racks or pegs when not in use. SWL should not be exceeded as a result of the angle between the legs.

Store the ropes in a cool, dry room having good air circulation. Hung the ropes up in loose coiled in pegs. Clean the rope after use and dry them before storing. Fibre ropes should be protected from pests, rats, sun, weather and dampness.

3.6 Conveyors & their Safety Features:

For moving material, normally two types of equipment are used. Conveyors are used when the path is fixed and industrial trucks are used when the path is free.



Various types of conveyors and mono-rail systems are used in many industries to eliminate manual labour, to expedite the movement of materials and also to facilitate the processing or assembling. Belt conveyors are widely used and they are of flat or trough type and can be horizontal or inclined. They are used for handling almost all the materials of modern industry including coal, coke, grain, fertilisers and building materials such as sand and gravel. Some important safety measures are :

1. Conveyors shall be so constructed and installed as to avoid hazardous points between moving and stationary parts or objects. Gears, sheaves, sprockets and all moveable parts shall be securely guarded.
2. Where workers have to cross over conveyors, regular crossing facilities affording safe passage and adequate lighting shall be provided. To cross underneath, at least 7 feet headroom is required. Crossovers should be with bridge, stairs and handrails.
3. Conveyors shall be provided at loading and unloading stations and at other convenient places with devices (pull wire) for stopping the conveyor in emergency. A pull wire at intervals of 8 m should be provided.
4. When two or more conveyors are operated together, the controlling device shall be so designed that no conveyor can feed on to a stopped conveyor. This may be interlocked.
5. Where conveyors extend to points not visible from the control station, they should be equipped with gongs, or signal lights to be used by the operators before starting the machinery so as to warn persons who might be in position of danger.
6. Conveyors shall be provided with automatic and continuous lubrication system or with lubricating facilities so arranged that oiling and greasing can be performed without the oilier coming into dangerous proximity of the moving parts. Scrappers should be provided to remove sticky material.
7. Workers should not ride on conveyors.
8. For repair/maintenance work, power must be totally stopped and danger-tag should be displayed. Belt cleaning by flammable solvent should be avoided.
9. Tension pulley - nips. and idler rollers should have fixed guard on their complete length of movement.
10. Moveable dead/counter weights should also be similarly guarded.
11. Static charge collectors should be provided close to the outrunning sections of the drive pulleys and idlers.
12. Elevated conveyors should have walkway with toe board (10 cm) and hand rail (I m) all along the length. Flooring should be non-slip type, particularly on sloping walkways. Handrail should also be provided on the belt side. Stop cord must be within easy reach.
13. Underpasses should have firm ceiling. Guards should be provided below all conveyors passing. over roads, walkways and work areas.
14. Conveyors running in tunnels, pits etc. should be provided with sufficient lighting, ventilation, drainage, guards, escape ways and maintenance clearance.
15. If a hopper is used at floor level to feed conveyor, the grill or guard should be provided to prevent falling of a person inside. Scrapper may be provided between the hopper bottom and the moving conveyor. This will restrict the excess flow of material and alert any person under passing it.
16. If two or more conveyors operate in series, it should be so interlocked that if one conveyor stops, all conveyors feeding it are also stopped.
17. In case of reversing or running away possibility, anti-runaway and backstop devices should be provided so that the load cannot slide or fall in the event of mechanical or electrical failure.
18. Overload stop devices like slip or fluid couplings and shear pins are desirable.
19. The loading and discharge points of powdered material on conveyor should have exhaust hood for dust removal.
20. If the material is combustible, the dust concentration should be below LEL, electric fittings should be flameproof, the conveyor should be grounded and its parts bonded to prevent differences in

electric potential. The container into or from which the material is conveyed should also be similarly grounded and its parts bonded.

21. Tight fitting clothing, safety shoes, goggles in dusty area and respirators are useful equipment.
22. Before starting maintenance or repair work, power should be locked in 'off position with key in pocket. It should be tagged also with 'not to start' notice.
23. Fixed scrappers or revolving brushes to remove sticky material from drum or pulley eliminate need of hand operation.
24. Static charge collector should be placed nearer to the outrunning sides of the drive pulleys and idlers.
25. Operators should be trained in safe work procedures near belt conveyors. They should be trained to avoid pinch points to save their hands and fingers.

Other types of conveyors are gravity conveyors either chute or roller type; screw conveyors (mostly used in cement, coal pulverising, pottery and grain plants), power roller conveyors, overhead chain conveyors (to transport material from place to place) bucket conveyors and aerial cableways.

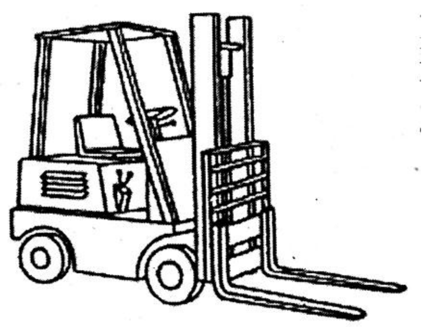
Screw conveyors should be covered at all times and the cover should not be opened without stopping the conveyor, or it should be interlocked. Buckets of conveyor should be enclosed throughout their length. Guard rails should be provided at picking point.

Pneumatic conveyor use air pressure or vacuum to push or pull the material in tube or ducting. Noise insulation is required at high noise points (mostly bends).

3.7 Industrial Trucks:

Power trucks usually operate by petrol, diesel, LPG i.e. by internal combustion engine or dry cell batteries and are extensively used in factories for handling of materials to and from stockpiles, to and from machines and through warehouse or loading platforms. They carry, lift, push, pull, stack and tier material. These trucks are of many types, such as fixed platform, elevating platform, forklift, motorised hand truck controlled by a walking operator, electronically controlled without operator i.e. Automated Guided Vehicle (AGV), straddle trucks, crane trucks etc.

The elevating type of platform is inserted under the skid elevated to lift it from the floor and the truck carries it to some other point. Each truck needs overhead guard to protect its driver.



The forklift truck makes the lift by means of a two prong fork instead of a platform and lifts the load up from the floor permitting high piling to conserve space. They could also be fitted with special attachments for handling barrels, paper reels, etc.

Safety precautions to be observed in operation of forklift trucks are:

1. The capacity of every lift truck should be marked on the truck and they should not be overloaded.
2. Loaded or empty forks should be carried as low as possible but high enough not to strike a ramp.
3. Care must be taken to avoid jerking when tilting a load forward or backward, specially when the load is at a height.
4. Personnel must not be allowed to ride on the forks.
5. Forks should be driven well under the load, preferably full length or at least 2/3 of the length.
6. When there is a danger of falling objects over the operator, canopy overhead guard should be provided.
7. Aisles, floor etc., should be maintained in good condition including proper lighting.

8. Mirrors at turning points (corners) to avoid front collision of two fork lifts coming in opposite direction.

Other operational safety precautions for all types of power trucks are :

1. Selection and training of the operator. He should be provided with DOS and Don'ts of the operation, specialties of the work situation and layout, plant rules, manufacturer's instructions etc.
2. While travelling, fork should be in lowered position and it should not be moved for tilling, lowering or lifting.
3. Lift trucks should be driven in the reverse direction when the load obstructs the vision or while coming down from ramps or slopes.
4. If any rail track is to be crossed, it should be done diagonally and not at right angles.
5. Before crossing a bridge, plate operator should make sure that it is properly secured.
6. Operators should be instructed –
   (1) not to carry persons on the truck.
   (2) to check the conditions of the vehicle before starting e.g. tyres, brakes and safety devices.
   (3) not to leave the truck on aisle space, and to park at the place allocated. Parking brakes should be applied. Power should be shut off.
   (4) not to turn a truck on a gradient.
   (5) not to carry out unauthorised repair or adjustments.
   (6) to notify defects known by them.

OSHA prescribes detailed safety rules for power truck operation.

Built-in-safety features are overhead guard on driver's seat with visibility, static and dynamic load test for overhead guard, overload warning devices, control levers, stability test, brakes test, forks load test for 3 times the rated load per fork, lifting chain load test for 5 times the rated load.

Load backrest extension, tiers guard, guards on chain, sprocket, gears etc., name plate with capacity, horns & flash light - are also required.

Other power trucks such as reach truck (carrying load under wheel base), side loaders (forklift trucks with side forks), picking trucks (to pick up material at different places from storage racks), pallet trucks (with forked platform mounted on small wheels to go under a pallet), platform trucks, tractor-trailer train, straddle trucks, straddle carriers and driverless electric trucks may be used as per requirement and should use specific safety precautions.

Inplant truck routes should be identified with markings e.g. width of aisleways, gangways, crossing for traffic, signs for narrow width of height etc. Blind corners and turns should be avoided.

Special precautions to drive trucks in flammable areas need necessary approval of a qualified person, area monitoring, mufflers on exhaust pipes etc.

Regular inspection and maintenance of power trucks should include checking of lights, brakes, battery, horn, lift system (fork chains, cables and limit switches), steering, controllers etc. and using wheel block and brakes while loading, unloading or any maintenance work.

Safety points for powered trucks should include three sections as under :

1. **Safe Operating Conditions :** The floor, storage and stacking areas, width of stacking aisle, lighting, loading and unloading areas, ramps and slopes, battery charging areas, pedestrians,

selection of proper size, type and capacity of truck, its maintenance and guards and view mirrors for the driver.

2. **Hazards in truck operations :**

(1) Overturning due to-
sudden braking, wheels striking obstruction, use of forward tilt with elevated load, driving down ramp with load preceding truck, striking overhead obstruction when reversing, turning on or crossing ramps, load shifting, wheels sinking into unsuitable floor or ground and overloading.
(2) Collisions.
(3) Floor level hazards - gullies, pot holes & debris.
(4) Overhead obstructions like pipes, cables and fixtures.
(5) Load unbalancing and falling.
(6) Truck failure due to brakes, steering, chains, hydraulic system, condition of forks, other attachments, horn, wheel nuts, tyres, electric wiring insulation, fuel supply systems on i/c engine trucks, cleanliness of power unit i.e. free from dust oil etc.
(7) Explosions and fire due to hydrogen while charging, contact of live cables with the' truck frame and shorting of battery terminals by metal tools or lifting tackle. Battery terminals should have suitable insulating covers.
(8) Carrying passengers without suitable seats.

3. Safe Operating Techniques and Training : All truck operators must be trained for safe driving and operating methods and matters stated in para I & 2 above.

See fig. 15.3 for different types of lift trucks.

3.8 Training of Operators :

See Rule 60(8) of Gujarat Factories Rules, 1963.

Proper selection and training of operators for any lifting equipment and power trucks are the most essential. The operators should be of more than 18 years of age, medically fit with regard to eyesight, hearing, reflexes and driving requirement and should have experience and attitude to operate the equipment safely. They should be fully trained to drive and operate the equipment with better judgement of distance, height, depth, clearance and turning. Knowledge of working of the equipment, routine checks and maintenance methods, signal code, colour code, hazards of materials and their handling should also be given.

Any safe equipment may be unsafe in untrained. hands. Therefore good training of all operators for mechanical handling is more important to prevent accidents due to material handling.

Each plant should devise rules for operators depending on types of industrial trucks provided, types of material handled, plant layout and type of environment.

Initial and refresher training should be given to truck operators. Such training programme should also consider types of truck accidents and losses already happened, operating habits of operators, properties of materials to be handled, faults and repairs with vehicles, filling of operator's daily reports, other performance forms and inspection and maintenance log. National Safety Council, USA has designed such forms. See reference No. I at the end.

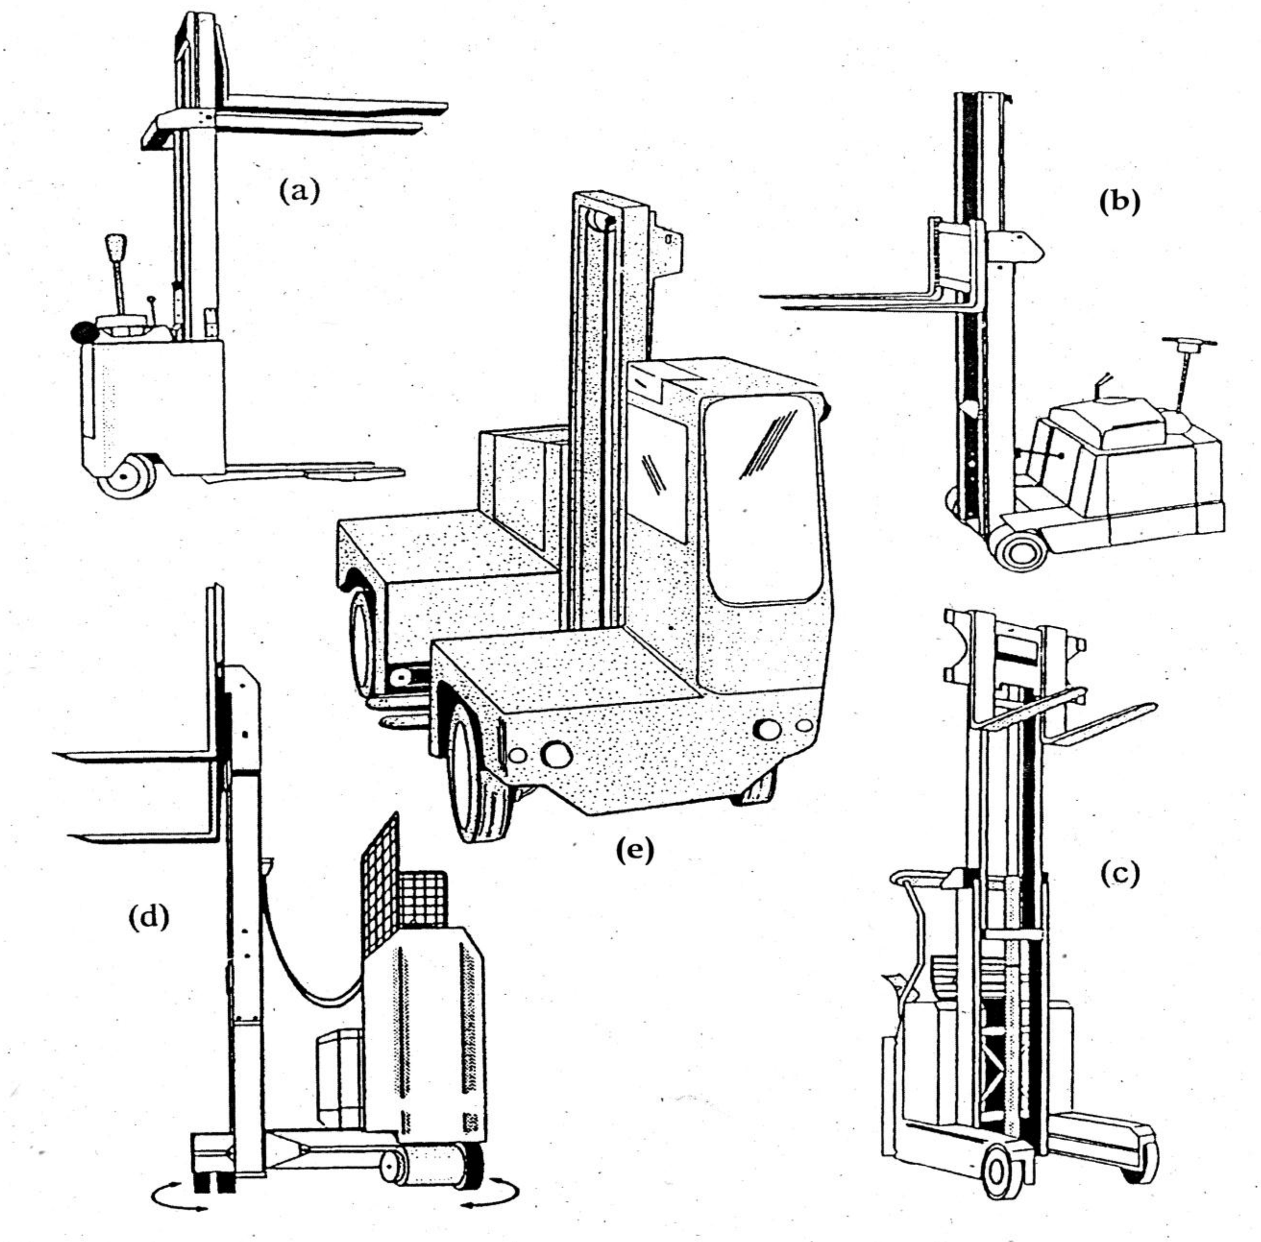


Fig. 15.3 Lift Trucks : (a) Pedestrian Pallet Stacker; (b) Pedestrian Counterbalanced Truck; (c) Reach Truck; (d) Four-directional Truck; (e) Side Lodading Truck.

Nine most common forklift truck accidents described by Theodore H Allegri in his book (mentioned as Reference No. 9 at the end) are as under:

1. Employee struck by forklift truck.
2. Forklift throws load on employee standing between the forklift truck and a fixed object.
3. Operator struck by falling parts while manually handling materials.
4. Operator or other employee is injured while boarding or stepping down from the forklift.
5. Operator fails to recognise serious hazard ahead and fails to slow down the truck.
6. Vehicle runs into other moving vehicles.
7. Vehicle backs or runs off the edge of the loading dock.
8. Part of operator's body protruding outside the running lines of the truck.
9. Parts fall on the operator.

Three main causes mentioned are :

1. Lack of knowledge or skill.

2. Operator being inattentive to the job.
3. Operator taking chances with full knowledge of the possible consequences.

Therefore an accident reduction programme should include

1. Provision of quality training.
2. Inclusion of follow-up into every programme.
3. Control of safe work practices.

3.9 Competent Persons, their Duties & Responsibilities :

Section 28(1) of the Factories Act requires that every hoist and lift shall be thoroughly examined by a competent person at least once in 6 months and a register in Form No. 9 (u/r 58 GFR) shall be maintained.

Section 29(1) of the same Act requires that lifting machines and tackles shall be thoroughly examined by a competent person at least once in a year or at an interval specified by the CIF. The record shall be kept in Form No. 10 (u/r 60 GFR).

For a competent person 7 years experience is required after B.E. (Mech. or Elect.) to test and certify hoists and lifts (Rule 2A GFR).

For lifting machines and tackles, B.E. (Metallurgy) is also allowed.

Duties expected by the competent person include load testing, heat treatment and checking of safe working conditions. Facilities for such work should be available at his workshop.

The thorough examination means visual examination, hammer test, detection of cracks, porosity and other damage and by dismantling the parts in order to arrive at a reliable conclusion as to the safety of the parts.

Duties of the Competent Person :

1. To study the provisions of the Factories Act, Rules and other statutes pertaining to hoists, lifts, lifting machines and tackles.
2. To study Indian Standards and other relevant Codes for design, operation, maintenance, testing and certification of material handling equipment.
3. To go on call to the manufacturers and users of the material handling equipment to test and certify them.
4. To keep ready the necessary load testing, heat treatment, NDT and other equipment to test the machine parts.
5. To keep ready the necessary statutory forms to be filled after the statutory examination or testing.
6. To report the defects to be rectified to the user/ customer and to the concerned authority.
7. To test and certify again after the rectification of the defects previously notified.
8. To get renewed the certificate of competency issued by the authority. .

Responsibilities of the Competent Person :

1. To calculate the SWL where it is not available.
2. To prepare a table of SWLs and load angles in case of a jib-crane or multiple sling - where SWL varies at different angles of the jib or legs and to display near the machine.

3. All hoists, lifts, lifting machines and tackles shall be thoroughly examined and tested and a certificate in the prescribed form (No. 9 for hoists and lifts and No. 10 for lifting machines and tackles) shall be signed specifying the SWL and defects found if any, and given to the user.
4. Different types of load tests including deflection test of an overhead travelling crane shall be carried out and certified.
5. Different types of defects shall be ascertained and remedial measures shall be suggested to remove them.
6. Defective parts (lengthened, altered or repaired by welding or otherwise) shall not be used again unless it is adequately tested, examined and certified in writing by him.
7. Annealing (low temperature heating and cooling) process shall be carried out under his supervision (1) at 6 months interval, of the parts made from a bar of 12.7 mm or smaller diameter or being used to handle molten metal or slag and (2) at 12 months interval, of all other parts in general use.
8. Any chain or lifting tackle subjected to normalising (instead of annealing) shall be thoroughly examined by him at, 12 months interval and particulars of such examination shall be entered in Form No. 10.
9. To attend an office of the authority or court, on call, in connection with any examination/test carried out by him or certificate given by him To obey the instructions given by the authority who issued him a certificate of competency, for the purpose of safety.
10. He should notify the serious defects and safety measures pointed out by him in relation to specific cases where a testing period needs to be decreased and intervention of the CIF is necessary as prescribed in Section 29 (l)(a)(iii of the Factories Act 1948 or where a serious concern from safety point of view is involved See also Part 6.8 of Chapter-6.

E X E R C I S E

1. Explain, State, Mention or Discuss :

1. The need of safety in material handling
2. Kinetics of Manual material handling.
3. Safe method of manual lifting of load. Draw sketch.
4. Health hazards of manual material handling.
5. Safety precautions for manual handling.
6. Safe work methods for lifting and carrying of different objects.
7. Safe methods of using accessories for manual handling.
8. Safe methods of storage of pipes, bars and long objects OR of Metal sheets and plates.
9. Handling precautions of hazardous materials.
10. Points of consideration in stacking and unstaking.
11. Floor and lay-out conditions for material handling.
12. The ergonomics of manual handling.
13. Safety provisions under the Bombay Lifts Act or the Gujarat Lifts and Escalators Act.
14. Different mechanical equipments and lheir uses for material handling.
15. Meaning and usefulness of Safe Working Load.
16. Meaning and usefulness of Proof Load.
17. Types of heat treatment and their uses in regard to lifting machines and tackles.
18. Points of care and maintenance of lifting machines and tackles.
19. General requirements of design, construction and operation of lifts and hoists.
20. Specific safety aspects of Lifts or Escalators
21. Types of lifting machines and their safety aspect.
22. Types of lifting tackles and their safety aspect.
23. Safety requirements in design, construction and operation of lifting machines and tackles.
24. Inspection check points for tackles.
25. Safety features of conveyors.

26. Safety precautions while using a fork lift.
27. Duties and responsibilities of Competent Persons with regard to lifting machinery.
28. Subjects for training to operators of lifting machines and tackles.
29. How much load is considered a safe load in manual lifting of load?
30. How will you safely handle or use following items?
    (1) Crow bar (2) Carton box (3) Bromine bottles (4) Acid carboy (5) Gas cylinder (6) Ladders (7) Fork lift (8) Jib crane (9) Hook (10) Oil drum (II) Bridge crane (12) Glass sheets (13) Piling of cotton bales (14) Multi chain sling (15) Gravity conveyor.

2. Write Short Notes on :

1. Hazards of manual material handling.
2. Hazards of mechanical handling.
3. Maximum limits of loads to be lifted as per GFR.
4. Body injuries due to manual handling.
5. Kinetic method of lifting a load.
6. Team work in lifting a load.
7. Safe use of rollers OR hooks.
8. Storage of barrels and drums.
9. Storage of paper reels OR Gas cylinders.
10. Methods of safe stacking
11. Classification of material handling process and equipment.
12. Transport equipment for material handling.
13. Derricks.
14. Chain Pulley block.
15. Safety devices for a lift.
16. Lifting gear.
17. Marking of SWL.
18. SWL of a mobile crane.
19. SWL for fibre ropes, wire ropes and slings.
20. Mobile Cranes.
21. Defects in wire ropes and chains.
22. Testing, inspection and maintenance of lifts and hoists.
23. Signalling.
24. Inspection and testing of heavy duty EOT crane.
25. Precautions while using slings.
26. Metallurgical defects in tackles.
27. Causes of chain failure.
28. Inspection of wire ropes.
29. Inspection of chains.
30. Defects to be checked in a crane.
31. Safe location of Lifting tackles.
32. Types of fork lift accidents and their preventive measures.
33. Thorough examination.
34. Built-in-safety features of a fork lift.
35. Hazards ,in industrial truck .operations.
36. Types of ropes OR Slings.
37. Types of conveyors. .
38. Norms for discarding wire ropes OR chains.
39. Different material used to make lifting ropes and their merits and demerits.
40. Operating practices for slings.

3. Explain the difference between :

1. Manual handling and Mechanical handling.
2. Individual lifting and team lifting.
3. Use of hand truck and use of hand trolley.
4. Use of hook and use of jack.
5. Hoist and Lift
6. Lifting machines and Tackles.
7. Sling and Ring.
8. Shackle and Swivel.
9. Jib crane and Gantry crane.
10. ETO crane and Mobile crane.
11. Monorail and Winch.
12. Belt conveyor and Screw conveyor.
13. SWL and Proof Load.
14. Defects in hook .and defects in fibre rope.
15. Duties and Responsibilities of a Competent person.
16. Passenger lift and Goods lift.

4. Comment on following explaining whether it is true or not?

1. Material handling does not add to the value of the product but adds to the cost of product.
2. It is not practicable to fix the same limit of maximum load for all persons.
3. Persons of same age cannot lift the same maximum load.
4. Statutory limits of maximum load are necessary.
5. Back pain is possible due to manual lifting.
6. If one person lifts 50 kg, four persons together can lift 200 kg load.
7. Workers should be trained for correct manual handling.
8. Chain requires quality marking while chain sling requires SWL marking.
9. Stress in leg of a sling increases as leg angle with horizontal increases.
10. Any safe equipment may be unsafe in untrained hands.

CHAPTER – 16

Working at Different Levels

THEME

1. WORKING AT HEIGHT

Most of the fall accidents happen while working at height and most of them prove fatal. Therefore seriousness of fall accidents should be considered seriouslly.

1.1 Incidence and Seriousness of Fall Accidents

People are subjected to two types of falls, ethical fall and physical fall. Both are serious and need prompt prevention for the safe elevation of life. Accidents due to ethical falls spoil the self as well as the society and are much more in number than the physical falls which generally affect the person concerned only. This is just a comparison and we are, here, concerned with a narrow range of physical industrial falls only:

Incidences:

Table 5.7 in Chapter-5 states that there were 2.26% fatal accidents due to persons falling from height in India in 1995. Table 5.8 reports 82 fatal and 3950 non fatal industrial accidents due to persons falling in India in 1991. It also reports 33 fatal and 4706 non fatal industrial accidents due to falling bodies in India in the same year.

Table 5.20 gives fatal accidents in Gujarat. It points out that fatal accidents due to falling from height and struck by falling bodies were 25 and 11 respectively, out of 192 fatal accidents in 1995. This represents 13% and 5.7% respectively and the total of causes No. 10, II & 12 indicates 64 out of 192 i.e. 33.33% fatal accidents in 1995.

Table 5.22 gives total accidents of Gujarat in 1994. In its last row, total of causation No. 125 to 128 gives

2298 out of 15683 i.e. 14.65% accidents due to (1) Struck by falling bodies (2) Falling from height (3) Falling on the flat and (4) Falling into pits etc. These are the main types of fall accidents.

As reported in 'Accidents Facts, 1997' by NSC, USA, fatal fall accidents were 15% in-USA in 1996. It was 4% increase from 1995 and this fall death rate was 5.3 per I lac population.

Industrial fatal fall accidents were 573 out of 6210 (9.22%) 'in 1995 in USA. Deaths due to struck by objects were 546 nearly the same.

Non fatal occupational injuries due to falls in 1995 in USA are reported in percentage as under :

Type of Fall	Manufacturing	Private Industry	Construction
To same level	7.4	11.0	7.4
To lower level	3.1	5.1	11.9
Slips & Trips	2.4	2.9	2.6

All deaths (occupational plus non-occupational) due to falls in USA are reported asunder :

Type of Fall	1994	1993	1992
On of from stairs or steps	11563	1087	1197
On or from ladders or scaffolding	327	301	298
From or out of building or structure	477	509	513
Into holes or floor opening	93	107	99

Courtesy : Accidents Facts, 1997, NSC, USA

Figures of Fatal Industrial fall Accidents in UK are as under:

	1978		1979	
	No	%	No.	%
Falls of persons	30	16.2	28	15.6
Falls and movement of other objects.	18	9.7	17	9.5

Figures of National Safety Council, 1987, USA, as given by Willie Hammer, are 16.4% due to falls and 25% due to struck by or against objects.

All these data of India, UK and USA conclude that fall accideilts contribute @ 10 to 20% fatal and @ 12 to 30% nonfatal accidents.

1.2 Types, Causes and Control of Fall Accidents

Types of Falls:

Falls and accidents due to falling objects can be classified as under:

(A) Falls of Persons :

1. Falls from height viz. structure, floor, ladder, scaffold, platform.

2. Falls into depth (negative height) viz. wells, pit, sump, silos, ground opening, tank, vessel, excavation, ditches.
3. Falls on the same level viz. falling or slipping on the floor or flat at the standing level.

(B) Falling Objects (bodies):

1. Falls of objects from height viz. tools; machine part, equipment, material.
2. Falls of objects from the hands of the same person viz. tool, equipment, material being handled.
3. Structural collapse viz. wall, building, ceiling, pipe, ladder, scaffold, beam, truss.
4. Material collapse viz. falling of piles of goods, layers of begs, cloth, paper rolls, carton boxes, grain, cement and fertiliser.
5. Slides and cave-ins viz. earth, rock, sand, stones, snow, ice.

Most serious accidents due to falls and struck by falling bodies take place in mining and quarrying, building and construction, structural repair, alteration, cleaning, painting, demolition, maintenance and unsafe use of lifting and other equipment.

Major causes of such accidents are makeshift arrangement, unsafe floor, unsafe work practices, not using helmet, safety belt, safety shoes, unsafe use of vehicles, poor supervision, poor lighting etc.

Common Causes of Falls are :

1. Water, oil or grease not cleaned up.
2. Loose, defective or broken floor or toe board.
3. Scrap, chipping, swat and obstructions lying on the way.
4. Dusty, steamy or smoky atmosphere restricting vision.
5. Carrying too much load making it difficult to see over the load.
6. Warn out or unsuitable footwear.
7. Poor lighting, glare or shadows. .
8. Rushing instead of walking.
9. Defective or weak scaffolds.
10. Ladders, ramps, planks and platforms not rigid or safe for the job.
11. No or inadequate handrails.
12. Climbing oddly instead of using ladder.
13. Throwing instead of lowering tools or materials while working aloft.
14. Not using spectacles for clear vision.
15. Not using crawling board on fragile roof.
16. Not using a safety belt or using in a wrong way, e.g. not tying its free-end or tying it with a weak support.
17. Not closing the manhole cover or floor opening etc.
18. Allowing roof work and floor work at a time in the same vertical plane.
19. Touching of crane boom, hook etc. to weak or unfastened structure.
20. Non-compliance of statutory provisions.

Most of the falls from height prove fatal or result in serious fracture. Therefore their prevention or control is utmost necessary.

Control Measures for Fall Accidents :

1. Safe, sound and dry (non-slippery) surfaces for walking and working. Fencing, guarding and toe boards.
2. Safe helmet, safety belt, foot-wear, etc.
3. Safe practice in walking and working. No excessive load lifting.
4. Safe means of access while working at height or depth.
5. Use of crawling board, cat ladder, fall arrester net etc. while working on fragile roof.
6. Use of Safety work permit for working at height or depth.
7. Safe and sound stairs, ladders, scaffold etc. and safe use thereof.
8. Good lighting and supervision, cutting off power supply in overhead electric lines.
9. Safety cordon to disallow persons in the area where any object may fall from height.
10. Removal of 20 causes mentioned above. Other details are given below.

See Rule 41 for overhead protection and Rule 42 for slipping, tripping, cutting, drowning and falling hazards, of Building and other Construction Workers Central Rules, 1998. See their summary in Part 7 of Chapter-28.

Fall Energy:

Energy requires for skull fracture is 30 to 75 fool pound. White and Brown indicated that 18 mph (27 ft sec) is a velocity (of fall or impact) which may kill 50" of all persons against a hard surface. This is equivalent to a free fall of 11 ft. Willie Hammer has given following figures:

Effect on man	Impact Velocity		Equivalent Height of fall
Fracture of	**fps**	**mph**	**inch**
Skull	13.5-22.9	9.5-15.0	37-91
Feet & Ankles	12-13	8-9	25-30
Lumber & Spine	8	6	12

Ability of a human body to sustain effect of fall depends on (1) velocity of an initial impact (2) magnitude of the deceleration and (3) orientation of the body on impact.

The kinetic energy of a body falling on a hard surface can be given by a formula :

$$E = \frac{Wv^2}{2g}$$

where w is the weight in pounds, v is ft/sec, g is gravity constant i.e. 32.2 ft/sec/sec, and E in ft-pound. If E and w are known, falling (fatal) speed (velocity) can be known by the same formula. Deceleration 'd' is given by $d = v^2/2h$ where h is the falling, height or stopping distance.

1.3 Statutory Provisions

Section 32 and 33 of the Factories Act, 1948 provide precautions regarding floors, stairs, means of access, pits, sumps, openings in floor etc. Accordingly all floors, steps, stairs, passages and gangways should be of sound construction, properly maintained and kept free from obstructions and substances likely to cause persons to slip. Steps, stairs, passages, gangways with substantial handrails, fencing and safe means of access to every work place, shall be provided to prevent a fall and ensure safety.

Every fixed vessel, sump, tank, pit or opening in the ground or in the floor whose depth, situation, construction or contents are dangerous should be securely covered or fenced.

Section 36 prescribes details of entering any confined space. Before such entry, the space is to be made free of dangerous fume, gas, vapour or dust. Work permit system should be followed and a suitable breathing apparatus and safety belt to be used by the person.

Section 36A requires a portable electric light up to 24 V and a flameproof lamp for flammable atmosphere.

Dimension of manholes, under rule 64 of the Gujarat Factories Rules are given as circular 41 cm dia or rectangular 41 cm x 31 cm. Rule 68 of Maharashtra Factories Rules gives these, dimensions as : circular shoulder width of the person concerned plus 8 cm in diameter, or rectangular - shoulder width plus 8 cm length and 30 cm width.

Rule 68 describes the ladder quality that it should have hooks or an effective non-skid device.

Rule 68E, GFR, provides for suitable and sufficient ladders, duck ladders or crawling boards and a permit to work system while working on fragile roofs at a height exceeding 3 mt.

Clause 2(0) of Sch-19 on Chemical Works u/r 102, GFR, defines 'confined spacer See Part-2.1 for definition.

Rule 61A of the Tamil Nadu Factories Rules 1950 prescribed safety belt details. It should be of leather straps of more than 5 cm width and a D ring at the back for fastening a rope. The other end of this rope shall be securely tied or hooked to some suitable rigid fixture. A competent person shall examine this belt every six months and certify its suitability. Its register shall be produced before the Inspector on demand.

Schedule 19 and other Schedules u/r 102 of the Gujarat Factories Rules prescribe rules, for working at height and depth.

Chapters VIH, XIV, XV, XVI, XVII and XIX of the Building and Construction Workers Central Rules, 1998 should also be referred for safety provisions to work at height and depth.

See Part 7 of Chapter 28.

1.4 Indian Standards

Some IS are :

Ladders - safety code 3696, dog-step steel 8450, for inland vessel 4647, for ship's use 6176, vertical steel 8172, wooden 1634, 4435, turn table for fire fighting 932, extension for fire fighting 930, hook for fire fighting 929, aluminium for fire brigade 4571, pilot 4383, orchard 8942.

Hazards at workplaces - falling material, fall prevention etc. 13416 (Part I to 5).

Scaffolds - safety code 3696, steel 2750, steel tubular 4014.

Platform - for industrial trucks' 12157, folding and base containers 7341, freight container 6927, 6928, 13288, stability test 7631.

Gangways, aluminium shore- 10558, Gantry cranes, design 3177, for lifting air cargo 12462.

Safety nets (fall arrester) 11057. High Chair, safety requirements 6185, push chair safety requirements 6618, wooden tests 5416, chairs and tables, classroom 4837.

Belt - aircraft safety, lap 10682, belt (safety) and harness 3521. Body protection equipment, selection 8519. Footwear for steel plant 10348, Breathing apparatus 10245, Respirators 8522, 8523, 6194, 8347, life jacket 6685.

Structural - loading standards 875, movement, field monitoring 12023, chain 5616, steel work erection, safely code 7205.

See also Part 3 of Chapter-25 and Part 2.2 of Chapter-15.

1.5 Safety requirement while Working at Height

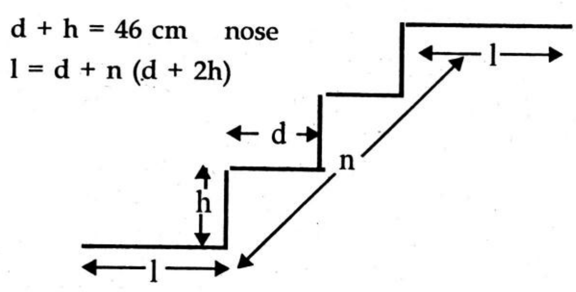
Falls happen due to falling from stairways, runs, ramps, gangways, floors and ladders. Therefore safety aspects of their design, construction and use are explained below:

1.5.1 Stairways:

The slope of a stairway should be 30° to 35° with the horizontal. The tread width should not be less than 24 cm plus a non-slip nosing of 2.5 cm. The riser height should not be more than 20 cm and not less than 12.75 cm and should be constant for each flight. All stairways should be fitted with railings on the open sides and hand rails on sides which are otherwise enclosed. The height of the railings at the stairs should be not less than 75 cm or more than 90 cm measured from the top surface of the stair tread. The stair landings should be protected by railings and toe-boards. Non-skid strips on stair treads can prevent slipping.

Adequate lighting on stairway should be provided to avoid accidents.

Two formulae are quoted in ILO literature.



where d is the depth of the step, h is the height of the riser, n the number of steps and 'I' the length of the landing.

Recommendation for h is 16 to 20 cm, then 'd' should be 30 to 26 cm.

The width of the staircase should be more than 75 cm. Instead of continuous steps, groups of 5 to 6 steps should be preferred. Turning staircases should be avoided. Steps in outdoor staircases should have a slight (1 to 2%) slope towards the nose to run away the water.

Stairways should be of fireproof material to give support for a longer time. Stairwell acts as a chimney. Therefore it should be kept free from smoke and gases. This can be achieved by providing top and bottom ventilation and self-closing fire doors on each landing. Double doors are provided to form an air lock. In high rise building, positive ventilation pressure is applied in case of fire, to drive away smokes.

Proper signs and symbols should be marked in traffic aisles. Arrows for escape routes are necessary.

1.5.2 Ramps, Runways and Gangways :

The slope of ramps, runways, gangways etc. should be as small as possible and the recommended maximum is 15° to the horizontal. Cleats not more than 40 cm apart, should be provided on ramps With steep slopes. Toe-boards should be provided where a ramp extends over a work place or a passage. Wire screens are necessary on the sides, if there is a risk of materials falling through the sides.

Runways are long with uniform slope as they are at arodram.

Chapter- VIII (R.82 to 85) of the Building Workers Central Rules, 1998 are pertaining to runways and ramps.

1.5.3 Floors and Platforms :

The design should consider all types of load in the form of materials, persons and other forces acting on the floor. Acid proof bricks laid in acid resistant plaster should be the choice of flooring for a workroom in which acids are handled. Unprotected floor edges situated at heights and openings, sumps, pits etc., in platforms or floors should be protected by railings, toe-boards or guards. The height of the railings from the base should be not less than 90 cm or more than 120 cm. It should have intermediate members to shorten the gap less than 47 cm. The toe-board should not be less than 15 cm in height.

Floors should be of sufficient strength and shall never be overloaded. They should be non-slippery, free from holes, openings, pinch points, uneven surfaces, irregularities, accumulation of oil, water, waste, dust etc. Near wet processes and water showers, proper drainage should be provided.

Open gutters, kerbs and floor openings (holes, chutes, inspection plates) must be fenced or guarded to protect unwary persons or prevent material falling through it to the floor below.

Non-conductive floor in explosive atmosphere pose special hazard. Discharge of static electricity generates spark which can ignite the explosive mixture near the floor. Therefore steel tipped or nailed boots or dropping of steel tools on such floor is hazardous. Such floors must be earthed properly.

In industry, criteria for floor selection are many. In addition to strength, comfort and cost, resistance to (a) wear and abrasion (b) chemicals (c) fire (d) environmental factors and (e) material in process are also to be considered.

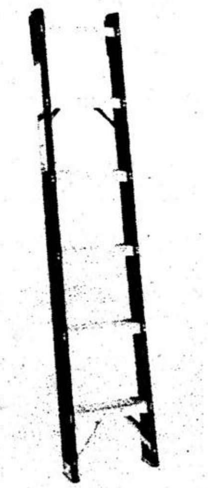
Floors are also of many types. Acids and alkali should be avoided on concrete, granolithic, linoleum, magnesite, quarry tile, ceramic, wood and terazzo type floor. Solvents and oils should be avoided on rubber, thermoplastic, vinyl and vinyl asbestos floor. The cleaning process should not damage the floor affecting its strength or anti-slip properties. Cleaners like soaps, natural detergents, alkaline solution, abrasive powder and damp floor cloths should be used.

Slope is an important factor in floor design. 1 to 2% gradient towards drain helps ensure to flow away water and keep the surface dry.

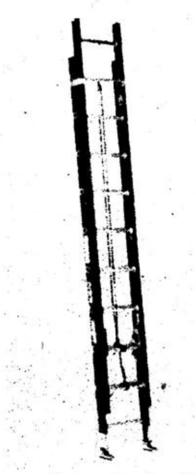
1.5.4 Ladders:

Ladders may be classified under two broad categories, the portable and the fixed. Since the portable ladder is a rather hazardous piece of equipment, every effort should be made, wherever possible, to replace it by fixed stairs, fixed ladder, scaffolding or any other suitable arrangement. Not using ladders where required is a common cause of serious accidents. Men climb on machines, equipment, boxes, barrels, etc., to get access to places above the floor and thus get involved in accidents.

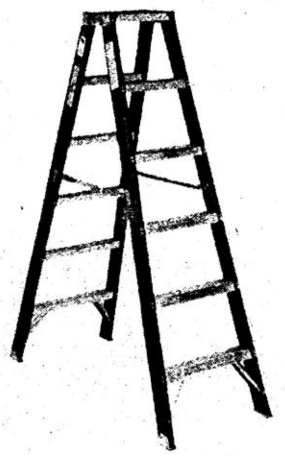
Step Ladder



Shelf Ladder



Extension Ladder



Step Ladder
Entry from either side

Ladders should rest on firm ground and its top should extend at least 1 in above the place of landing.

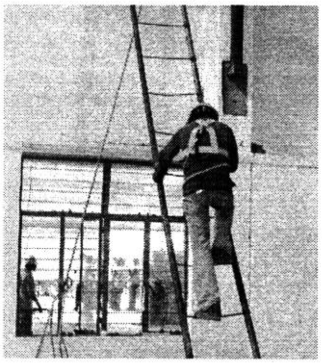
Step (Swing back) ladders and folding trestle ladders : In situations where there is no suitable facility to lean the ladders, such ladder should be the right choice. Step (Swing back) ladders are generally provided with a convenient platform and a hand rail at the top.

Fixed ladders : Wherever the length of a fixed ladder exceeds 9 m, it is necessary to provide a crinoline for ensuring the safety of the user. Alternatively, a. suitable fall arrester should be used. In the fall arrester a slide runs smoothly up and down a steel cable fitted along with the centre of the ladder. The slide is attached to the user's belt by a chain. The slide moves up and down the cable as long as the user climbs or descends at the normal speed. If the user falls, the abrupt pull on the slide causes it to catch on the cable and thus the fall is arrested (controlled).

Transport of ladders : Ladders should be carried always with the leading end at least 2 m above the ground. Long and heavy ladders should be carried by two or more persons. The ladder is safest and easiest to climb when it is at an angle of about 75° to the horizontal, i.e. to a slope of about four vertical to one horizontal.

Portable ladder should not be more than 20 ft long.

Non-slip devices for ladder feet : Slipping of the feet of the ladder can be prevented by fixing non-slip ladder shoes to the stiles. They are of fixed or pivoted type, and the soles may be of rubber, cork, braided rope, leather, felt or lead. Steel spikes or pointed ferrules fixed to the feet of the stile, also serve as ladder shoes. Lashing the ladder by side guys should be resorted to where no anchorage is available near the top. A very long ladder should also be tied by guy ropes as shown in the figure.



Climbing ladders : A person ascending or descending a ladder should always face the ladder. Facing away from the ladder while descending is a dangerous practice. When climbing or descending a ladder, the rungs should be held firmly hand over hand. It is easier and hence safer for a person to cling on to a rung than to a stile, in case the foot slips. However, in the case of fixed ladders with wide Steps and narrow stiles, it is safer to hold the stiles.

Ladder behind door is unsafe condition

Tools should be carried in a holster attached to a belt or in a tool bag or box slung from a strap over the shoulder. The safest procedure is to hoist or lower the tools and materials by a rope. There is greater danger of slipping when the footwear or rungs are wet, dirty or covered with paint, plaster, grease or oil. Therefore they should be cleaned.

Work on ladders : Working from the top of a single ladder can be particularly dangerous when the job requires the use of both hands. The safer way is to stand on a rung about a meter below the top rung to which safety belt is attached. The equilibrium of ladder can be easily upset if one leans sideways.

Misuse of ladder : Use of trestle ladders as single ladders can easily lead to accidents. **Crawling ladders** used over roofs are not designed for use as ordinary single ladders. They should be supported throughout their length. Likewise, single ladders are not designed to be used in a horizontal position as bridges or platforms. A door should be closed before placing ladder over it. Do not use metal ladder near live electric lines. Use the ladder by facing toward it and not otherwise. Ladders should not be put on aisle. Do not rest it on drums, machines, boxes etc. to reach at height. Filling in cracks and .faults or covering up repaired portions with putty and paint is a dangerous practice as the potential weak points are then hidden and cannot be detected during inspections. Ladders should not be allowed to lie in the open exposed to the sun and the weather.

Chapter-XV (R. 172 to 174) of the Building Workers Central Rules, 1998 gives some provisions for ladders.

1.5.5 Scaffolding:

(1) General Requirements:

A scaffold is a temporary structure that provides support for workers, plant and materials used in building, construction, maintenance, repair and demolition work.

The scaffold serves two purposes. One is to provide a convenient platform for persons to work at height and the other is to provide a safe means of access to all places where any person may be required to work at any time. Accidents at scaffolds are generally caused either due to direct collapse of the scaffold or as a result of persons or material falling off the scaffold.

The scaffolds should be of sound material, sufficient strength (4 times the expected load) and properly designed. Their erection, alteration and dismantling should be done under the supervision of a competent person. They should be securely supported or suspended and should be properly strutted or braced to ensure stability. Normal size is 4 cm thick x 23 cm wide x 3-4 m long.

Steel components of tubular (normally 5 cm dia) scaffolds should conform to IS:2750 and 4014 for Steel Scaffoldings. Wood and bamboo should meet the specifications laid down by the Forest Research Institute and College, Dehra Dun.

Overhead protection, not more than 3 m above the work platform of the scaffold becomes necessary if overhead work is going on. Similarly for the persons working or passing under a scaffold, at least 30 cm projected canopy or screen should be provided at the scaffold working level.

In high wind or storm work on scaffold should be avoided. No hot work should be carried out on wooden platform. Fire fighting facility should be kept nearby.

Means of Access : Failure to provide such access has caused serious accidents. The safe means of access may be ladders, portable or fixed, ramps, runways, gangways or stairways. It is recommended that portable ladders should not be used as a means of access where the height of the scaffold platforms exceeds 3.75 m. Slope of the ladder should be 4 vertical to I horizontal. It should rise I m above landing platform and securely fixed at upper end. The use of cross braces or framework of the scaffold as a means of access should not be permitted.

Width of working platforms : The following minimum widths are recommended as a general rule.

1	If the platform is used as a footing only	0.7 m
2	If the platform is used for the deposit of material	0.9 m
3	If the platform is used for support of any higher platform	1.1 m
4	If the platform is one upon which stone or bricks are dressed or roughly shaped	1.3m
5	If the platform is used for support of any higher platform and is one upon which stone or bricks are dressed or roughly shaped	1.5m

Railings and toe-boards : A common cause of accidents at scaffolds is the failure to provide railings at the exposed sides of the scaffold platforms. Often, the failure is when the scaffolding is erected for jobs of short duration. Where materials are stacked on a platform, the height of the toe-board may have to be raised; or it may even be necessary to cover the entire space between the top rail and the toe-board with wire netting or planks. Normal height of railing is I m and toe board 15 cm. '

Boards and planks in working platforms, gangways and ramps : For platforms of wooden planks, in general, the spacing should not exceed the following:

Planks 32 mm thick	1.0m
Planks 38 mm thick	1.5m
Planks 50 mm thick	2.6m

Boards or planks which form part of a working platform, gangway or ramp should not project beyond their end supports to a distance exceeding four times the thickness of the board or plank. 50 mm projection is desirable. Overlapping of boards is unsafe.

Hazards and Safety measures: Scaffolds should never be loaded in excess of the working load for which they are designed. Wood scaffolds are not generally painted. However, in case of ladders and certain permanent types of scaffolds such as the mobile scaffold, protection is generally provided by periodically treating them with a coating of linseed oil.

Main hazards with scaffolding are:

1. Unsuitable or faulty material of construction.
2. Inadequately supported scaffold boards.
3. Improper platform width and thickness.
4. Non-securing or bracing scaffold to the structure. Damaged or wrong couplers.
5. Unsecured ladders slipping.
6. Omission of guard rails or toeboards.
7. Overloading the scaffold.
8. Erected on uneven ground.

Scaffold foundation should be verified before erection. Loose or friable packing like bricks should not be used as support. For height more than 15 mt, steel scaffold should be preferred and not a wooden one.

Inspection' after 7 days and after every damage is necessary. Points to be checked include : stability, ties and fixing, alignment of members, bending, tightness of lashing (3r couplers, planks, platforms, guard rails, toe boards and condition of ladders.

Warning notice should be displayed near incomplete or damaged scaffold.

Dismantling should be carried out in the reversed order to erection. Materials should not be thrown from heights and should not be left lying here and there. They should be properly collected.

After completion of work, all scaffold materials should be stored in a dry protected place using racks, boxes or trays. The damaged parts should be replaced or repaired, cleaned, treated with preservative or paint. Couplers and other fittings should be lubricated.

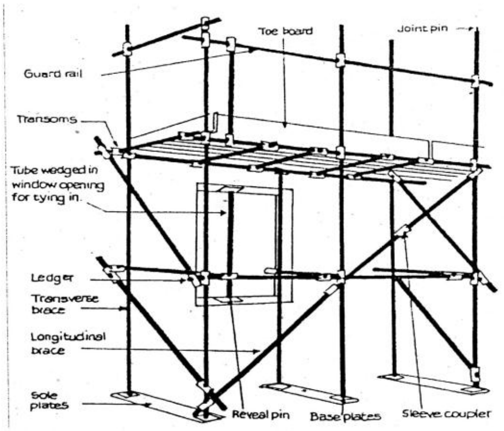
Chapter-XIX (R.188 to 205) of the Building and Construction Workers Central Rules, 1998 gives provisions regarding scaffold.

(2) Types of Scaffold :

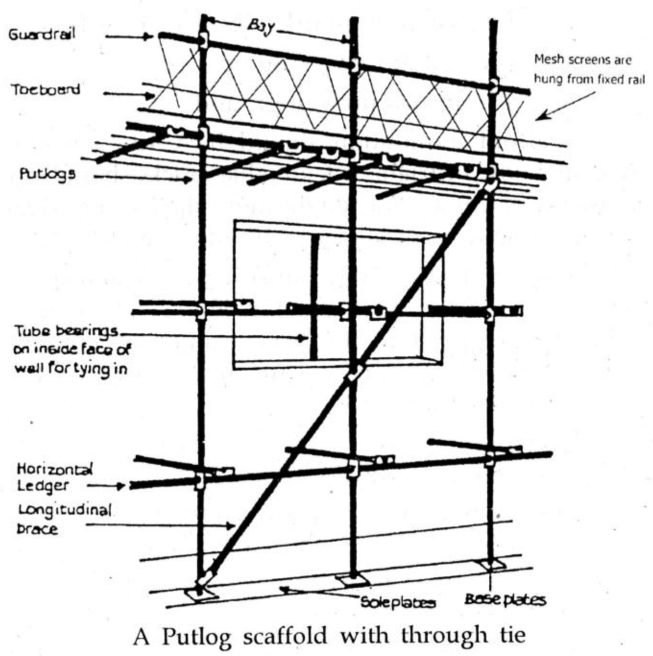
Some common types of scaffold are as follows :

1 Pole type scaffolds :

It may be an independent structure or the putlog type erected and supported near wall or another structure.



Independent tied scaffold with a reveal tie



A Putlog scaffold with through tie

The uprights (vertical poles) should rest on strong foundation to support load without settlement. They should not be kept more than 3 mt apart. Tubular uprights have steel base plates placed on wooden sole plates. Soft ground should be well rammed and levelled.

Fixings like steel bolts, nails or fibre rope of approved size, joint pins and couplers should be properly fitted. For load bearing right-angled or swivel couplers should be used. Putlog couplers are useful for putlog members only. Putlog members (horizontal) should at least 10 cm be inserted in wall. Bracing (diagonal connection) should be tied to ensure structural stability and prevent buckling. To prevent overturning the scaffold should be secured at intervals not greater than 7.6 m vertically and horizontally.

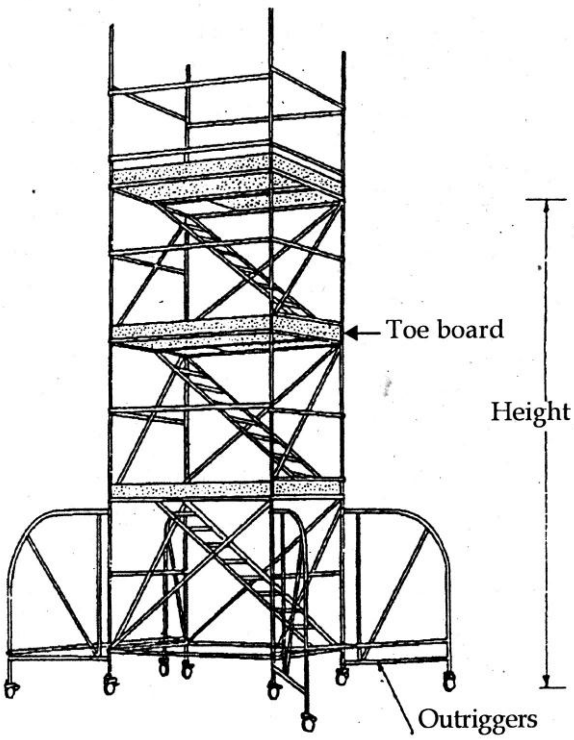
2 Rolling Scaffolds or Mobile Towers :

Such scaffolds move on rollers (wheels) or castors with wheel locking device. They are portable and most useful for maintenance work.

To prevent overturning, height should not be more than three times the minimum width of the base. Minimum base length should be 4 ft. While pushing or pulling the tower, persons should not ride on it. Tools and materials should be removed before moving.

The top working platform must have handrails and toe boards. It should support 30 lb/ft distributed load. Rigidity of the tower is secured by diagonal bracing on all four sides and on plan.

Moving the tower by pulling at the top or leaning sideways should be avoided.



Rolling or mobile tower scaffold

Rolling or mobile tower scaffold is shown below.

3 Outriggers

Rolling or mobile tower scaffold Outrigger Scaffolds:

It is a balcony type cantilever scaffold resting on wall. If other types of scaffold are possible, this type should not be used.

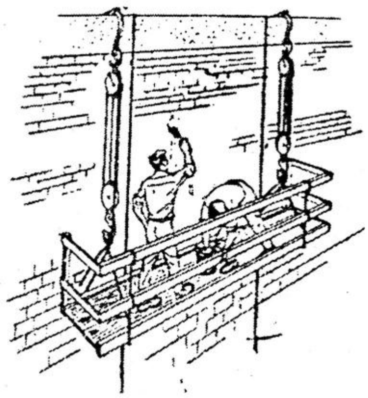
The outriggers should be passed right trough the wall and be secured on the inner side. Supporting hook between brick joints is dangerous.

Platform should not project beyond 2 mt from the wall. Guard rail and toe board should be provided.

4 Swinging (Hanging) Scaffolds :

Here the platform is hanging by two chain pulley blokes, ropes and hooks on supporting beam. Suspended platform can be raised or lowered as per need. Movement of both the ends should be simultaneously. The anchorage and the suspension gear should be strong enough to withstand the load with good factor of safety. Suspension ropes should withstand 6 times the intended load. Rope diameter shall be more than 0.75 inch.

A safely rope shall be provided in addition to .the suspension ropes.



Hanging scaffold

The width of the platform should be more than 50 cm and less than 90 cm. Guard rails and toe boards necessary, on all the three sides open. The platform should be lashed or secured while in use, to prevent swaying.

Each person working on swinging scaffold should wear safety belt with lifeline attached to an anchorage other than the scaffold itself.

5 Suspended Scaffolds:

Two or more platforms are suspended by ropes from overhead outriggers anchored to the building.

Such scaffolds are designed with a factor of safety 4 and shall never be overloaded. Anchor plates should be tied with U bolts. Counter weights are used to prevent overturning. Wire ropes (FS 6) are used to support scaffold. Hoisting drum (like winch) is used with at least 2 dead turns. Gap between handrail and toe board should be covered by a wire mesh of 38 mm and 16 gauge wire. Overhead protection should be provided if risk of falling objects is possible.

6 Boatswain's Chair:

Boatswain's chair is used for supporting and hoisting single person in sitting position. General chair (seat) size is 60 cm x 30 cm, with 25 mm thick timber. Cleats extending in front to at least 23 cm should be securely fixed under the chair at both ends. The chair is supported by a suitable sling passing through the four corner holes in the chair for proper stability. The suspension rope is fixed to an overhead support or passed through a pulley block fastened to such support. The free end is secured to a conveniently accessible anchorage and the person in chair must wear a safety belt, the life line of which is secured to the tackle supporting the chair. Fibre rope slings should not be used if the person in the chair has to do welding or cutting work.

1.5.6 Safety Belts and Harness :

In addition to all engineering controls and work permits, personal protective equipment should not be forgotten while working at height or depth.

Safety belts of various types are available. Pole safety belt, general purpose safety belt with or without remote anchorage and harness (man hoisting by another man) type safety belt are in common use. They should fulfil IS specifications stated in foregoing Part 1.3. They are available in leather and webbing of natural and man made fibres, of which, webbing is superior to leather. Webbing can withstand loads 3 to 4 times that of leather of the same size. Web material maybe cotton, nylon or dacron. While selecting a belt, its normal and emergency use should be considered. Life Lines of manila rope of 19 mm diameter or nylon rope of 13 mm diameter are suitable provided a shock absorbing device is available. Care of belts is always necessary.

Respiratory equipment should be selected depending upon the working environment.

Harness consists of a safety belt and rope or lifeline. It can stop a person falling or he can be pulled out if working below in a confined space.

(1) General Requirements:

All workers working at height of more than 2 m (window cleaners, construction workers etc.) must wear safety harnesses i.e. safety belts connected with ropes. The belt should be tied with the body while the free end of the rope should be anchored with a fixed unbreakable sound structure or should be held by another person standing outside a confined space when the wearer is working inside. The belt and rope should be of sound material, examined by a competent person every six month and maintained in very good condition.

Length of the rope is normally 2 ill since more fall height and sudden arrest may cause internal injuries to the workers.

But in case of working in depth the rope length should be more than 2 m and extending up to the bottom level of working since the worker is to be pulled out when he gives indication of any difficulty to him or when it is observed by the person holding the rope, standing outside and watching the person working inside.

Workers should be trained, encouraged and supervised to wear safety belt properly because it can save their precious lives.

All safety equipment are to be freely supplied by the employer and it should be seen that workers use them. This is a statutory requirement.

Safety belts are required for workers working on towers, masts, windows and building projects and also in confined spaces like tanks, boilers, gutters etc. Car and aeroplane occupants also need safety belts to be protected from crashing and overturning.

Free end of the rope shall never be anchored on a structural member being placed or any loose or weakened structure. Supervisor and the worker must ensure this. Wrapping of free end (rope) on waist is a wrong practice. Increasing length of the rope without permission can also lead to hazard. Anchorage point should be at such height so that there shall be minimum slackness in the line. It shall never be lower than the belt attachment to the restraining line.

Safety block (like chain pulley block or hoisting drum block) is used to connect the wire rope with the safety belt to allow more freedom of movement. A sudden pull operates lock or brake to stop the rope. Because of a friction brake on the rope drum, jolt is avoided and the falling person is stopped smoothly. In another design, a centrifugal brake is applied on the drum so that the person descends slowly to reach the ground.

Tensile tests and drop tests are carried out on safety belts and apparatus used with them.

Safety belts should be kept in a cool, dry and well ventilated place. Regular cleaning, visual inspection for defects and repair only by a competent person are necessary for good maintenance.

See Part 5.6 of Chapter-25 for further details of fall protection.

See Chapter-XVI (R.175 to 180) of Building and other Construction Workers (Central) Rules, 1998 for catch platforms, safety belts, nets etc.

(2) Types of Safely Belts:

Mainly four types of safety belts are .in practice:

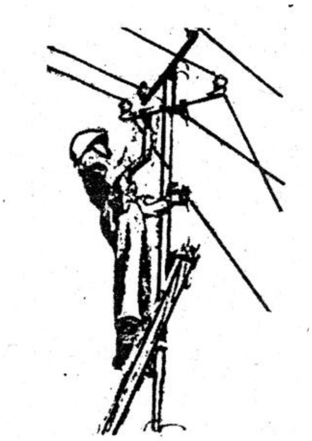
1 General purpose Safety Belt :

A Full Safety harness with fall arrest block

It consists of a waist belt, a restraining line (lifeline) and the metal components. Straps covering shoulders, chest, waist and hips are preferable as by wearing it the forces during fall will be absorbed not only by the trunk but also by the legs. Choice of model depends on working method, time of work, environmental factors etc. Rope (normally 2 m) is attached to D ring secured to the waist belt.

For window cleaning, straps are long enough to fit windows and terminate in snap hooks for anchor on each side of the window. Two restraining lines are used for window cleaner's belt.

2 Lineman's or Pole Safety Belt :



To climb on poles, towers, masts, trees etc. these belts are used. They are used as support while climbing and protection while falling. Here waist belt is fitted with 2 D-rings at different points. The length of the restraining line is adjustable by a buckle. Generally fall is restricted to 60 cm

3 Harness (Man hoisting) Safety Belt :

It is used for working in a confined space, silo, tank, vessel etc. The life line is held by a person standing outside to rescue the wearer when he is unable to come out by his own efforts. On the rescue line there is a wrist strap by which the wearer can be hauled up through a manhole or other opening.

Work permit should be followed and the workplace should be made free from any toxic/flammable vapour and oxygen deficiency. See Part 1.8 of Chapter-19 for more details.

1.5.7 Fall Arrestor or Anti fall Device :

Fall arrest or antifall device

Here waist belt is connected to a sliding anti fall device which automatically stops while moving in fall direction. Here fall arrest distance is small due to close (short) life line.

Anti fall systems are of two types (1) With a sliding and blocking device on a vertical safety support (pole, cable rail) (2) With an automatic catching device for rolling, unrolling and blocking a tether (cable, rope, strap). Specific braking system includes an absorber of kinetic energy used with a tether (for details see Reference No. 5 at the end of this Chapter).

A competent person should be consulted for selection of appropriate device. A cross belt is tied with the body and a sliding mechanism moves with the bjody in upward direction but it will be

locked and stop the fall at the descending movement. Other type allows the horizontal (to and fro) movement but will catch the falling body through rope and a shock absorber.

1.5.8 Safety Nets .

Where safety belt is not possible or in addition to safety belt for further safety of a person, particularly when fall height is very high or falling in sea or deep water is possible, or work surface is fragile and sudden fall is possible, safety net is very much essential to catch a falling person. Net is useful to stop a fall of a person as well as of falling objects. For stopping falling material, the mesh size should be small.

The net and the structure to which it is attached should be capable of catching and supporting at least two persons at a time.

The nets are made of synthetic fibres which are strong, light weight and weatherproof. Diameter of the mesh cords and that of the border cord should be at least 3 mm and 8 mm respectively.

Standard net size is 6 x 4 m but it can be manufactured of required sizes also. The mesh size of 5 x 5 cm is preferable. For falling objects that size should be 3x3 cm.

Four corners should have eyes to support. Big net should have eyes every 2 m on the boarder cords. Two nets can be connected with each other to cover more surfaces.

While attaching net with the structure, some safety distance should be maintained. It should not be lower than 3.5 m below the working level and less than 3.5 m above any object or structure below the net. The net must project at least 2 mt outside the falling area.

Nets should be cleaned regularly and checked periodically for cuts and other objects. It should have serial number so as to keep record of maintenance.

Nets should be kept on pallets in a dry, cool and well ventilated place. It should be kept away from chemicals and hot materials.

1.5.9 Working on Roofs :

Serious accidents happen due to fall of persons working on roofs. Fall through fragile roof sheeting, loss of balance due to the slope of the roof or effect of wind and insufficient care while working at the edge of the roof constitute the principal causes of such accidents which could be prevented by appropriate safety measures like crawling or walk-boards, railing, safety belt and safety net.

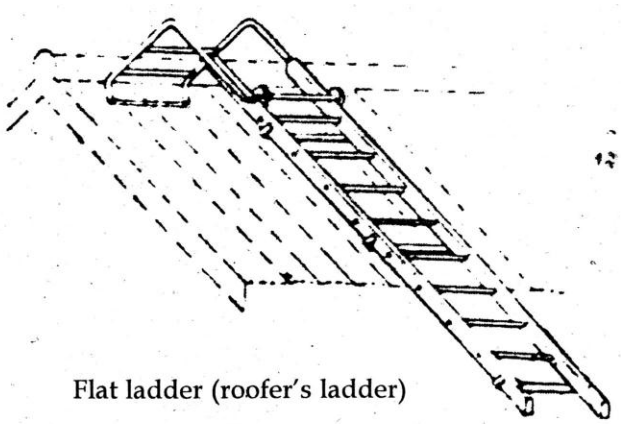
Use of a safety belt alone' while working on a fragile roof or at a height more than 6 ft (2m) is not permitted. It is dangerous and many fatal accidents have happened because of this condition. Sound platform, adequate support or safety net should also be provided.

See Part 5.6· of Chapter-25 for more details of fall protection.

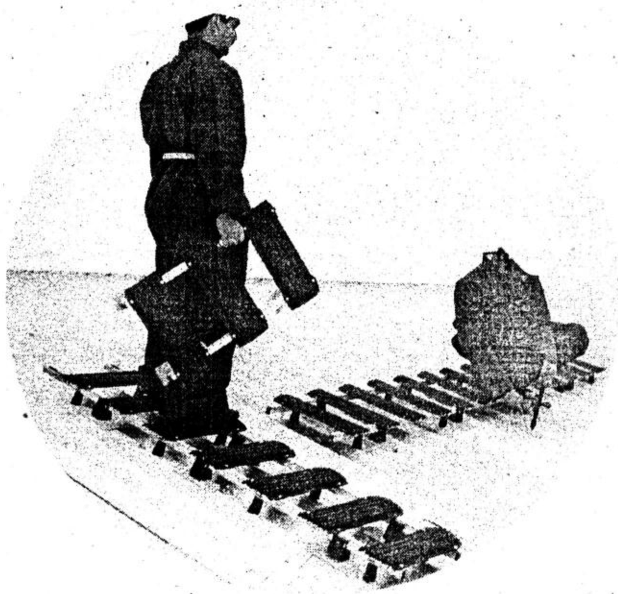
Factors affecting fall of roofers are working height, nature, shape and slope of the roof, roof covering material, roof condition and the weather.

Low-strength roofing materials are asbestos, cement, glass, plastic, wood and roofing tiles. Heat, rain, humidity, pollution and corrosion spoil the roof condition. Hidden cracks in a roof increase the hazard.

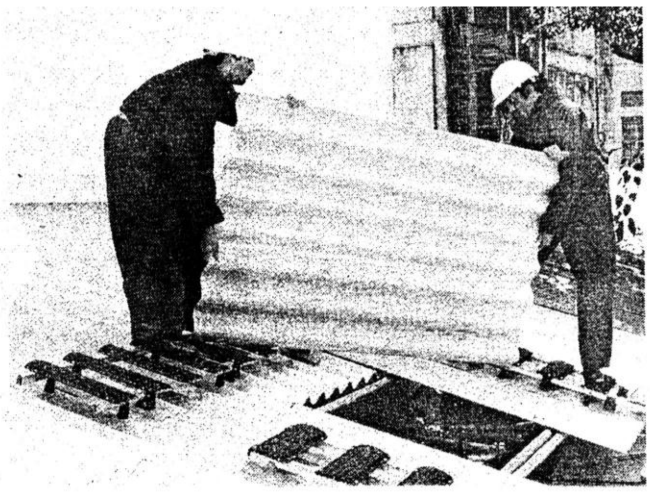
The shape of the roof-flat or sloping with a straight, polygonal or curved profile - affects the fall direction. Water, oil, snow, moisture, chemical, dust and other deposits on roof surface increase fall proneness. High wind and bigger sized sheet in hands cause a roofer to lose his balance.



Flat ladder (roofer's ladder)



Cat ladder or crawling board



Whatever may be the reason, danger of falling toward thereof edge or falling through the roof opening is always there. Smoke or gas coming on the roof or overhead electric power lines also contributes hazards.

Roof work should be pre-planned and only fit and skilled workers should be employed.

Assessment of the nature of work and possible hazards will help to draw safety work permit. Fixed or mobile scaffold, flat ladders (roofer's ladder), sufficient cat ladders or crawling boards side by side, safety belts and safety nets must be provided to each roofer. Anchor points, anchor hooks, bars, wire ropes or other fixing device should be decided. This arrangement must be made first and then only the work may be started under strict supervision. Even for a short duration work, such safety precautions should not be avoided.

Measures should also be taken to protect persons below. Safety cordon, warning notice and fall arrester net can help in this regard. Fall arrester net should be firmly tied as near as possible under the roof to minimise the fall distance.

The workers should be trained for work at heights. Their medical examination is also useful. All walk boards and equipment should be sufficient in number.

Falls through fragile roofing materials : The common, practice of walking along the purling cannot be relied upon. The best way to prevent falls through such fragile materials is to use cat or roof ladders. They should be at least 38 cm wide and should have cross battens at least 3.2 cm thick, fixed not more than 38 cm apart. Safety belts and fall arrester net should also be used as an additional precaution. A permit-to-work system under the control of a responsible person can help to ensure .that the workers are not allowed to work on roofs without taking appropriate safety measures. Rule 68E of the Gujarat Factories Rules requires this provision.

Reinforced AC Sheets are now available in the market. -They are not as fragile as normal AC sheets. The manufacturer 'Eternit Everest Ltd.', New Delhi, names their product as "Everest Lifeguard" and tells it a solution for* 'Safety on Roof Tops". Their literature runs as under:

Everest Lifeguard a high strength fibre cement sheet, with Polypropylene reinforcement strips inserted along precisely engineered locations which run the full length of the sheet in each corrugation, thus providing maximum reinforcement strength with no loss of durability in service.

This product has been developed in conformance of the guidelines issued by UK's Health & Safety Executive, with regard to Health & Safety on roof work (HSG33).

Falls from sides of roof : In case of flat roofs, either the standard railings and toe-boards or a complete barrier to a minimum height of 90 cm should be provided. For sloping roofs, the barrier may be in the form of scaffold boards extending to a minimum height of 40 cm above the roof surface and a guard rail at a height more than 90 cm but not more than 120 cm.

See Chapter-XIV (R.169 to 171) of the Building and other Construction Workers (Central) Rules, 1998 for steep roof.

1.5.10 Safety Work Permit :

A well designed 'Permit to Work System' is always useful to check safety points before hand. Formats used by some good companies are reproduced below:

Format 1 : Safety Work Permit for Working at Height Permit No Date:

Name of the Company	
Plant & Location	
Elevation / Height	

Job Description	
Validity period	

Please answer the following after checking at site. If answer is ‘No’, justify with your remarks :			
Sr.	Check Points	Yes/ No	Remarks, if any
1.	Whethre the job requires erection of scaffolding for making a temporary work platform at high elevation ?		
2.	A standard scaffolding has been erected to make a temporary work platform at required height ?		
3.	Proper ladder has been provided for access to and egress from the work lace at height ?		
4.	Work platforms are provided with hand rails ?		
5.	Static lines provided for hand hold to facilitate safe movement of workers ?		
6.	Safety net (s) provided (Where erection of scaffold or work platform is not feasible or otherwise risk is high) ?		
7.	Proper use of safety belt by all workmen is ensured ? The safety belts are of standard make and inspected ?		
8.	Use of safety helmet and safety shoes by all workmen is ensured ?		
9.	Crawling boards / duck ladders are used for work over slopping roof / fragile roof ?		
10.	Area below has been cordoned off ?		

Issuing Authority (Engineer-in-charge)	Permittee (Site Supervisor)
Signature of the Site Engineer Name ____________________ Company ____________________ Date ____________________	Signature of the Site Supervisor Name ____________________ Company ____________________ Date ____________________
Work completed and this permit expired (Date & Time) :	

Format 2 : Safety Work Permit to work at Height or for Digging

Name & Address of the Company :						
	Work Permit to work at Height or Digging				**Permit**	
					Number	**Date**
Date and Time of Working		Validity of Permit		Location of Work	Initiating Dept.	
From	To	From	To			
Details of Work to be carried out						
General declaration by contactor’s supervisor who will be available at site.						

I hereby declare that the work detailed above will be carried out strictly as per safety precautions (Instructions A or B) mentioned overleaf. I ensure that only those persons who are instructed by me about the safety precautions to be observed and who are trained in such work will do the said work.

I will be available at site throughout the period of work.

_______________	_________________________
Date	Signature of Contractor & Name

Contractor :

Please read carefully and follow instructions (A or B) mentioned overleaf.

Permission Granted for (Tick ✓) :

☐ Working on Fragile Roof / Working at Height **(Refer Instruction A)**
☐ Digging work **(Refer Instruction B)**

Issuing Department		**Receiving Department**	
Name :		Name :	
Signature :		Signature :	
Work completed and this permit expired (Date & Time) :			

Copy distribution : 1st Copy – Issuing Dept., 2nd Copy – Safety Dept. 3rd Copy – User Dept., 4th Copy - Contractor

Instructions A : Permit for Working on Fragile Roof like AC Sheet Roof/Working at Height:

Conditions for Issuing the Work Permit:

1. No person shall be allowed to work on any fragile roof (like AC Sheet Roof) at any height without this permit.
2. The permit is generally valid for the period mentioned 'on the permit and can be extended; but the same permit can be re-authorised by Safety Department.
3. When .the work is on progress, the valid permit must be available with the supervisor who must be available at work.
4. Any authorised person from concerned department or Safety Department will have the authority to stop the work immediately in case he finds that the work is being 'carried out without observing the safety precautions as mentioned below.
5. The permit is NOT VALID if not authorised by the Safety Department and the declaration is not signed by contractor's supervisor who will be at site.
6. Safety department can revoke, cancel or renew this permit with valid reasons.

Safety Precautions to be followed:

Following safety precautions will be followed by the contractor and his workmen before, during and after the work on AC sheet roof/at height. No person should be allowed to work on fragile roof/at height unless the following conditions are fulfilled.

1. Suitable and sufficient access ladders, duck ladders, cat ladders, crawling boards etc. shall be used and they should be securely fixed or supported. Such working aids are to be inspected by executing department prior to usage.
2. For high risk (more height) fall arrester net shall be firmly tied as near as possible underneath the roof or plane of working.
3. Nobody shall be allowed to go on the AC roof without a valid permit and according to conditions mentioned therein, with the Site Supervisor.
4. Safety belts in good condition and approved by safety department should be given to the concerned persons and they should be trained and supervised to wear them and fasten them securely and correctly with a fixed immovable structure.
5. No worker shall be allowed to step directly on any part of AC sheet roof.
6. No tools/materials shall be left on the roof after each day's work is over.
7. Electrical power supply, if it concerns place of work, shall be isolated.

Instructions B : Permit for Digging work:

Following Safety precautions will be followed by the contractor and his workmen before, during and after the work of digging. No person shall be allowed digging work unless the following conditions are fulfilled.

1. Nobody shall be allowed to undertake any digging work without this Valid Permit, available with the Site Supervisor, who will produce it on demand. -
2. Contractor shall instruct his workers to work strictly as per safety instructions given herein and care shall be taken to ensure no damage to electrical cables and piping underground.
3. Isolation of electric supply, water/oil/gas supply's per the direction of concerned department shall be carried out.
4. Permission of Electrical Maintenance and other concerned 'Department must be obtained before undertaking any digging work.
5. Fencing and Indicators shall be placed around the trench and red lanterns shall also be placed at night, if necessary.
6. Loose excavated material shall be remove< by pei son using rubber gloves.
7. No tools shall be left after each day's wor is over.
8. The Supervisor must be available at sit during the period of work.

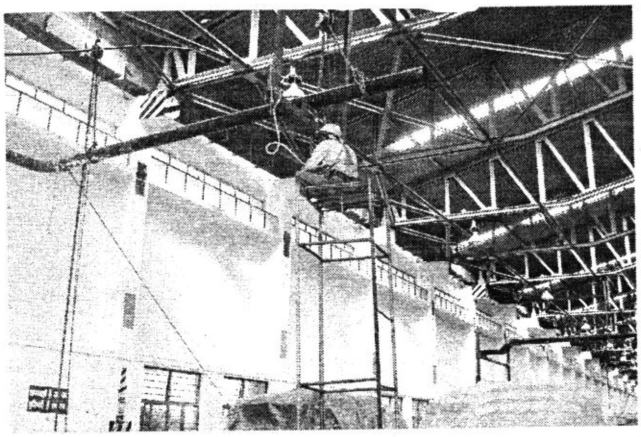
1.5.11 General Precautions while Working at Height

They are as under -

1. Cut off power in nearby electric lines to avoid shock and fall.
2. Do not lift or carry excessive load so as to loose balance and fall.
3. Tools should be attached by lanyard to the belt or garment to prevent their fall on others.
4. Safety helmet, shoes, safety belt, respirator and other PPE should be worn as per need.
5. Keep the work floor always dry, clean and well protected. The floor should be checked for fragility, crack and its soundness to carry load. Non fragile metal sheets or reinforced AC sheets are preferable.
6. Know safe means of access, emergency staircase, fire extinguisher, first aid box and other device like aerial platform, rope ladder etc. before starting the work.

7. Pre-employment and periodic medical examination of workers to check their suitability for working at height. Workers suffering from balance disorders, vertigo, epilepsy, blackouts etc. should not be employed or continued to work at height.
8. Trained Workers: Safety belts, harnesses and lanyards are to be used in conjunction with permanent anchorage points. Workers should be trained to know how to check, wear and adjust before they start work and how to connect themselves to the structure or safety line.

Workers can also use mobile access equipment i.e. mobile elevating work platforms, cradles and mast platforms. All users of such equipment should be trained and competent to operate it. They should also be aware of emergency and evacuation procedures so that if, for example, the power to platform fails, they know what they should do.



It is essential for employers to implement safe working procedures for working at heights.

2 WORKING IN A CONFINED SPACE

Work in vessels and tanks below ground in pits, cellars and basements or inside confined spaces such as silos, tanks, vats, vessels, boilers gutter etc., pose danger and always require permit to work system.

2.1 Meaning and Hazards of Confined Space :

Clause 2(0), Sch-19, rule 102, GFR, defines 'confined space' as any space by reason of its construction as well as in relation to the nature of the work carried therein and where hazards to the persons entering into working inside exist or are likely to develop during working.

Confined Space is also described as a place which

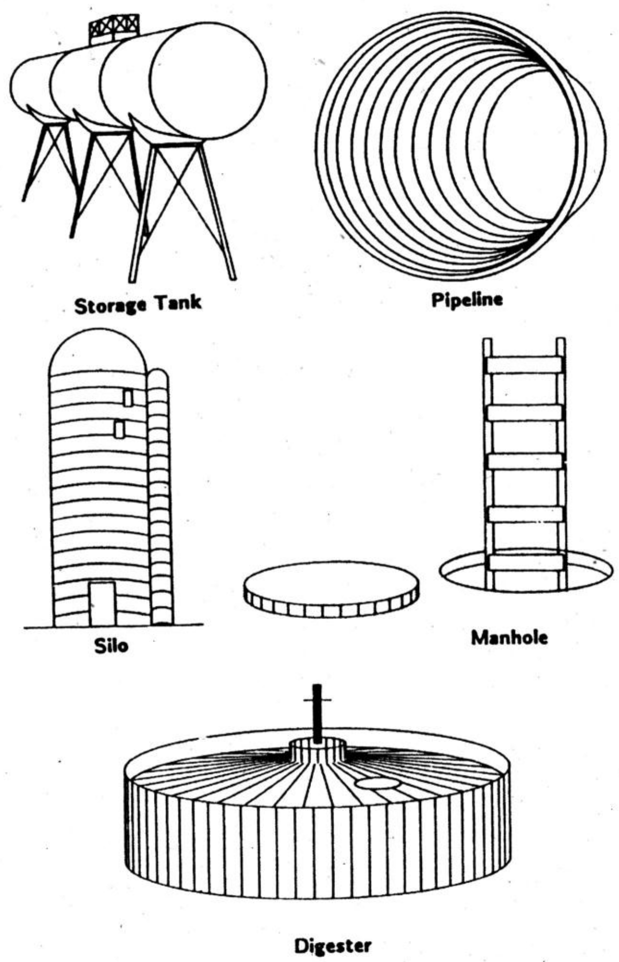
1. Is mostly enclosed and partially open.
2. Is at atmospheric pressure and temperature.
3. Has limited or restricted openings for entry and exit.
4. Is not designed or intended for normal place of work (i.e. not for long time worker occupancy).
5. Has unfavourable natural ventilation due to stagnant air, no free air movement, oxygen deficiency or enrichment or nitrogen atmosphere.
6. Has contaminated air with toxic or / and flammable gas, dust etc and
7. May cause engulfment (swallowing) in unstable or loose material.

Examples (Types) of confined spaces are -

1. Storage tank
2. Process vessels / Reaction Vessel

3. Pressure Vessels
4. Boilers
5. Tank cars (trucks)
6. Tank wagons
7. Digester
8. Wells / bores
9. Under floor/ Floor opening
10. Sumps
11. Pits
12. Silos
13. Pipes
14. Ducts
15. Gutters
16. Tunnels
17. Sewers
18. Vats
19. Bilges
20. Shafts
21. Go-down of grain, sulphur, cement, clay and similarly loose material
22. Roof voids / Gap between roof and false ceiling.

See also Part 3.13 of Chapter 2



Examples of Confined Spaces

Hazards of Confined Space can be classified as-

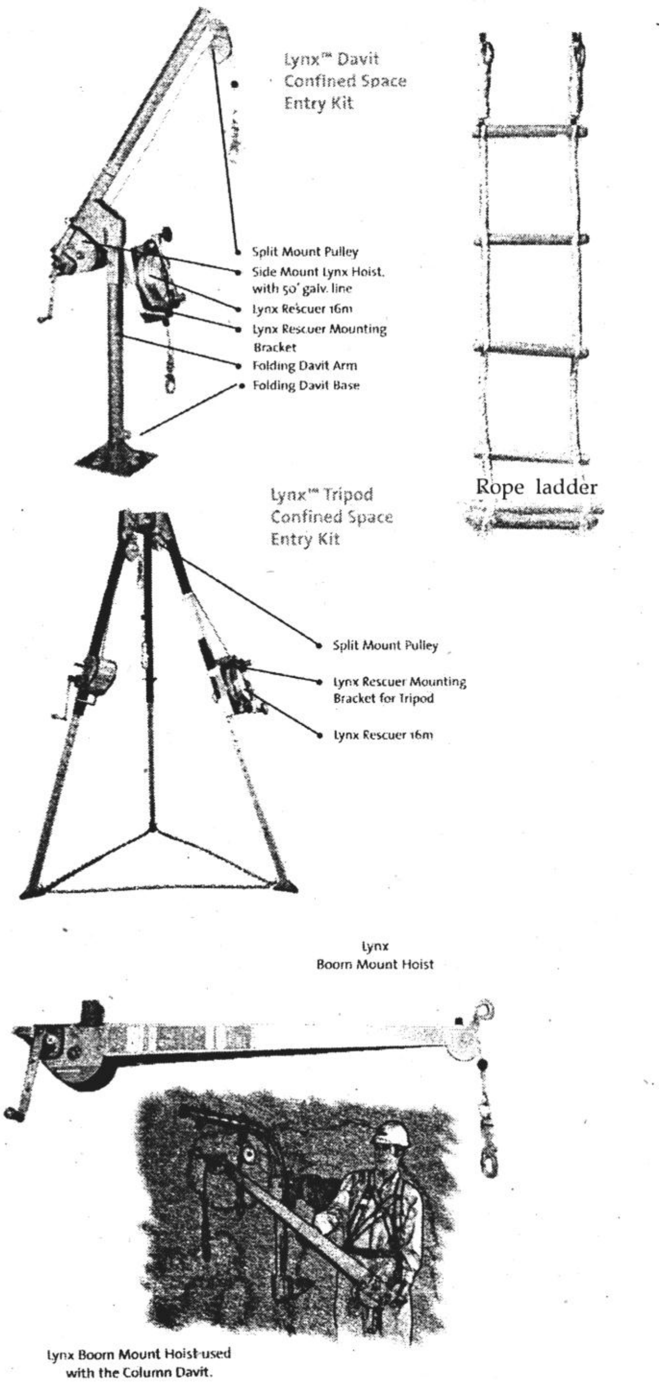
1. Poor lighting and ventilation.
2. Oxygen deficiency.
3. Contamination of toxic and/or flammable gases.
4. Unexpected activation of machinery or flow.
5. No way or no time available for exit.
6. Engulfment (burying) in loose material.
7. Non specific work practices.

Other hazards are suffocation, burning, poisoning, explosion, drowning, freezing, crushing, entrapment, scalding, stroke, heat stress, radiation, physical trauma, injury by moving machinery, slipping or falling etc.

Many fatal and serious accidents have occurred while working in a confined space. Three reasons flammable air mixture, toxic gases and oxygen deficiency - are found responsible for such accidents. Tanks (vessels) with top cover open but all other sides closed, should be considered as a confined space, because, in such situation persons working inside have to face direct fire, explosion, or toxic exposure and have no other way to run away except the only way of their entry. Therefore doubtlessly and as per above statutory definition, such situation/condition is a confined space. One worker died due to solvent fire, one died due to chloroform vapour and two died due to nitrogen (oxygen deficiency) atmosphere in such confined spaces.

Safety equipment for working in a confined space.

Following equipment are useful for working safely in a confined space.



Safety equipment useful for working in a confined space

2.2 Vessel Entry Permit :

Tanks, vats, pits, sumps, vessels, floor opening etc. should be protected by guard rails or cover. Fixed ladder with handrail if possible, should be provided to step down safely. Portable (rope) ladder may be used while working inside a tank or vessel for temporary work.

Statutory provisions for confined space entry are already stated in foregoing Part 1.3 of this Chapter. Other precautions are:

1. Check the concentration of toxic or flammable gas, dust, vapour etc., by a gas detector. Oxygen content should also be checked for safe proportion. It should be >18%.

2. Air line or self contained breathing apparatus and safety belt are essential.
3. Sump pumps with flameproof electric or pneumatic motors and air extraction fans (spark proof) and exhaust ducting to remove heavy vapours are necessary.
4. Complete isolation of the vessel, cleaning, purging and ventilation of the vessel, inspection and testing, safety permit and all rescue arrangements must be done before such work and only a trained worker will work under constant help and supervision.
5. Latest safety and rescue systems should be used. Winch arrangement connected with the worker's harness is useful to lower and pull out quickly. Handfree communication system is available to keep the worker in the tank in constant touch with the supervisor outside. Hand operated clutch, cord and chair assembly can be used to lower the person while working at height or depth.
6. Bottom drain valve and other nozzles should be kept open to allow good ventilation and fresh air in a vessel or tank

Refer Part 16.2 of Chapter-18 for more details of safe entry into a vessel.

Before allowing vessel (confined space) entry permit, it is necessary to carry out hazard assessment of the space. Therefore two types of formats are giver below for use. Necessary changes as per specific requirement should be incorporated.

Format I - Confined Space Hazard Assessment

Plant No.		Description	
Access/ Egress		Ladder State	Scafold Other.
Access Security	Padlocked None	Key locked Other	Simple latch
Impediments to access/ conduct of wok		Plant layout Manual handling None	Dimensions Ergonomics aspects Other
Hazards			
Potential Hazards (if yes, must be monitored)	Oxygen levels Explosive atmospheres	Carbon monoxide Other	Hydrogen sulphide
Cleaning in confined space		Chemical High pressure water None.	Steam Water Other
Hazardous substances stored ? Yes No. (if yes, list names and indicate need for monitoring.		Substance Name	Monitor ?
Illumination		Acceptable	Additional illumination required
Ventilation		Acceptable	Additional ventilation required.
Temperature extremes	Hot	Cold	None
Lockout tag out required Yes No (if yes, indicate energy sources)	Electrical Natural gas Steam Stored energy	Hydraulic Pneumatic Water Static	

Control Measures			
Personal protective equipment required (if hazardous substances present check MSDS for additional requirements)	Escape unit Lanyard retraceable Gloves-type Eye protection – type Hearing protection-type Respiratory protection-type	Industrial clothing –type Communication equipment- type Lighting-type Hard hat Harness	Safety boots Safety line
Persons in confined space	Maximum		Minimum
Emergency response procedures			
Emergency response equipment required.			
Assessor signature		Assessment data	
Manager responsible for confined space		Date	
Copies distributed to		Comments	

Format 2 – Confined Space (Vessel) Entry Permit

Plant No.		Description	
Reason for entry		Inspection Maintenance	Cleaning Other
Details			
Requested by			Date
Control measures.			
Hazard Assessment Number.		Assessment Date.	
Lockout tagout required. Yes. No. (if yes, Lockout permit must be attached).		Hot work required ? Yes. No. (if yes, Hot work permit must be attached).	
Oxygen levels % (must be 19.5 – 23.5%)		Flammable gases % LEL (must be <5% LEL).	
Other gases …………… ppm …………… ppm		Other atmospheric contaminants.	
Personal Protective Equipment At risk assessment. Changes.		Provide details of and reasons for changes to PPE requirement here.	
All persons entering space and stand by persons have been trained.		Yes	No
All persons entering space and stand by persons know emergency procedures ?		Yes	No
Stand by persons			

Issue of Permit to Work (Authorization to enter)

I have reviewed the risk assessment for this space and understand the hazards and control measures required. This confined space is safe for entry to do the work described above provided all precautions are fully observed and that isolation points have been checked and secured.

Approval signature	Date.	Time
This permit to work is valid until (give date and time)		

Persons entering confined space

I have been instructed on the control measures to be observed and fully understand the precautions to be observed and will observe them while in the confined space.			
Name	Date	Time	Signature

Persons leaving confined space

Name	Date	Time	Signature

Withdrawal of Permit to work

All persons and equipment accounted for	Yes	No
Equipment checked and restored correctly ?	Yes	No
Signature (must be same as approval).	Date	Time
Comments about the work		

3 WORKING UNDERGROUND :

Working underground has hazards similar to working in a confined space. Therefore all precautions including entry permit mentioned in part 2.2 above should be followed.

Under ground work includes digging also. Therefore format 2 and instructions B mentioned in part 1.5.10 should also be considered.

Hazard assessment of underground atmosphere is most important. Oxygen level, measurement and removal of other gases (e.g. HS, CO, methane etc) by exhaust ventilation, artificial lighting (flameproof if necessary), necessary ladders, supports, water evacuation, safety harness, helmet, respirators, safety shoes etc. are necessary as per hazard assessment report.

See also Part 5 of Chapter 22.

4 WORKING AT THE SAME LEVEL

The common causes for such falls are slipping or tripping due to floors badly maintained, floor opening, unguarded machinery, obstacles on floor, oily material, poor lighting, poor vision or health, defective footwear, running or jumping and influence of drugs, alcohol or fatigue. Remove these defects, put guards/ barriers if necessary and warning notices as a last resort.

5 SAFETY AGAINST FALLING BODIES

Instead of persons falling, many times falling bodies hit the persons and cause accidents. Measures for safety are:

1. Wear helmet or hard hat, safety shoes and protective clothing necessary.
2. Never stand or walk under suspended load.
3. Never throw any things down from aloft or - height.
4. Place tools and materials in stable and safe position so as not to fall. Use a tool box or paint pot secured to a ladder or platform by a hook.
5. Take care in staking materials and ensure that

EXERCISE

1. Explain, State, Mention or Discuss -

1. Types of fall accidents.
2. Main causes of fall accidents and their preventive measures.
3. The kinetic energy of a falling body.
4. Statutory provisions to prevent fall accidents.
5. Which are the areas where a worker has to work at height and what precautions are necessary to work safely?
6. Usefulness of Building and other Construction Workers Act and Rules for safety while working at height or prevention of accidents due to falls of persons and materials.
7. Types of misuse of ladder and safety precautions to avoid them.
8. General requirements of scaffolding
9. Hazards and safety measures while working with -scaffolds.
10. General requirements of a safety belt.
11. Types of safety belt.
12. Hazards and safety precautions while working on a slopping or fragile roof.
13. Need and check points of a safety work permit for working at height OR in Depth.
14. General precautions while working at height.
15. The meaning and hazards of a confined space.
16. Types and hazards of a confined space.
17. Variety of confined spaces and safety measures while working in any two of them.
18. Safety while working underground.

2. Write Short Notes on

1. Incidence rate of fall accidents.
2. Indian Standards for safety of working at height and prevention of fall accidents.
3. Design aspects of stairways OR Floors.
4. Safety requirements of floors and platforms.
5. Types of ladders and their salient features.
6. Design aspect of a scaffold.
7. Pole type scaffold OR Swinging Scaffold.

8. Boatswain's chair.
9. Dismantling of a scaffold.
10. Fall arrester or Anti fall device.
11. Crawling board.
12. Conditions in a permit for digging work.
13. Hazards of working in a confined space.
14. Examples of confined spaces.
15. Engulfment.
16. Working in a sewer or gutter.
17. Main hazards of working underground.
18. Non-slip devices for ladder feet.
19. Limitations of ladder.
20. Types of anti fall systems.

3. Explain the difference between -

1. Types of fall accidents and causes of fall accidents.
2. Types of falls of persons and types of falling objects.
3. Stairways and ramps.
4. Pole (putlog) type scaffold and Outrigger scaffold.
5. Rolling Scaffold and Swinging (hanging) Scaffold.
6. Outrigger scaffold and Suspended scaffold.
7. Hazards of working at height and working in a confined space.
8. Safety precautions while working at height and those while working in a confined space.

4. Comment on the following explaining whether it is true or false?

1. Most of the falls from height (roof) prove fatal.
2. Outrigger scaffold should be the last resort if other types of scaffold are not possible.
3. Guard rail and toe board are not necessary on scaffold.
4. While working at height safety belt is fully sufficient, no other arrangement is necessary.
5. Boiler is a confined space but pressure vessel is not.
6. Tank trucks or tank wagons are not a confined space.
7. Storage tank is a confined space but a ball digester in a paper mill is not.
8. Confined space has many types of hazards.

CHAPTER – 17

Hand Tools and Portable Power Tools

THEME

1 STATUTORY PROVISIONS

Section 36A of the Factories Act states that portable electric appliance (any tool, equipment or instrument) when used in any confined space (tank, vat, chamber, pit, pipe, flue etc.), shall be of low voltage up to 24 Volt only, or other safety device like ELCB should be provided.

If inflammable gas, fume or dust is likely to be present in such confined space, portable lamp or light should be of flameproof construction.

Clause (5), Part HI of Schedule XIX, Chemical Works u/r 102 of the Gujarat Factories Rules requires all tools and appliances for work in flammable area of non-sparking type. Similar provision is also required under clause (5), Schedule XXI, Solvent Extraction Plants, under the same rule.

2 INDIAN STANDARDS

Some IS are : Safety procedures in hand operated tools §235 (PED5), SP-53. Tools - for hand, footwear 6053, handles wooden 620, handling device 4676, mason's 1630, metal cutting 10097, metal forming 6652, mining - tungsten carbide 4005, non-sparking 4595, planning 6075, 8842, threading 8778, pneumatic 5651, portable - motor operated 4665, rotating 1850, shanks - taper and automatic changers' 11173, numerically controlled machine tools 11172, steel high speed 7291, turning and planning 1983, universal, test chart 3080.

Tool and die - hot work 3748, cold work 3749, press sets of, guide posts 7664, broaching 7773.

See Part 2.2 of Chapter-15 and Part 3 of Chapter25 also.

3 HAND TOOLS

No work is finally possible without hand-held or hand operated tools. Such tools are of many types, having many purposes and operated by hand only or by some energy e.g. electric, pneumatic, hydraulic etc.

3.1 Causes and Control of Tool Accidents:

Causes of tool accidents and their safety aspects including ergonomic design are important -

3.1.1 Main Causes of Tool Accidents:

Table 5.8 in Chapter-5 states that in India, injuries due to Hand Tools were 9 fatal and 10571 non-fatal i.e. total 8.25% in 1990 and 5 fatal and 3314 non-fatal i.e. total 5.47% in 1991.

Table 5.20 states 9 & 12 fatal accidents due to hand tools in Gujarat in 1996 .& 1997. This comes to 4.91% & 4.89% respectively.

The last raw of Table 5.22 indicates that hand tool accidents (Causation No. 124) were 4.52% (710 out of 15683) in Gujarat in 1994. Thus hand tools accidents vary from @ 4 to 8% each year which need to be controlled.

USA figures of deaths due to cutting or piercing instruments or objects were 103, 108 and 132 in the year 1994, 1993 and 1992. Percentage wise these were 0.11, 0.15 & 0.15 respectively. (Accident Facts, 1997, NSC).

The causes and effects of hand tools accidents are eye injuries due to flying chips from tools, puncture wounds and infections, cut injuries due to knives, chisels and hammers, bone fractures due to defective or slipping wrenches and scratches due to scrap etc., cutting of fingers, tendons and arteries, contusion etc.

Poor maintenance, incorrect tool, wrong use, carelessness, bad storage and poor material are main causes of tool accidents.

3.1.2 Prevention & Control of Tool Accidents:

The main control measures are:

1 **The right tool for the right job:** Wrong methods are: To use file instead of pry, wrench instead of hammer, pliers instead of wrench etc. This may cause accident. Therefore it should be avoided.

2 **Tools in good condition :** Examples of poor condition are : Hammers with loose handles, screw drivers and cutting tools with broken points or broken handles, wrenches with cracked or worn jaws, dull saws, and flexible electric cables with splint insulation, broken plugs, unearthed ground wire etc. Such conditions should be removed.

3 **Tools used in the right way:** Wrong ways are: Screw drivers applied to job (e.g. to open a lid, to remove bearing), knives pulled toward the body and failure to ground electrical equipment. Tools should be used in right way.

4 **Tools kept in a safe place and safe way:** Unsafe practices are: Tools kept overhead so as to fall; chisels and other sharp tools kept in pocket or left in tool boxes with cutting edges exposed. They should be kept in a proper way.

5 **Good housekeeping for orderly layout and cleanliness:** Haphazard lying of tools anywhere, leaving tools at the workplace after completion of the job, slippery surface not cleaned, tools kept in aisles or walkways etc. are common causes of tool accidents. Tools should be kept orderly.

The supervisors and workers should be trained

1. To wear safety goggles, face shield, helmet etc as per requirement.
2. To select the right tools for each job and their right use. To return the tools after use.
3. To guard, inspect, repair and maintain tools in safe condition.
4. To use the proper storage facilities in the too room and on the work place.
5. To put the tools in such a way that they can be readily available.
6. To scrap and replace the tools when worn.
7. To check out tools at cribs.
8. To store in safe condition when not in use.

3.1.3 Ergonomic Design of Hand Tools

Ergonomic design of hand tools takes into consideration that they should :

1. Effectively perform the intended function.
2. Be properly proportioned to the dimensions of the user.
3. Be appropriate to the strength and endurance of the user.
4. Minimise user's fatigue. It should be comfortable to him.
5. Provide sensory feedback.

Some biomechanical factors to be considered in tool design are grasp, handedness (left or right, single or double), hand strength, sex and clothing.

Criteria affecting handle design are its shape, diameter, length, angulations and texture. Specific criteria are - diameter, shape, weight, section, length, angulations of and placement of handle for hammer.

Screw drivers, pliers, saws and power tools are important for ergonomic design.

See also Part 3.4 of Chapter-24.

3.2 Types and Safe Use of Hand Tools:

See Fig. 17.1 for different types of hand tools.

Main types of hand tools are as under -

(A) Metal Cutting Tools :

These are chisels, stamping and marking tools, tap and die work, hacksaws, files, hand snips and cutters.

Factors of selection and safe use are : Materials to be cut, size and shape of the tool, depth of cut, sponge rubber shield or combination of rubber hand grips and shields on hammer struck tools, use of chisel holder or tong, safety goggles, vice, wrench, right type of file with smooth handle, lubrication on cutters etc.

The flat **chisel** should have its cutting edge slightly convex. All chisels (flat, cold, diamond point or cape type) should be strong enough so as not to bend when struck. Striking face of the hammer should be slightly larger (9 mm by dia) than the struck face of the chisel. Bull chisel should be held by tongs or chisel holder to save the holder from injury.

Stamping and marking tools should be held by tool holder to keep fingers away from the tool being struck.

In **tap and die work,** hands should be kept away from broken tap ends and threads being cut.

Hack saws should be properly tightened in the frame to prevent buckling and breaking. Select proper blade (teeth per inch) for the proper metal (hard or soft) to be cut. Pressure should be applied on forward stroke only. Cutting speed of 40 to 60 strokes per minute is proper.

Selection of correct file for the job can prevent injuries, increase production and file life. A file should

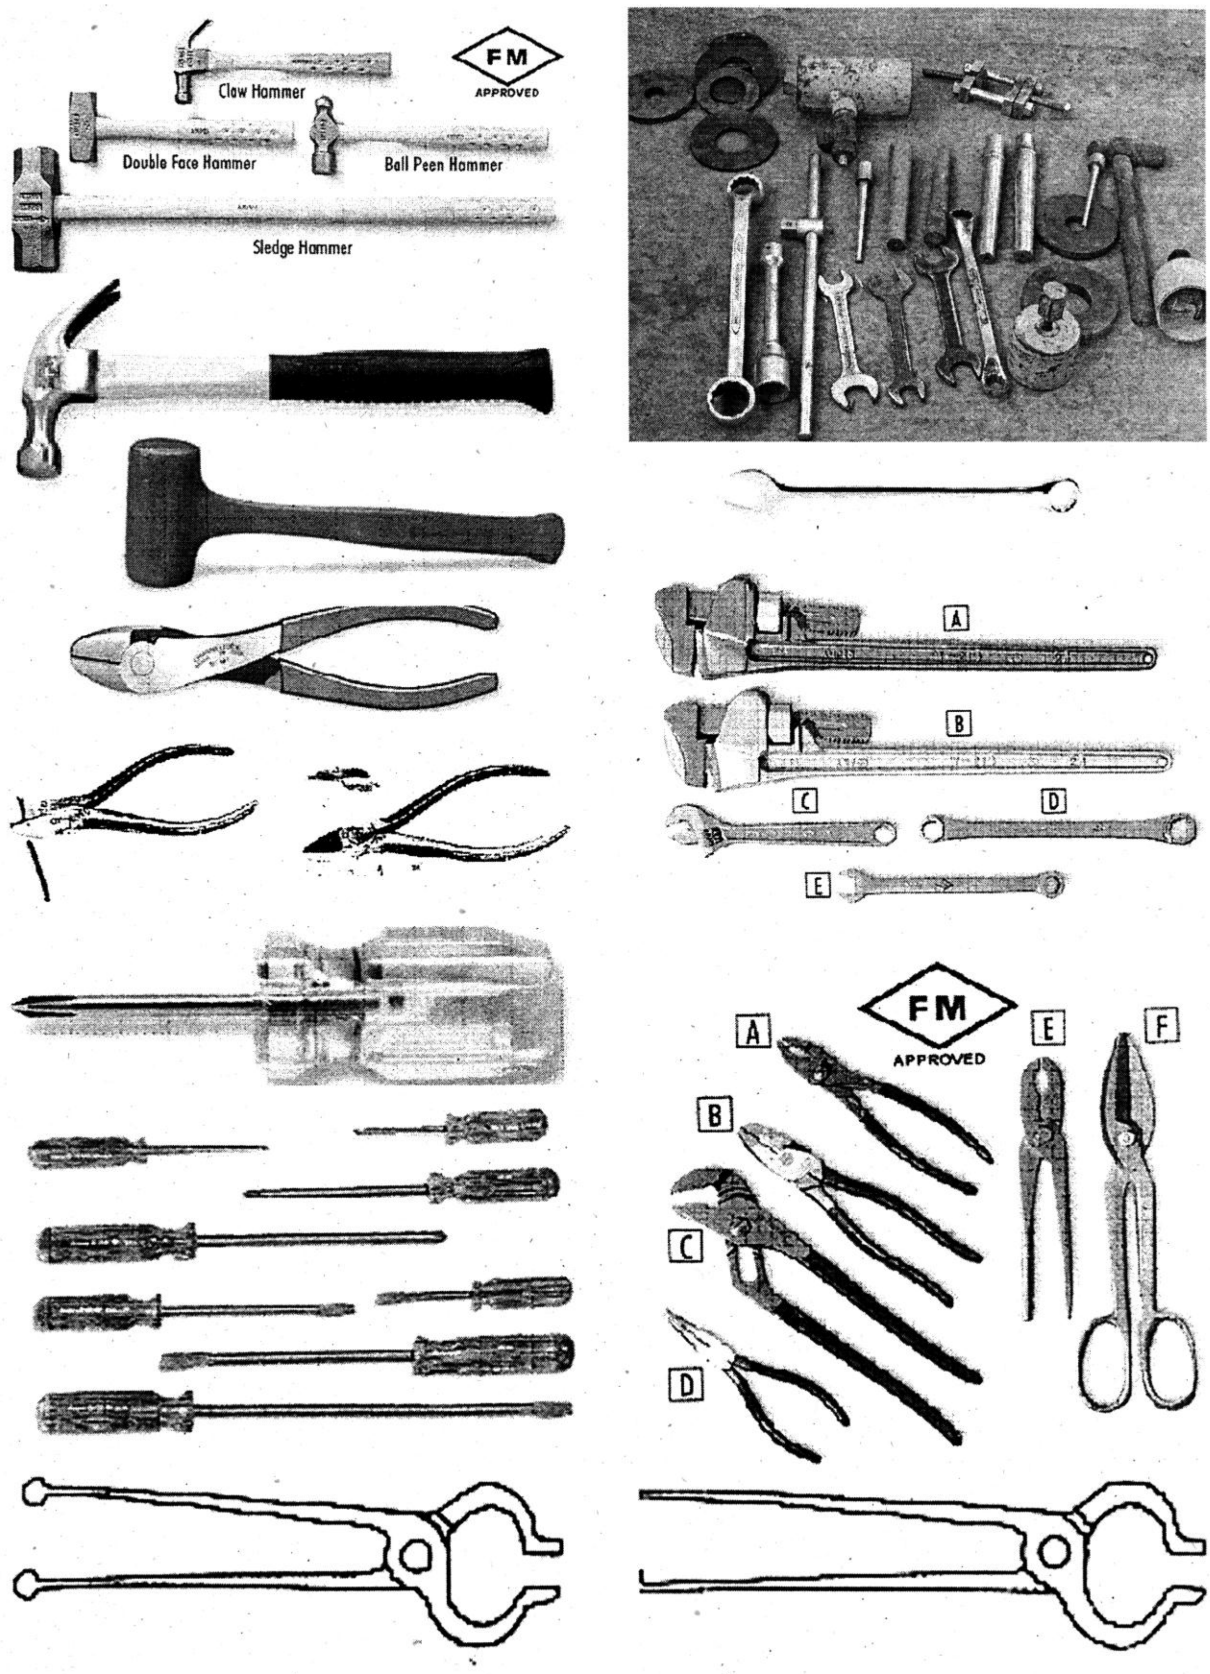

Fig. 17.1 Hand Tools

not be hammered or used as a pray. It should not be used as a punch, chisel or other tool because the hardened steel may fracture in that way.

Jaws of hand snips should be kept tight and well lubricated. Do not hammer on the handles or jaws of the snips. Safety goggles and leather or canvas gloves are necessary.

Cutters should be used to cut at right angles only. They need frequent lubrication and should not be used as nail pullers or pray bars.

(B) Wood Cutting Tools :

These are wood chisels, saws, axes, adzes and hatches.

Factors of safe use are : Proper method of holding and using the tool, splinters free handles, nail detection, sheath or metal guard on axe blade, use of safety goggles, sharp and proper cutting angle. Do not drop the tools.

The wood to be cut should be free of nails to avoid damage to the cutting edge. A wood chisel should not be used as a pry or wedge, otherwise the hard steel may break.

Proper saw (crosscut or ripping) should be selected. When not in use, saws should be wiped off with an oily rag and kept in racks or hang by handle. Nails should ,be cut by metal cutting saws.

Axes and hatches are designed to cut, trim or prune trees and soft wood. Their cutting edges should not strike against metal, stone or concrete. A narrow - bladed axe is used for hard wood and a wide axe for soft wood. Safety shoes, goggles and thick pants should be worn while using an axe.

Adzes are hazardous tools and should be used by trained workers only. Safety shoes, shin guards and safety goggles are necessary. When not in use, it should be set aside in a safe place with its cutting edge covered or left stuck in the timber.

(C) Material Handling Tools :

These are crow bars, jacks, hooks, shovels and rakes.

Factors of safe use are : Proper size and type of the tool and its handle, solid footing and' lubricating of jack, shielded point of the hook, trimmed edges and polished handles of shovels.

A **crowbar** has a point toe to grip the object to be moved and a heel to act as a pivot or fulcrum. Sometimes a wooden block may be placed -under the heel to prevent the crowbar from slipping and injuring hand.

Hooks should be sharp so that they should not slip when applied. Handles should be strong and properly shaped and attached.

Shovels should be used by proper leg positions so as not to lose balance. Edges should be trimmed and handles without splinters.

(D) Hand feed tools :

To protect hand and fingurs while working with power presses, rolling mills, press brakes, banding machines and other machineries and also working with hot matels, hand feed tools are used. They are shown in fig. 17.2.

(E) Torsion Tools:

These are adjustable wrenches (spanners), pipe wrenches, pipe tongs, machine wrench, torque wrenches, socket wrenches, open end or box wrenches, pliers, tongs, special cutters, nail band crimpers and screw drivers.

Factors of safe use are : Sharp jaws of wrenches, inspection of adjusting nut of the wrench, correct size of the wrench and not to change its dimension, insulated handles of electricians' pliers and screw drivers and screw driver not using for other purposes. A screw driver tip must be properly ground. The user should not lose balance on slipping of tool or the job.

Box and socket wrench (spanner) completely encircles the nut, bolt or fitting and grip it at all corners as opposed to the two corners grip by an open-end wrench. They cannot easily slip.

Wrench capacity should not be overloaded by using pipe extension on the handle or striking the handle as normally bus drivers do. For heavy duty work, sledge-type box wrenches are available. Penetrating oil (kerosene) should be used first to loosen tight nuts.

The use of the wrong size wrench can round the corners of the bolt or cause slippage and. make its subsequent use difficult. Makeshift approach is not good.

Adjustable wrenches should be used for light duty jobs where no fixed spanner is available.

For the reason of safety, wrenches should be pulled toward the self and not pushed.

Pipe wrenches should be prevented from slipping and falling. Its adjusting nut should be checked frequently. If it is cracked, the wrench should be withdrawn from the use. A pipe wrench should be used for pipes and their fittings only and not for nuts and bolts because their corners can break the teeth of the wrench, thereby making it unsafe to use later for pipe work. It should also not be used for soft metal (brass, copper) valves or fitting which can be crushed or bent out of shape.

Pliers are meant for gripping and cutting operations and should not be used as wrenches. A

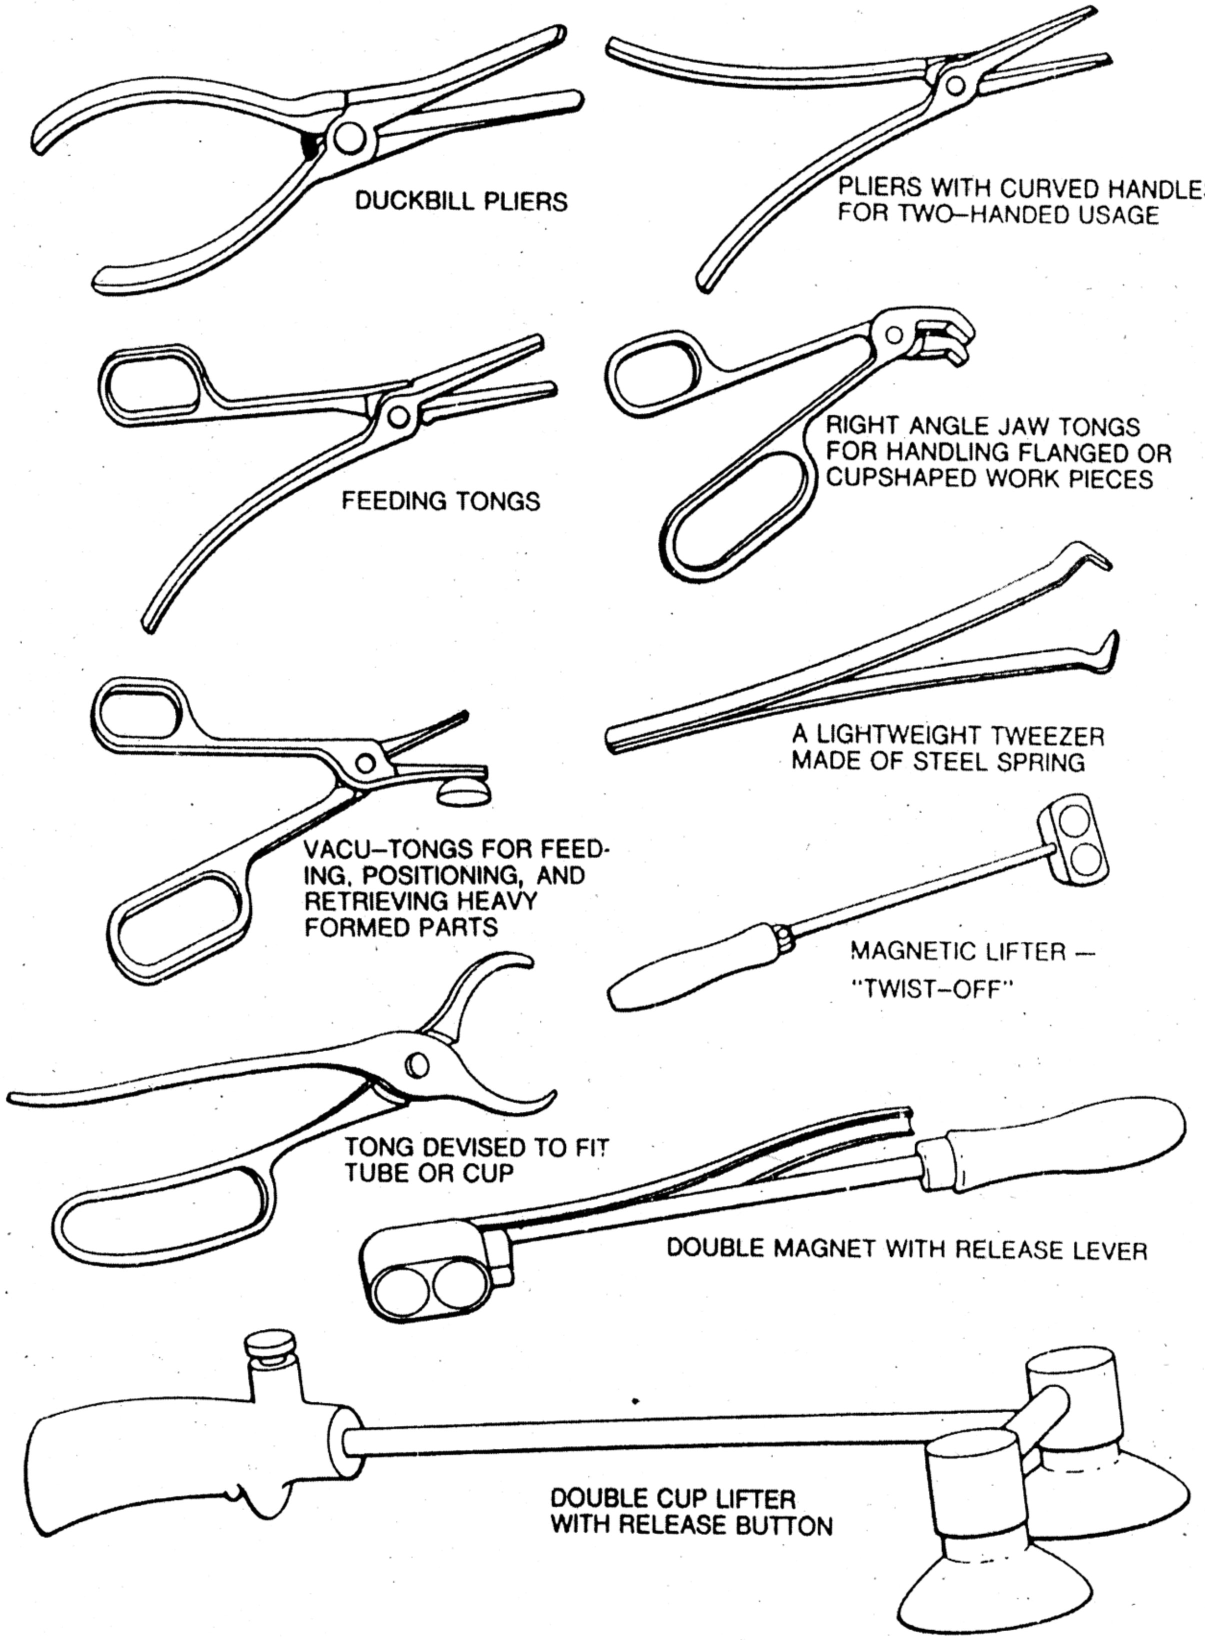

Fig. 17.2 Examples of hand feed tools (from OSHA 3067).

guard cover on cutting edge of side-cutting pliers can prevent flying short ends. Pliers for electrical work must be insulated and simultaneous use of electrician's shock-proof gloves is also necessary.

Pullers are used to pull out gear, wheel, pulley, bearing etc. from a shaft. Prybars and chisels should not be used for this purpose.

Screwdriver tip must be properly ground to fit the slot and it should be of the correct size for the head. Handle should not be hammered. For electrical work, handle should be insulated. Screws should not be overtightened to avoid slipping.

(F) Shock Tools:

These are hammers, sledge hammers, riveting hammers, carpenter's or claw hammers. The handles should be smooth and of proper size.

(G) Non-Sparking Tools for Hazardous area :

Such tools of non-ferrous (Beryllium, copper alloy, brass, copper, lead, plastic, rubber) materials are used where flammable gases, volatile liquids and explosive substances are stored or used. They should be kept free of picked up foreign particles to avoid friction sparks.

Hazardous area classification (Part 8.1 of Chapter II) should be known first before selecting hand tools. In most hazardous area where high risk of fire or explosion exists, non metalic ie. wood, rubber or plastic tools should be used if possible and proper earthing of equipment should be ensured. There should be flameproof electric lighting arid if hand lamp is to be used, it should not be of more than 24 V. Working in day lighting should be preferred.

For use of welding/cutting tools, statutory provisions (viz. Sch. 24 of GFR) should be strictly followed.

Necessary PPE for working in hazardous area should also be used.

They cannot be used to apply heavy stroke. Therefore careful use is necessary. It should be properly selected.

(H) Miscellaneous Cutting Tools :

Planes, scrapers, bits, drawknives, ice picks and brad awl are used for special purposes.

Knife accidents are many. A handle guard or finger ring on the handle of knife and the cutting stroke away from the body are desirable. Knives should be carried over the right or left hip toward the back. This will prevent severing a leg artery or vein in case of fall. Knives should not be kept mixed with other tools. Knives should not be used in place of screwdrivers, can openers or ice picks.

All such tools should be kept sharp and in good condition. When not in use, they should be placed in a rack on the bench or in a tool box in such a way that will protect the user as well as the cutting edge.

Carton cutters are safer than hooked or pocket knives for opening cartons as they eliminate deep cuts that could damage inner contents.

While walking or climbing on ladders, workers should use a strong bag, bucket, tool hoist belt or pouch to hold tools safely and to keep both hands free for safe moving and working. Sharp tools should not be put in pockets. Tools shall never be thrown on ground. Tools should not be put on vibrating or slippery overhead surfaces, ladder step, scaffold plank, overhead piping or part of any structure or machine from .which they can easily fall or hurt.

While giving tool to another person, the handle should be toward the receiver. While turning around, care should be taken not to strike others.

Misuse of hand tools can cause injuries. Use of hand tool with power driven machinery (e.g. lathe) should be controlled. Training is necessary for their safe handling and use. Use of safety goggles and setting up a shield or screen to prevent injury to others from flying particles, sparks, excessive light, radiation etc. are also required.

Indian Standards should be followed for design, selection, use and maintenance of above tools. See Part -2.

3.3 Centralised and Personal Tool Issue System :

The main advantage of such tool control is the uniform inspection and maintenance of tools by a trained man. It facilitates the effective records of tool failure, accident causes and suggestions for improvement. It provides positive control than scattered storage. Tools are well maintained and less exposed to damage, deterioration .and falling hazards.

The central tool control room attendant can advise and issue the right type of tool, ask to return the damaged or worn tool and encourage the safe use of tools. He can also suggest the appropriate type of personal protective equipment at the time of issuing the tool and make arrangement to get clean and to well maintain the tools after and before issue.

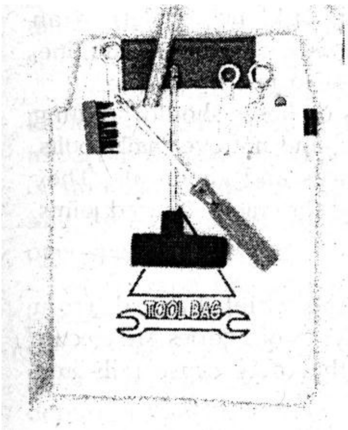
Methods of service, repair and reconditioning should be established. Supervisors should frequently, at least weekly, inspect all tools and remove from service those found damaged. A checklist of inspection can also be designed and used.

It is the employer's responsibility to see that the employees are provided with and use the safe tools in safe methods.

3.4 Purchase, Storage and Supply of Tools:

Careful purchase of hand tools can eliminate hazards from beginning. Standard (IS & others) and approved type of tools should be ordered for purchase. Material of construction, quality, durability, ergonomic design, good handle and insulation, effective cutting edge and electrical safety with electrical tools are some of the points for better selection. Purchase of tool boxes, chests, cabinets, belts and pouches also needs attention. In-charge of a central purchase department should fix the criteria or guidelines for best quality tools. Advice of the safety committee and experienced supervisors and workers should also be taken.

Storage of tools should be in a dry cool place and away from any chemical effect. Tools should be kept in a tool box. Proper cupboard, rack or shelves should be used to put tool boxes. Shelves may be movable so that workers can reach all sections to get their tool boxes out.



Tool boxes should be used to put and carry the tools. A tool box should have handle, catch or a hasp and locking arrangement. Bigger tool boxes having more drawers or trays are called tool chests. Mobile tool cabinets are bigger tool chests and move on wheels. Depending on size, weight and number of tools, proper type of tool box, chest or cabinet should be selected.

Supply of tools may be from a central tool room or through supervisors on need-base system or allotted to the worker to keep with him in his tool box. It should be ensured that the tool should be of good quality and in safe and good working condition. Supply includes replacement of damaged or worn tools. A record of purchase date, service condition, repair and maintenance can be useful in this regard.

Tools should be in sufficient number so that it can be supplied or replaced individually and work is not suffered because of any waiting time. If this is not possible, working time of the tool should be so scattered and planned to minimise the waiting period. Time of supply should be during working hours and suitable to the workers.

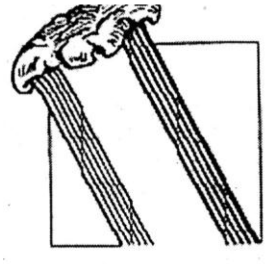
3.5 Causes of Tool Failure :

They are : overheating or under heating of the forging of steel when it was hardened, cracks from improper forging, improper tampering, failure to relieve stresses in forging, improper quenching, incorrect angle of cutting edge or steel of poor quality.

Defects of these types will be found in tools of inferior construction, which, because of breakage and inefficiency, are more expensive in the long run than are tools of the best quality obtainable.

3.6 Inspection, Maintenance and Repairs of Tools :

The tool room attendant or tool inspector should be qualified by training and experience to pass judgement on the causes or defects of tool failure stated above and condition of tools for further use. No dull or damaged tools should be given for work.



Efficient tool control requires periodic inspection of all tool operations. Responsibility for such periodic inspection should be placed with a top man, preferably the department head and should not be delegated by him..

Hand tools receiving the heaviest wear, such as chisels, wrenches, hammers, sledges, star-drills, blacksmith's tools and cold cutters require frequent maintenance on a regular schedule.

Repair facilities require work benches, vices, hardening or tempering furnace or forge, tempering baths, goggles, repair tools, grinders, fasteners and good lighting. Enough stock should be maintained to replace and issue safe tools.

3.7 Tempering, Safe Ending, Dressing and Handles of Tools :

Tempering of Tools: Hammer-struck and striking tools (chisels, stamps/punches, cutters, hammers, sledges and rock drills) should be made of carefully selected steel and heat-treated so that they are hard enough to withstand blows without mushrooming excessively and yet not be so hard that they chip or crack.

For safety, it is better that shock tools, some of which can be dressed frequently, be a little soft rather than too hard, because a chip may fly from an excessively hard tool without warning when the tool is struck with a hammer or sledge.

Forming and tempering of tools is a skilled operation. Before heat-treating any tool, the exact analysis of tool or recommendations for its proper heat treatment should be obtained.

Safe-ending of Tools : Hammer-struck tools, such as chisels, rock drills, flatters, wedges, punches, cold cutters and number dies should have heads properly hardened by a qualified workman. The hazard of burred heads can be reduced by safe-ending the tool. This can be quickly and economically achieved by grinding or flame cutting a shoulder recess about 1/8 inch wide and 1/4 inch deep into the tool head and then bronze-welding it. The proper base-metal temperature for bronze-welding is 1600° to 1700° F. The correct temperature is indicated by a bright red colour when the tool is looked at through dark glasses in the light of oxyacetylene flame.

Short sections of tight-fitting rubber hose can also be set flush with the striking ends of hammer-struck tools to keep chips from flying.

Dressing of Tools : Shock, cutting and pointed tools require regular maintenance of their edges or striking surfaces. Once the cutting or striking surfaces have been properly hardened and tempered, only an emery wheel, grindstone, file or oilstone need be used to keep the head in shape and the edges clean and sharp. Proper precautions should be taken before grinding hardened tools. They should not be ground until they have been drawn or tempered. Grinding should be done in easy stages with no attempt to take off much metal at one time. While grinding, the tool should be kept as cool as possible with water or other cooling medium. The manufacturer's recommendations for type and kind of grinding wheel should be followed. Each cutting edge should have the correct angle according to its use and be finished off with a file.

Redressing of Tools : Redressing or reshaping of tool edges or surfaces which are badly damaged is not recommended. It should be discarded.

Procedure for correct redressing of dull cutting edges is as under :

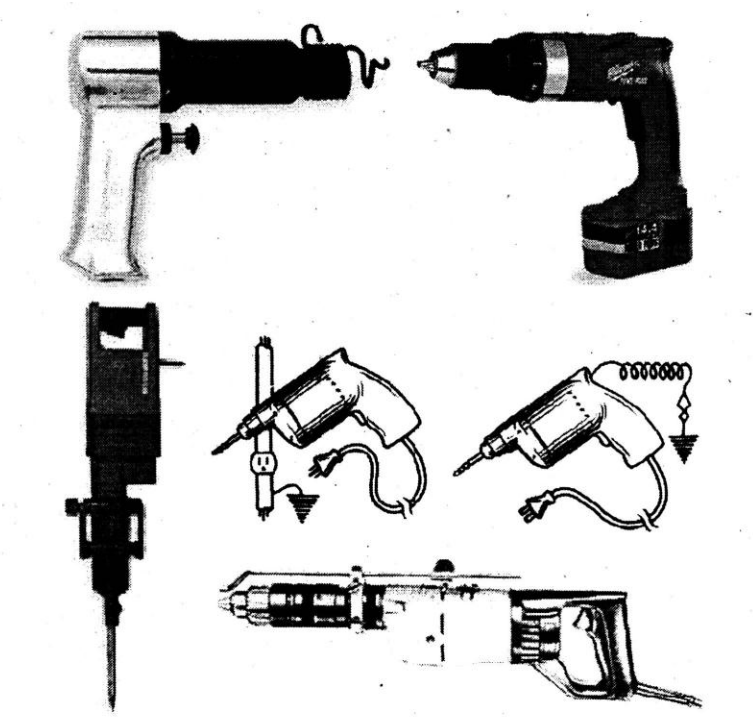
1. The tool edge should be supported firmly.
2. File or stone away from the cutting edge. Do not use a grinding wheel.
3. Restore the original contour of the cutting edge.

Handles : The handles of the tools should be of the best straight-grained material. Fitting of handles is very important. Poorly fitted handles make it difficult for the worker to control the tool. Design criteria for handle are its shape, diameter, length, angulations, texture and ergonomic aspects for convenience and safe use.

Handles should be fitted or replaced by an experienced person. Long use or shrinkage can loosen the handle. Wedges can be inserted in gap, tool head can be further driven in the handle with wedges reset and the protruding end of the handle cut off. If this is not possible a new similar handle, should be fitted after removing the old one.

4 PORTABLE POWER TOOLS

4.1 Types, Hazards and Safe Use :



Portable power tools are divided into five primary groups according to the power source : electric, pneumatic, hydraulic, gasoline and explosive (powder actuated). Several types of tools such as saws, sanders, drills, and grinders are common to the first three groups; whereas explosive tools are used exclusively for penetration work, compression and cutting. Pneumatic grinders, impact tools and flexible shafts tools are also in use. Hydraulic tools, are used mainly for compression work. .

A portable power tool presents similar hazards as a stationary machine of the same kind, in addition to the risks of handling. Typical injuries caused by portable power tools are burns, cuts and strains. Sources of injury include electric shock, flying particles in the eyes, fire, falls, explosion of gases and falling tools.

The power line should always be disconnected before accessories on a portable tool are changed, and guards should be replaced or put in correct adjustment before the tool is used again.

Care should be taken to set power driven tools in safe area where they may not be struck by passersby and activated. A tool should not be left in an overhead place where there is achance that the line, if pulled, will cause the tool to fall.

Flexible cords, cables or hoses should be hung overhead and on safe points, and not over nails, bolts, sharp edges, oil, hot surfaces and chemicals. They should be frequently checked for cracks/opened joints, cut phases or earth wires.

Electric Tools:

Electric shock is the chief hazard from electrically powered tools. Types of injuries are electric flesh burns, minor shock that may cause falls and shock resulting in death.

Main safety points for electric power tools are:

1. Flexible cable (cord) should be protected from misuse, abuse and damage to insulation resulting in broken or exposed live conductor.
2. Plug-socket connection should be tight and safe. No bare conductors should be inserted in plug. Three pin top should be used.
3. Metal casing should be effectively earthed. Earth .core of the flexible cable should be properly connected to the metalwork to be handled. Flexible conduit is not suitable for this purpose.
4. Second alternative is the use of 110 V supply with centre tapped to earth to reduce an effective shock voltage to 55-a relatively safe voltage.
5. Power cutting switches should be within reach and near the apparatus.
6. Regular maintenance to check earth core continuity and strength of earthing.
7. Additional back-up protection is ELCB. i.e. earth leakage circuit breaker which detects the current difference between power supply line and current returning to the supply point. In normal safe operating condition, this current difference is zero but if there is a fault and leakage starts to earth, a differential current occurs which operates the device that rapidly senses and trips its contacts to cut off power to the apparatus. See Part 6.2.3 of Chapter - II.
8. Electric tool should never be put in wet area or used in raining condition.
9. Double protection or double-insulated or all insulated type equipment which need not be earthed.
10. Dead man control. This tool operates till the button is pressed and it stops as the button is released. Portable saw, hoist and remote control pendant are of this type.

While using electric drills, saws and grinding wheels,' eye protection is always required. Drill bit should not be of excessive length, otherwise it may break. Electric saws should have guards. Circular saw (portable) should be equipped with a trigger switch that shuts off power when pressure is released. It will not run when not in use. Grinding wheel should be properly mounted and guarded.

Sanders should run away from the body as it cannot completely guarded. Dust should be cleaned daily by a low pressure (30 psi or less) air and wearing safety goggles. Vacuum cleaning equipment is safer.

Pneumatic or Air-powered tools are less hazardous than electric power tools. Grinders and impact tools have air hoses (pipes) which pose tripping or stumbling hazard. Self-storing recoiling air hoses are safe. Speed regulator or governor is necessary to avoid over-speeding the tool.

Impact tools include riveting guns and jackhammers. Air pressure safety valve, automatically closing valve actuated by a trigger located inside the handle (machine can run only when the trigger is depressed) and retaining device that holds the tool in place so that it cannot be fired accidentally from the barrel are necessary.

Air should be filtered and cooled moisture or water should be removed from the tool. Pneumatic tools are of two types - percussive and rotary. In rotary tool either piston and cylinder or rotor vanes are used. Speed regulator is necessary. Pneumatic tools are started and stopped by means of shut off valves and rotary valves. Rotary valves are equipped with a spring returning the rotary handle to its 'stop' position as soon as the handle is released. Maximum operating pressure is 6 bar. Additional handle is provided to control back twisting torque when the cutting tool (e.g. drill, reamer) gets jammed.

Effects of noise and vibration cause health hazards. Vibration and jerks cause strain in the joints and disease. 'White fingers' or 'Vasospastic vibration syndrome' is a disease due to vibration exposure and vascular spasm. 8 to 16 Hz frequency causes' the most harmful effects as it generates resonance in hand-arm system. Safe limit of vibration intensity i.e daily exposure is

60 HZ for 1 hour working and

112 HZ for 30 minutes working.

To reduce vibration, damping springs, air cushions and vibration absorbing handles are necessary.

Noise level near the tool should be measured and ear protection should be given to the operator if necessary. Eye protection is required due to flying chips. Two chippers should work away from each other, back to back, to prevent cuts from -flying chips. They should not point a pneumatic hammer at anyone. Neither should it be used to clean dust from clothes due to risk of intestine inflation. Jack hammer handles should have rubber grips to reduce effects of vibration and fatigue. Operators should wear metatarsal - type safety shoes to protect against fall of heavy hammer.

See Chapter-12 for Noise and Vibration.
See Part 3.4 of Chapter-24 also.

Hydraulic power tools are hydraulic chain saws and compression devices. A small leak can impose high oil pressure on finger. Therefore, proper pressure hose should be selected. Safety pins are provided to shear at pre-set pressure. Pins should be secured by retainers. Poor quality shear pins, improper design or use of sockets can cause sudden failure and result in flying missiles.

4.2 Selection, Inspection, Maintenance and Repairs :

Information and training to select right tool for the right job is necessary. If a small hole is to be drilled and if it is easily possible by a hand drill, power drill is not necessary. Manual hazards are less serious than the power hazards.

Tool supplier should be given complete information about the job for which a tool is required so that he can recommend the most appropriate tool for that job.

Normally portable power tools are to be used on light or home work. For continuous operation and production service or heavy work, 'industrial duty' tools are selected.

Periodic inspections are necessary to find defects and to keep the tool in good working condition. Then it serves the purpose of preventive maintenance. It prevents hazards and costly breakdowns. Defective tools should be tagged and repaired.

Record of date of inspection, fault noticed and date of repair is necessary. Cause of fault and detail of repair carried out can also be added to such record.

Workers should be trained to inspect tools, identify defects, report and repair. They should be warned not to do makeshift repairs and to do no repair work unless authorised.

For cleaning purpose non flammable and nontoxic solvent should be used.

Inspection Checklist

General : Low voltage equipment used in tanks and wet area? Tools well maintained? Motors in good condition? Approved tools used in explosive atmosphere? Tools left where they cannot fall?

Cords : Insulation, plugs and sockets unbroken? Cords protected against trucks & oil? Cords not in aisle?

Grounding : Ground wire fastener in safe condition? 3-wire plug extension cord? Defects or minor shocks reported?

Guarding: Guards used on grinders & saws? Movable guards operate freely? Eye & face protection worn?

4.3 Use of Personal Protective Equipment:

Gloves, loose clothing and jewellery should not be worn by workers using revolving tools such as drills, saws and grinders. The weight of most power tools makes it advisable for users to wear safety shoes (with steel toe) to reduce chances of injury, if the tool falls or drops.

While working at overhead places with power tools, the operator should wear a safety belt and use a good platform or support.

Dust type respirators should be worn on buffing, grinding or sanding jobs which produce harmful dusts.

Ear protection is necessary at high noise levels.

Safety goggles or face shields should be worn for work on grinders, buffing wheels and scratch brushes because the unusual positions in which the wheel operates will cause particles to be thrown off in all directions. For this reason, protective equipment is even more important than it is for work on stationary grinders.

Eye protection equipment (safety goggles or face shields) is a must in all operations where hardened metal tools are struck together, where wood working or other cutting tools are used, where anything is struck by a metal hand tool, or where the cutting action of a tool causes particles to fly. Clothing should be free of oil, solvents or frayed edges to minimise fire hazard from sparks.

EXERCISE

1. Explain, State, Mention or Discuss -

1. Causes and control of tool accidents.
2. Wrong methods to use hand tools.
3. Merits and demerits of centralised tool issue system.
4. Different types of hand tools and factors of their safe use.
5. Types of material handling tools and factors of their safe use.
6. Types of torsion tools and safe methods of their use.
7. Types of portable power tools and their safety aspects.
8. Safety aspects of using electric power tools.
9. Types of pneumatic power tools, their main hazards and control measures.
10. What type of PPE is required while working on which type of portable power tools?
11. Hazards and control of portable power tools.
12. Main causes and control of hand tools vis-avis. power tools.
13. Types of defects in hand tools.
14. How hand tools are misused? What are the methods of right use?
15. A safety programme for control of hand tool accidents.

2. Write Short Notes on

1. Ergonomic design of hand tools.
2. Criteria for careful purchase of hand tools.
3. Safe storage of hand tools.
4. Tool boxes.
5. Causes of tool failure.
6. Maintenance and repairs of hand tools.
7. Dressing of hand tools.
8. Handles of hand tools.
9. Metal cutting tools.
10. Wood cutting tools.
11. Correct and wrong use of screw-driver.
12. Non-sparking tools.
13. Knife accidents.
14. Safe methods to use portable power tools.
15. White finger disease.
16. Safe methods of using air-powered tools.
17. Noise and vibration control of pneumatic tools.
18. Hydraulic power tools.
19. Inspection checklist for portable power tools.
20. Double insulation.
21. Fail safe design of a portable power tool.
22. Main causes of hand tool injuries and remedial measures for them.
23. Safe practices to be followed in the use of hand tools OR power tools.
24. Spark resistant tools.

3. Explain the difference between

1. Centralised tool issue system and personal tool issue system.
2. Tempering of tools and safe - ending of tools.
3. Dressing and redressing of hand tools.
4. Metal cutting tools and wood cutting tools.
5. Chisel and File.
6. Hack saw and cutter.
7. Crowbar and shovel.
8. Pliers and pullers.
9. Double protection and Dead man control.
10. Shock tools and torsion tools.

4. Comment on the following explaining whether it is true or false

1. No work is finally possible without hand-held or hand operated tool.
2. It is wrong belief that non-sparking tools are safe.
3. Electric drill should not be used in wet condition.
4. Earthing of portable electric grinder is not necessary.
5. Trained purchase officer is necessary for ordering

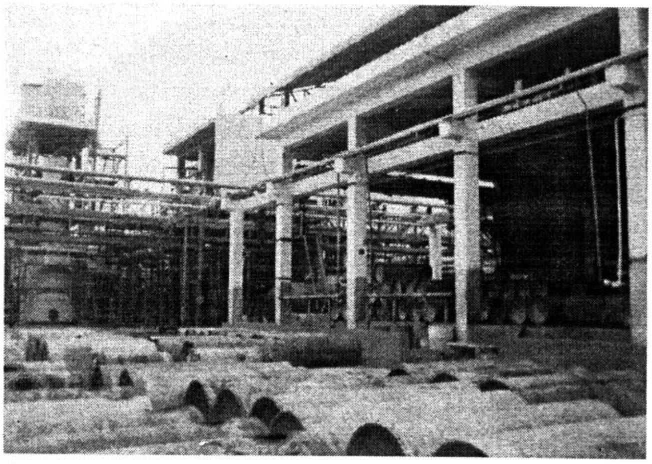
CHAPTER – 18

Safety in Chemical Industry

THEME

1 INEVITABLE PLACE CHEMICAL INDUSTRY



The safest and simplest wav to avoid chemical Hazards and their ill-effects is to avoid chemical industry itself. But is it possible ? A place of chemical industry can be selected or shifted but it has to run somewhere on the earth and its place in our life has become inevitable because of the following reasons -

1. In homes we need cement, plaster, tiles, paint, plywood, glass, plastic, curtains, TV, tubes etc.
2. In kitchen we want gas, fuel, matches, heating appliances, metal or ceramic dishes etc.
3. For health we need drugs, pharmaceuticals, cosmetics, perfumes, talc etc.
4. Agriculture needs fertilisers and pesticides.
5. Construction requires minerals, metals, lime, cement, explosives etc.
6. Transportation needs petrol, diesel, gas, paints, rubber etc.
7. Clothing requires dyes, colours, soaps, detergents and a variety of chemicals.
8. In offices we want paper, ink, adhesives, photocopies, computer etc.
9. Basic needs like air, water, food, clothing and shelter are the product of chemistry.
10. Our human body itself is an astounding chemical industry carrying wonderful chemical processes within it.

All above materials are made from elements and their compounds and by direct chemical processes or indirect chemical treatment. Therefore, human life is becoming more and more dependent on chemicals making the place of chemical industry in society inevitable.

Chemical industry is also useful for national production and employment for many people.

It is, therefore, not possible to avoid or prevent chemical industry and the only way remains for us is to run this industry safely by identifying, avoiding and controlling its hazards. This, in turn, suggests the following ten-point safety programme :-

1. Study and identify chemical hazards using material safety data sheet (MSDS) and a system of classification, packaging and labelling should be developed.

2. Select safer technology.

3. Select safer siting of chemical industry for minimum loss to men, material, environment etc.

4. Design and construct the factory with all safety precautions from the very beginning.

5. Workplace hazards inside the factory should be controlled by good engineering controls, safe work methods or operating procedure and using personal protective equipment.

6. All requisite safety devices, fittings, instruments, equipment, machines etc., must be provided and well maintained.

7. Workers must be properly trained for safe operation of the plant and their role in emergency planning and control.

8. Safe transportation and handling of hazardous chemicals within and out-side factory premises.

9. Safe disposal of hazardous wastes within and outside factory premises.

10. Well monitoring and control of hazardous substances at work places and of occupational ill-effects and diseases by pre and periodical medical examinations of the workers.

2 NEED OF SAFETY IN CHEMICAL INDUSTRY

Though safety in each field is of equal importance, safety in chemical field needs more attention because of its specific nature. Chemical safety seems more complicated than civil, mechanical or electrical safety because each chemical has many properties, many processes, many hazards and many controls. The state, pressure, temperature, process parameters etc., are also changeable. Many hazard data and complete reaction documents are still not available. Many hazards are known after the accident only as in case of Bhopal and so many incidents. Engineering controls may not be possible or available at many places. Control devices and personal protections are inadequate many times. Warning devices may either not be available or not be functioning well. All these diversified working conditions and operational situations pose many dangers which need their proper knowledge and attention followed by proper safety measures and proper preventive as well as corrective maintenance.

Once upon a time textile factories were dominating in our country, but chemical factories, small and big, have been extensively increased. Process wise the highest number of factories in Gujarat are of chemical and chemical products. Table 5.16 of Chapter5 shows 501 (Total of NIC Group No. 30 & 31) out of total 21220 i.e. 2.36% chemical factories in the State in 2001. Employment wise it employed 24803 workers out of total 907101 i.e. 2.73% in the State. Table 5.21 states that accident wise also it is second (next to textile) contributing 1090 out of 12131 i.e. 8.98% accidents. The percentage of fatal accidents in chemical factories was 30.89% in 1997 in Gujarat.

Indian statistics of 1979 states that there were 9485 (Total of NIC Group No. 30 & 31) out 135173 i.e. 7.01% chemical factories and 609000 out of 6797000 i.e. 8.95% workers in these factories. As the latest all India statistics is not available, it is estimated that this percentage would have reached up to 10%. During 1992 there were 4141 out of 64631 i.e. 6.40% accidents in chemical factories which can also be estimated to rise up to 8% during last 6 years.

Thus it can be concluded that there are about 10% chemical factories in India, employing 10% of total manpower and contributing @10% of total accidents.

In Gujarat, considering subsequent growth of chemical factories, they are @21%, employing @21% of total manpower, contributing @9% of total accidents and@31% of fatal accidents.

Bhopal accident is remarkable. It caused more than 2500 deaths, many more injuries and became world famous attracting everybody's attention toward chemical safety. It has opened the eyes and shaken the governments and all safety people to wake up. Many expert committees have been formed and safety reports are published. The Factories Act is rapidly amended to include many matters on chemical safety. Many seminars have been held and the chemical wave is still continued. This shows the significance of chemical safety.

Before understanding safety aspects of a chemical industry, it is utmost necessary to study or refresh basic concepts of chemistry and chemical technology. For this purpose, please refer Chapter-32, Tables I to 4 before proceeding further.

3 TYPES OF CHEMICAL INDUSTRY

Before proceeding toward general safety aspects it is essential to have a look on variety of chemical industries and to realise a very wide scope of the subject. Thousands of volumes are available on chemicals, their processes, effects and control measures. But it is a fact that out of lacs of chemicals, published data of their dangerous properties is available for a few thousand only. Therefore most of the unknown chemicals must be handled very carefully. This requires basic knowledge of chemical safety. General knowledge is always useful for any type of chemical industry. The 27 dangerous operations, 29 hazardous industries and 29 notifiable occupational diseases due to such chemical industries are given in Parts 6.5 to 6.7 of Chapter-4.

National Industrial Classification (NIC-1987) Major Group No. 30 lists 50 types of chemicals and chemical products industries and Major Group No. 31 lists 35 types of rubber, plastic, petroleum and coal product industries. But this is still a broad classification and types of chemical factories are day by day increasing.

The chemical industries needing more attention are petroleum refineries, petroleum product industries and industries for basic heavy inorganic and organic chemicals, fertilisers (organic, inorganic or mixed), pesticides, dye-stuffs, paints, solvents, LPG, acids, alkalis and dangerous gas, toxic, flammable and reactive chemicals.

4 STATUTORY PROVISIONS

The Factories Act contains specific provisions on chemical safety. Section 2 (cb) defines 'hazardous process'. Section 7A and 7B specify general duties of occupiers and manufacturers for health and safety. Sections II to 20 regarding cleanliness, disposal of wastes and effluents, ventilation and temperature/dust and fume, overcrowding, lighting, drinking water, latrines, urinals and spittoons are all useful for chemical factories also. The whole chapter-IV (Sections 21 to 41) on safety is also relevant. Provisions of hoists and lifts, lifting machines, revolving machinery, pressure plant, floors, stairs and means of access, pits, sumps, openings in floors, excessive weights, protection of eyes, precautions against dangerous fumes, use of portable electric light, explosive or inflammable dust, gas etc., fire and building safety are also useful in chemical factories.

Chapter IV A (Sections 41 A to 41 H) regarding hazardous processes provides for site appraisal committees, disclosure of information, health and safety policy, medical examination (pre and post employment) of workers, health records, supervision, emergency standards, permissible limits of toxic exposure (Second Schedule), safety committee, duty to warn about and remove imminent danger.

Chapter V (Sections 42 to 50) on welfare provides for washing facilities, cloak room, first-aid, ambulance room, canteen, rest and lunch room, creche and welfare officer. Sections 87 to 91 A regarding dangerous operations, notice of accidents and diseases, inquiry, samples and health surveys are also useful. Section 87A prohibits employment on account of serious hazard. Section 96A for penalty for breach of section 41B, 41C or 41H is very severe. By section 104A burden of proof is shifted on a person who fails to fulfil the duty under this Act. Section IIIA creates worker's right to get information relating to their health and safety and to get trained for that. The Third Schedule lists 29 occupational diseases most of which are due to chemicals.

The Gujarat Factories Rules provide many rules under above sections of the Act. Rule 54, schedule IV for rubber mills, rule 61 for pressure plant, rule 63 for protection of eyes, rule 66 and 66A for fire safety, rule 102 and twenty six schedules there under (see Part 3 of Chapter 27), rule 103 and 104 for notice of accidents, poisoning and diseases are more important for chemical factories. Rule 61B for reaction vessels and kettles, rule 68C for polymerising and curing machines, rule 68D for thermic fluid heaters, rule 68E for fragile roofs, rule 68G for ovens and dryers, rule 68H for ship building, repairs and breaking and rule 68J for hazardous chemicals and processes suggest many safety measures.

Rules 68K to N, P & Q provide for disclosure of information to workers, CIF etc. and MSDS, rule 68R for health records, rule 68S for supervisors, rule 68T for medical examination, rule 68U for occupational health centime, rule 68V for ambulance van and rule 68W for decontamination facilities.

Amendment of 1995 (w.e.f. 15-2-95) in the Gujarat Factories Rules 1963, has added many details for chemical factories and for safety, health and welfare of the workers. Newly added following schedules, u/ r 102, must always be referred for strict compliance

Sch. 19	-	Chemical Works
Sch. 21	-	Solvent Extraction Plant
Sch. 22	-	CS_2 Plant
Sch. 25	-	Pottery, and
Sch. 26	-	Foundry.

See Chapter-23 for details of above mentioned provisions industry wise.

Other Laws on chemical safety include the Boilers Act 1923, Gujarat Boilers Rules 1966, Indian Boiler Regulations 1950, The Petroleum Act & Rules, The Explosive Act & Rules, The Insecticide Act & Rules, The Poisons Act & Rules, The Electricity Act & Rules, Gas Cylinder Rules 1981, Static and Mobile Pressure Vessels Rules 1981, Water and Air Pollution Control Acts and Rules, Environment (Protection) Act 1986 and Rules, Hazardous Waste Management Rules 1989, MSIHC Rules 1989, Chemical Accidents (EPPR) Rules 1996, Bio-Medical Waste Rules 1998, Building and Construction Workers Act 1996 and Central Rules 1998, Atomic Energy Act, Radiation Protection Rules etc. See Chapter-28 for all such Acts and Rules.

As the details of all above provisions are readily available in statute books, they are not reproduced here. It is recommended to refer them for details as they are directly applicable and create legal responsibility also.

5 INDIAN STANDARDS

Sectional lists of Indian Standards on chemical, Indian Standards on safety and BIS Handbook are readily available at Bureau of Indian Standards Offices. Each industry should select applicable INDIAN STANDARDS booklets from these sectional lists. They are most useful. A sample list is given below :

Code of Safety for Acetic acid 5208, acetic anhydride 5302, acetone 7445, air purifying canisters 8318, ammonia 4544, aniline 7415, benzene, toluene & xylene 4644, bromine 6953, calcium carbide 6819, carbon disulphide 5685, caustic soda 4264, laboratory safety 4209, 4906, glossary of terms, chemical and radiation hazards 4155, glossary of terms, respiratory protective devices 8347, glossary of terms, explosives 10081, chlorine 4263, classification of dangerous goods 1446, classification of hazardous chemicals and chemical products 4607, ethylene oxide 6269, cryogenic .liquids 5931, hydrochloric acid 6164, lead and its compounds 4312, LPG installation 6044 (Part I & II), mercury 7812, methanol 7444, nitric acid 4560, phenol 6270, phosgene 8185, sulphuric acid 4262, vinyl chloride monomer 9786.

Code of safety for Hydrochloric acid 6164, chlorosulphonic acid 6156, hydrofluoric acid 5184, aluminium chloride, anhydrous 9052, phosphoric acid 6818, caustic potash 6954, phthalic anhydride 7420, carbon tetrachloride 5311, nitrobenzene 8388, 9053, ethyl ether 13441, monochlorobenzene 9277, thionyl chloride 9744, aluminium alkyls 9785, hexane 10870, phosphorous trichloride 10920, acrylonitrile 11141, dinitrotoluene 12033, methyl bromide 12034, MEK 12141, trichloroethane 12142, tetrachloroethane 12143, asbestos 11451, hydrogen peroxide 14200, carcinogenic substances 14165.

Acetylene cylinders 8433, agitator equipment 9522, air pollution control - glossary 4167, limits 9005, methods of measurement of air pollution 5182 (Part I to 20), air pollution control in petroleum refineries 10179, gas cylinders 5845, 5903, 8451, colour code for gas cylinders 3933, for pipe lines 2379, electrical instruments for hazardous atmosphere 8945, (See Part 8 of Chapter-11 also), static electricity 7689, electro heat installations 9080, 9021, fluid flow meters 9115, venturi meters 4477, fire detectors 2189, 2175, fire extinguishers 2190, 5896 (See Part 2 & 3 of Chapter13 also), gas industry 7062, gas masks 8523, gas oven 7342, 4473, gas pressure pipes 8329, gas scrubber, cooler or absorber 9240, gases flammable classification 9570, gas detection 7577, 10386, gaseous emissions nitric acid 9005, sulphuric acid 8635, perchlorates of ammonium, potassium and sodium 13914, sulphur dioxide 13910, petroleum refineries 8636, process control valves 10187, manhole for chemical equipment 3133, measuring cylinders 878, solid mineral fuels 3810, testing atmospheric conditions 196, thermal insulating material 7240, 7413, thermocouple pyrometers 2053, vacuum-filters 6034, 5676, gauge 8276, pump 6849, technology 4110, 8245, valve-ball 9890 for LPG cylinders 8737, 8776, globe steel-10605, work environment monitoring code 9679, safety in microbiological laboratories 12035.

Guide for handling cases of pesticide poisoning 4015 (Part 1: First-aid measures. Part 2: Symptoms, diagnosis and treatment), packing 6604, code of safety for malathion 10872, zinc phosphide 9278, aluminium phosphide 9279.

LPG storage installations 6044 (Part I & 2), code of safety in electric and gas welding and cutting operations 818.

Unfired pressure vessels 2825, steel forging for fired and unfired pressure vessels 9683, glossary of terms relating to corrosion of metals 3531, cathodic protection of steel structures 8062 (Part I to 4), safety in compressed air 4138, steel plates for pressure vessels 2041, Non-destructive testing - magnetic particle 3415, 3703, 7743, 10724, 10543, radiography 2478, 2595, 2598, liquid penetrants 12889, concrete methods 13311, ultrasonic testing 2417, 9346, 11630, eddy current 12965.

Fire safety of buildings 3594, ventilation in petrochemical plants and refineries 12332, classification of flammable gases/vapours with air according to their maximum experimental safe gaps and minimum igniting currents 9570, maintenance and operation of petroleum storage tanks 9964 (Part I & 2), safety in electro-heat installations 9080 (Part I to 4), flash back arrestor (flame arrester) 11006, purchaser's data sheet for gas scrubber, cooler or absorber 9240, safety belt and harnesses 3521, breathing apparatus 10245 (Part I to 4).   .

Methods of sampling chemicals and chemical products 8883 (Part I & 2), methods of sampling and test for industrial effluents 2488 (Part I to 5), tolerance limits for industrial effluents CHD 12, or 2490 (Part I to 10), treatment and disposal of effluent? of cotton and synthetic textile industry 9508, liquid sedimentation methods for determination of particle size of powders 5282, solid.waste analysis 10158.

Plant layout, safe practice 8089, 8091, emergency showers and face mountains 10592, safety colours and signs 9457, accident prevention tags 8095, gas detector tubes 13293.

Code of Practice on Occupational Safety and Health Audit 14489.

OISD Standards:

Oil Industry Safety Directorate (OISD) has published the safety standards for oil refineries, LPG bottling plants, gas terminals, ONGC and GAIL installations etc. Some such standards are mentioned below:

OISD Standards:

OISD-106	Process design and operating philosophic on pressure relief and disposal system.
OISD-110	Recommended practices on static electricity
OISD-112	Safe handling of air-hydrocarbon mixture; and pyrophoric substances.
OISD-117	Fire protection facilities for petroleum depots and terminals.
OISD-118	Layouts for oil and gas installations.
OISD-119	Inspection of pumps. Inspection of compressors.
OISD-120	Inspection of turbines & diesel engines. Inspection of rotating equipment components.
OISD-121	Predictive maintenance practices. Inspection and maintenance of mechanical seals.
OISD-126	Specific maintenance practices for rotating equipment .
OISD-127	History recording of rotating equipment.
OISD-128	Inspection of unfired pressure vessels.
OISD-130	Inspection of pipes, -valves and fittings.
OISD-132	Inspection of pressure relieving devices.
OISD-137	Inspection of electrical equipment.
OISD-140	Inspection of jetty pipelines.
OISD-144	LPG bottling plant operations -
Vol. I	Design philosophies.
Vol. II	Operating practices
Vol. III	Inspection and maintenance practices
Vol. IV	Safety and fire protection
OISD-146	Preservation of idle electrical equipment.
OISD-147	Inspection and safe practices during electrical installations.
OISD-148	Inspection and safe practices during overhauling electrical equipment.
OISD-153	Maintenance & inspection of safety instrumentation in hydrocarbon industry.
OISD-154	Safety aspects in functional training.
OISD-156	Fire protection facilities for port oil terminals.
OISD-160	Protection of fittings mounted on existing LPG tank trucks.
OISD-161	Rescue and relief operation involving tank truck accident carrying LPG.
OISD-162	Safety in installation and maintenance of LPG cylinder manifold.
OISD-169	Small LPG bottling plants (Design and fire protection facilities).

See Chapters II, 13, 24 and 25 for relevant Indian Standards on the subjects of electricity, fire and explosion, industrial hygiene and health and personal protective equipment.

6 TYPES OF CHEMICAL HAZARDS AND CONTROLS

People working in chemical factories and dwelling nearby are exposed to various types of chemical hazards. Inflammable, explosive, toxic, corrosive, reactive, radio active, oxidising, reducing, decomposing, compatible and hidden hazardous nature of chemicals pose material or property hazards. In process, chemical and physical change, chemical reaction, pressure, temperature, level, flow, quantity and other parameters create process hazards. The vessels and equipment in which the chemicals are stored, handled or processed, pose vessel hazards. The inadequate,, defective, under-designed or wrongly modified control devices or failure thereof cause control hazards. Fire or explosion causes fire hazards. Effluent disposal and gaseous emissions bring pollution and toxic hazards. Leaks, spills and splashes cause handling hazards. Absence, non-use or failure of fire fighting equipment, personal protective equipment, emergency control devices reveal accident and emergency hazards. All other unsafe working conditions and unsafe actions pose a variety of hazards that all need to be prevented and controlled.

Many safety measures are available to deal with above hazards. Identification of contents, properties, hazards and quantity of chemicals, their content minimisation, proper storing, handling and packing; auto control, recording and warning devices for level, pressure, vacuum, temperature, flow, feed, speed, cooling, heating, stirring, discharge, contamination; remote control devices, proper ventilating, exhaust, scrubbing, neutralising, inactivating and incinerating devices; monitoring, measuring, recording, tripping, correcting and controlling system, fire fighting and personal protective equipment, emergency and disaster planning, controls and all engineering well designed process and plant layout and fully safe actions of workpeople are utmost necessary to fight these hazards and to control over them. Some types of hazards are as follows:

1 Health (Toxic) Hazards :

(a) Types of effects are -

Allergy, Irritation, Oxygen deficiency (asphyxiation). Systemic poisoning (eg damage to liver, kidney, CNS, reproductive system etc.). Cancer, Damage to unborne foetus (teratogenesis). Genetic effects on future generations (mutagenesis). Dust effect (pneumoniosis).

Some effects are acute (local or short term) and some are chronic (long term, delayed or after repeated exposures).

(b) Factors creating effects are -

Type of concentration of chemical. Combined effects of mixtures, Properties of the material including its toxicity. Work methods. Nature of exposure (short term, long term) Routes of entry (through nose, mouth or skin) and Individual susceptibility.

2 Fire and Explosion Hazards :

Heat generation due to chemical reaction, Open flame, Radiant heat. Friction, Spontaneous combustion. Electric current. Static electricity and Fuel or Solvents like Low flashpoint and Low boiling point liquids, Gases and Solids (dusts, powders, lumps, crystals)

3 Biological Hazards:

Biohazards refer to plants, insects, animal and human pathogens that pose a potential risk to the health of humans, animals and also to the environment. Their ill effect is the illness through infection or disruption of the environment. They can be unique to a specific occupation or may affect the general public as epidemic (e.g. cold virus) or spread from person to person like highly publicised AIDS.,

Occupational exposure is possible in bio-laboratory work, hospitals, nursing or medical research, farming, agriculture, slaughterhouses, meat cutting and packing etc.

Biological infections and parasitic diseases are caused by contact with domestic, laboratory and other animals. Occupations of such biohazards are : abattoirs, agriculture, animal attendants, bone and bone meal processing, butchers, dairy, forestry, hair, bristle processing, ivory horn processing, laboratory animals, hospitals, slaughter house, farms, gardens, chemical factories, meat packers, poultry, sewerage workers, stock farming, tanneries, veterinary work, wild life management, wood industry, transport and handling of animals etc. Disease-class wise worker groups are as under:

Bacterial Skin Infections	**Fungal Skin Infections**
Animal breeders Animal handlers Farmers Fishermen Food Processors Hide handlers	Bakers Bartenders Canny workers Cooks Dish-washers Domestic workers
Parasitic Skin Infections	**Viral Skin Infections**
Agriculture Grain handlers Harvesters Livestock workers Longshoremen Silo workers	Dairy workers Dentists Medical Practitioners Livestock handlers

Diseases caused by biological agents are : Anthrax Brucellosis, catarrh, erysipeloid, herpes virus infection infections, hepatitis, leishmaniasis, leptospirosis, lym-phocytic chorimeningitis, mice infection, Q fever, rabies (dog bite, hydrophobia), rat bite fever, ringworm, salmo-nellosis, toxoplasmosis, TB and asthma.

Biohazards can enter into body through inhalation, ingestion, injection or skin contact. The type and virulence of the organisms and the individual's body resistance can decide whether or not the person may contract the disease. If other chemical or physical hazards are combined in the environment, the combined effect can be enhanced. Thus other environmental stresses may cause additive or synergistic effect. Viral oncology (tumour) research can provide information on risk of cancer due to viruses.

Safety and Control Measures : These are necessary to prevent health effects of toxic, highly infectious or oncogenic bio-agents. A written control plan including instructions for awareness, emergency action, safe procedure for handling, first-aid and reporting is useful. Employees should be immunised by effective vaccine if available. Vaccination is effective against smallpox, tetanus, yellow fever, diphtheria and hepatitis B. Proper placement and medical surveillance are also important. Pre-placement medical examination can give a baseline reference. Work assignment records should be maintained.

Pregnant women working in oncogenic virus laboratories should be counselled at the earliest possible time. They should be transferred to a non-virological department if possible.

Good housekeeping, quick decontamination of place and equipment, sterilisation, cleaning by germicide, use of PPE, no eating, drinking, smoking etc. in work areas, display of biohazard symbol, animal care and handling, bio-safety cabinets (local exhaust ventilation), effective filtration of room-air, ultraviolet air locks and door barriers to separate areas of unequal bio-risks, change rooms, safety showers, effluent treatment etc., are important safety measures.

AIDS (Acquired Immune Deficiency Syndrome) caused by HIV (Human Immuno deficiency Virus) reduces body's ability to fight infections. Diagnosis of white blood cells (WBC), no sexual contact with AIDS partner, avoidance of intravenous drugs and. medical treatment are useful.

4. Atomic Radiation Hazards-

Radioactive substances and Radiation processes (X-ray, NDT, Nuclear power plant etc.) cause severe health hazards.

5. Preventive & Control Measures :

Six Basic Principles

1 Elimination of substance or process.
2 Substitution of safer alternative.
3 Distance, Guard, Enclosure, Isolation, Shielding or Segregation of hazardous process.
4 Ventilation, general & local exhaust.
5 Personal Protective Equipment.
6 Personal hygiene.

6. Emergency Control Procedures :

1. Speedy Leak & Spill Control procedures.
2. Emergency shut-down procedure.
3. On site emergency plan.
4. Off site emergency plan.
5. Mutual aid arrangement with neighbouring industries.
6. Retainership for help at the time of emergency.
7. Regular rehearsal of emergency procedures (drill), updating and reviewing of the plan.

7 MATERIAL (PROPERTY) HAZARDS AND CONTROL

Make a list of all raw materials, products, byproducts and intermediates. Identify them by their nature of hazard and risk potentials. Classify them as inflammable, explosive, toxic, corrosive, radioactive, reactive, oxidising, irritant, unstable, compressed gases, dust and others. Also note their hazardous properties viz. boiling point, flash point, LEL, UEL, LD, LC, TLV, MAC, IDLH, density, solubility etc., to understand the ill-effects of the chemical. Reference No. I to 4 given at the end of this chapter explain all such terms and give them for various chemicals. Reference No. II gives such hazardous properties of some selected chemicals.

The chemicals may cause either physical hazards or health hazards. The physical hazards are caused due to dust, corrosive, explosive, flammable and reactive chemicals, compressed gases and oxidisers. The health hazards are caused due to toxic, irritant and carcinogenic chemicals. Carcinogenic causes cancer. Mutagenic causes inherited changes and teratogenic causes harm to unborn. Micro-organisms and radioactive chemicals also cause health hazards' The hazards are also classified as first and second degree hazards. The first degree hazards are caused by corrosive, flammable, explosive, toxic and oxidising chemicals, heat or ignition source, human error and failure of equipment etc. The second degree hazards injure life and property and include fire, explosion, toxic exposure, corrosive chemicals, collision, slipping, falling etc.

7.1 Identification and Classification of Chemicals

Identification of chemicals begins with the knowledge of basic chemistry. Refer Table No. I in Chapter 32 to identify first some commonly used elements and radicals. This will help to identify the chemicals.

Chemicals are classified in different ways. For study (chemistry) point of view, they are broadly classified as inorganic and organic chemicals. Inorganic chemicals are sub-classified as metals and non-metals. Out of 104 elements, 80 are metals and majority of them (except mercury) are solids, shining, reflecting, good conductor and forming reducing agents and basic hydroxides. In non-metals, more than half are gases and remaining are hard solid, non-shining, less reflective, bad conductor and forming oxidising agent and acidic hydroxides. Some examples are given below:

Metals: Aluminium, Arsenic, Beryllium, Calcium, Chromium, Cobalt, Copper, Iron, Lead, Manganese,' Mercury, Nickel, Radium, Sodium, Tin, Uranium, Zinc etc.

Non-metals : Bromine, Chlorine, Fluorine, Iodine, Oxygen, Phosphorous, Sulphur etc.

Organic chemicals include carbon compounds. They are subclassified as under -

Aliphatic Compounds (without benzene-rings) : Hydrocarbons, Halogen derivatives of paraffin, Alcohol, Ethers, Aldehydes, Ketones, Carboxylic acids and their derivatives, organic compounds of Nitrogen and Sulphur,. Carbohydrates, Alicyclic compounds etc.

Aromatic Compounds (with benzene-rings) : Benzene and its derivatives. Aromatic amines, Diazo compounds. Dyes, Phenols, Aromatic alcohol. Aromatic aldehydes, Ketones and quinones and Aromatic carboxylic acids.

Heterocyclic Compounds and Polymers (with other-rings) : Furan, Pyrrole, Thiophene, Pyridine, Quinoline, Isoquinoline, Alkaloids-coniine, nicotine, Drugs, Hormones, Vitamins/Enzymes and Polymers Natural and Synthetic Rubber like neoprene, butadiene; synthetic fibres like nylon, orlon, vinyon, terylene, Synthetic plastics and resins like cellulose, formaldehyde, alkyd, vinyl, acrylate and polystyrene resins and silicones.

Chemicals are also classified as under :

1. **According to their Physical State** i.e. solid, liquid or gases. Fine particles of solid like powder, dust, fumes and smoke are called particulate matter. Their suspension in air or gas also exists. Liquids are classified as acid; alkali, solvent, suspension, liquid mixture, aerosols etc. Gases are classified as inert (N21 C02), reactive, toxic, irritant, corrosive etc.
2. **Noxious Gases :**
   (1) Irritant gases – Cl_2, NH_3, SO_2, NO_2, $COCL_2$, Aldehydes etc.
   (2) Systemic poisons – C_6H_6, CS_2, PH_3, Stibine, Mn, Nickel carbonyl, Arsine, Halogenated hydrocarbons etc.
   (3) Simple asphyxiants – N_2, CH_4, CO_2 etc.
   (4) Chemical asphyxiants - CO, H_2S, HCN etc.
3. **Dust (Particulate Matter):**

(1) Causing plenumoconioses - Coal, Silica, Asbestos etc.
(2) Causing Asthma - Cotton, Flour, TDI etc.
(3) Causing allergy - fungal spores, bird fanciers, lung, bagassation etc.
(4) Causing lung cancer - Chromium, Asbestos, Benzene etc.

4. Biological Agents and Diseases :

(1) Virus Rickettisia - Psittacosis, rabbis etc.
(2) Bacteria - Anthrax, Woolsorter's disease, Leptospirosis or Weal's disease, Brucellosis, Tetanus etc.
(3) Fungi - Ringworm, Moniliasis etc.
(4) Parasites - Hookworm
(5) Plant products - Dermatitis due to mango tree and cashew seed processing.

For details see the Schedule given under the Rules for manufacture, use, import, export and storage of hazardous micro-organism, genetically engineered organism or cells (Refer Part 10.9 of Chapter-28).

Some physical, chemical or biological agents cause skin diseases (dermatitis) and alcoholism, sickness or accident may also cause health effects.

The chemicals should be properly identified, classified and handled accordingly. Labelling on packages and containers is a basic requirement. For this purpose some major divisions are given below :

Corrosive Chemicals : Amyl trichlorosilane, Anisoyl chloride. Antimony pentachloride. Antimony pentafluoride, Benzoyl chloride. Benzyl bromide, Benzyl chloride. Benzyl chloroformate. Boron trichloride. Bromine, Bromine pentafluoride. Bromine trifluoride. Caustic potash. Caustic soda, Chloroacetyl chloride. Chlorine trifluoride, Chlorosulphonic acid, Chromic acid solution, Diethyl dichlorosilane. Ethyl chloroformate. Formic acid. Fluorine, Hexafluorophosphoric acid, Hydrazine, Hydrobromic acid. Hydrochloric acid. Hydrofluoric acid. Methyl chloroformate. Nitric acid. Perchloric acid, Oxybromide, Oxychloride, Tribromide, Trichloride of phosphorous, Tetrachloride, Sodium aluminats. Spent sulphuric acid, Sulphur chloride (mono and di). Sulphuric chloride, Thionyl chloride. Titanium tetrachloride. Phenol etc.

Oxidising Agent : Aluminium nitrate. Ammonium nitrate. Ammonium perchlorate. Ammonium permanganate. Barium chlorate. Barium nitrate. Barium perchlorate. Barium peroxide, Benzoyl peroxide. Nitrate peroxide. Permanganate of calcium. Chlorate and Magnesium chloride mixture. Chlorate of potash and soda. Chromic acid. Dimethyl hexane. Lead nitrate, Lithium peroxide, nitrate, perchlorate. Peroxide of magnesium. Potash permanganate. Permanganate of soda. Potassium bromate, nitrate, nitrite, perchlorate, permanganate and peroxide. Silver nitrate, chlorate, chlorite, permanganate, peroxide, and nitrite. Zinc ammonium nitrite. Zinc chlorate. Zinc permanganate, Zinc peroxide etc.

Carcinogens : Asbestos, Acrolein, Aniline, Acrylo-nitrile, Alpha- Naphthylamine, BetaNaphthylamine, Benzidine, Benzene, Benzyl chloride, Carbon tetrachloride. Chloroform, Chloropropane, Dioxin, Epichlorohydrin, Ethylene oxide, Formaldehyde, Perchloroethylene, Beta propiolacetone, Styrene, Tetrachloro ethane, Toluidine (ortho-meta), Toluenediamine, Trichloroethane, Trichloroethylene, Vinyl chloride, Pyridine, Phenol, 4-aminodiphenyl, Nnitrodiphenyl etc.

Poisonous Chemicals : Aldrin mixture. Aniline, Arsenate of lead. Arsenic acid. Bromide, Chloride, Sulphide of arsenic. Calcium arsenate. Phenol, Dinitrochlorobenzol, Cyanide of potassium and sodium, Cyanogen gas, Cyclohexane, Dinitrophenol, Ethyidichloroarsine, Hexaethyl tetraphosphate, Hydrocyanic acid and its fumes, Mercuric acetate, Marcuric ammonium chloride and benzoate, Mercuric cyanide, bromide, oxide. Iodide, Methyl bromide. Methyl dichloroarsine. Mustard gas. Nickel cyanide, Nitrobenzol, Nitrogen peroxide. Phosgene, Thio phosgene. Zinc arsenate, MIC (methyl iso-cyanate), Carbon monoxide. Cadmium, DDT, Methanoi, Phosphine and dangerous pesticides such as Parathion, Diazeomon, Tetraethyl pyrophosphate, Tetraethyl phosphate, Demeton, Scheadan, Methyl parathion, Cryolite, Pentachlorophenol. Dinitro-o-cresol, Endrin etc.

Pesticides - Insecticides:

Pesticides: Aluminium phosphide, aldrin, acephate, antu, Butachlor, Chlordane, Chlorpyrifos, Cycocel, Cypermethrin, DDT, Dimethoate, Decamethrin, DDVP, Dieldrin, Endosulfan, EDB, Formothion, Fenitrothion, Fenvalerate, Hexachlorobenzene (BHC), Heptachlor, Glyphosphate, Glyphosine, Malathion, Monocrotophos, Mercuric acetate, MEMC, 2,4-D Phosphomidone, parathion, Permethrin, Phenthoate, Phenyl Mercuric acetate, Quinalphos, Zinc phosphide etc.

Insecticides : Cupric sulfate, DDT, Leadarsenate, Liver of sulfur.

Fungicides : Bordeaux mixture, Chlornil, Chloropicrin, Cyprus oxide, Mercurous chloride, Pentachlorophenol.

Herbicides : Ammonium thiocynate NH,SCN
Vermicides: Anisole.

Explosive Chemicals : Amyl acetate. Carbon dust, Aluminium dust. Wood saw dust. Hydrogen, Sodium metal. Sodium nitrate. Potassium nitrate. Ammonium nitrate, Benzoyl chloride, Nitro glycerine. Phosphorous trichloride. Titanium powder, Hexane, Trinitro toluene, Carbon disulphide, Ethylene oxide. Cellulose films etc.

Solvents : Benzene, Acetone, Methanoi, Ethanol, Toluene, Carbon tetrachloride. Methyl chloride, Methylene chloride. Ethyl acetate. Ethyl ether. Methyl bromide, Nitro propane, Propyl acetate. Spirit, Petrol, Carbon disulphide. Ethyl benzene, Methyl-propyl, Turpentine, Chloroform, Aniline, Benzyl chloride, Bromobenzene, Chlorobenzene, Ethyl benzene, Ethylamine, Formic acid. Heptane, Glycerol, Iso Propyl acetate, Methoxy benzene (anisole), Methyloleat, Naphthalene, Nitrobenzene, Oleic acid. Phenol, Styrene, Vinyl acetate, Xylene, Ether etc.

Other Flammable Chemicals : Acetonitrile, Acrylonitrile, Aluminium triethyl, Amyl acetate, Amyl chloride, Amyl mercaptan, Amyl nitrate, Benzoyl peroxide. Butadiene, Calcium phosphide. Carbon disulphide. Carbon monoxide. Coal tar. Naphtha, Lacquer, Paint, Varnish, Diethyl aluminium chloride, Diethylamine, Dimethylamine, Ethyl aluminium dichloride. Ethyl chloride, Ethylene, Ethylene dichloride, Ethylene oxide. Ethyl nitrate. Ethyl nitrite, Heptane, Hexane, Iso octane. Liquefied Petroleum Gas (LPG), Lithium metal. Methane, Methyl acetone, Monoethylamine, Nickel carbonyl, Pentane, Petroleum naphtha. Phosphorous, Phosphorous anhydride, Photographic film. Sodium aluminium hydride. Sodium metal. Sodium methylate dry. Titanium metal powder, Vinyl chloride, Vmyl fluoride. X-ray film scrap etc.

Reactive Chemicals : Acetic acid. Acetone, Acetylene, Sodium, Potassium, Lithium, Magnesium, Calcium, Aluminium powder. Anhydrous ammonia, Ammonium nitrate. Aniline, Bromine, Chlorates, Chromic acid. Chromium trioxide. Chlorine, Fluorine, Hydrocarbons (Benzene, Butane, Propane, Turpentine etc.). Hydrocyanic acid. Hydrofluoric acid (HF), Hydrogen peroxide. Hydrogen sulfide. Iodine, Mercury, Nitric acid (Cone.), Oxalic acid. Peroxides, Phosphorous (white); Potassium chlorate. Potassium permanganate. Silver, Sodium, Sodium nitrite. Sodium peroxide. Sulphuric acid etc.

Alcohols : Allyl, ethyl, methyl, emyl, anisyl, benzyl, butyl, cetyl, citronellol, cyclohexanol, diols or glycols, lauryl, nerol etc.

Refrigerant Gases : Carbon dioxide CO, Ammonia NH, Freonetc.

Esters : Amyl acetate, arsenate, benzoate, borate, citrate, cynate, decanoate, glyceride, isocyanate, lipids, methacrylate, nitrite, oxalate, salicylate, stearate, succinate, sulfate, sulphonate, tertrate, thiocynate, thiosulphate, toluate, xanthates etc.

Ethers : Anisole (methyl phenyl ether), benzyl cellulose, thio ethers, RSR, vinyl ether etc.

Enzymes : Catalase, Deaminase, Dehydrogenase, Diastrate, Fermerit, hydrolases, lactose, oxidase, urease etc. Resins : Alkyd (glyptal), Allyl, Aminoplastic etc. Acids:

Inorganic : Hydrochloric, hydrobromic, hydrofluoric, hydroiodic, nitric, sulphuric, nitrous, sulphurous, sulphonic, chlorosulphonic, boracic or boric, phosphoric, phosphorous, perchloric, arachidic, arsenic, ascorbic, aspartic, aspirin, hydrazoic, behenic or docosanoic, bromic, chloric, chloroplatinic, chlorous, chromic, iodic, manganic, metaphosphoric, perboric, permanganate, persulphuric etc.

Organic : .Acetic, acrylic, adipic, amino or carboxylic, alginic, uric, uncleic, succinic, barbituric, benzenesulphonic, benzoic, capric or decanoic, hexanoic, caprylic or octanoic, carbolic or phenol, carbonic, carboxylic, caro's or persulphuric, ricinoleic, chloroacetic, cinnamic, citric, crotonic or butenoic, cyanic, cyanuric or tricyanic, ethylene di~minee tetraacetic acid (EDTA), fumaric, galic, gluconic, hexanoic, hydrodic, hydrobromic, hydrocyanic, hydrofluoric, hydrozy, hypoclorus, hypophosphorous, isophthalic, lactic, lauric, linolegic, meleic, malic, malonic, mandelic, methacrylic, molybdic, monobasic, necotinic, nucleic, octanoic, oleic, oleum, osmic, oxolic, oxydiacetic, oxydiethanoic, palmitic, pantothenic, pelargonic, phosphinic, phthalic, picric, pyrophosphoric, pyrosulphuric, pyruvic, racemic, ribonucleic, ricinoleic salicylic, sebacic, selenic, silicic, stannic, stearic, suberic, sulphanilic, fannic, tartaric, thiocyanic, thiosulphuric, tribasic, trihydroxybenzoic, uric, vanadic etc.

Compatible chemical means which can be stored or handled with that chemical to which it is compatible.

Incompatible chemical means which should not be stored or handled with that chemical to which it is incompatible. A list is given below :

Table 18.1 Examples of incompatible chemicals.

No.	Chemical	Incompatible Chemical
1	Ammonia (anhyd.)	Mercury, chlorine, calcium hypochlorite, iodine, bromine and hydrogen fluoride
2	Aniline	Nitric acid, hydrogen, peroxide
3	Bromine	Ammonia, acetylene, butadiene, butane and other petroleum gases, sodium carbide, turpentine, benzene and finely divided metals.
4	Chlorine	Ammonia, acetylene, butadiene, butane and other petroleum gases, hydrogen, Sodium carbide, turpentine, benzene and finely divided metals.
5	Copper	Acetylene, Hydrogen peroxide.

6	Hydrogen sulphide	Fuming Nitric acid, oxidising gases
7	Nitric acid (Conc.)	Acetic acid, acetone, alcohol, aniline, Chromic acid, Hydrocyanic acid, Hydrogen sulphide, flammable gases and nitratable substance.
8	Oxygen	Oils, grease, hydrogen, flammable liquids, solids or gases
9	Sulphuric acid	Chlorate, perchlorates, permanganates.

7.2 Material Safety Data Sheet (MSDS)

7.2.1 Format of MSDS :

For proper identification of material hazards a material safety data sheet should be prepared and supplied with each chemical so that its safety precautions .can be well understood. A specimen form is given below :

1. Chemical Identity:

1. Name of the Chemical
2. Formula
3. Synonyms
4. Trade name
5. Chemical Classification
6. Regulated identification
7. Shipping Name, Codes/Label
8. CAS No.
9. UN No.
10. ADR No.
11. Hazchem (EAC) No.
12. Hazardous Waste ID No.
13. Hazardous Ingredients and CAS No.

2. Physical & Chemical Data :

1. Appearance, State, Odour etc.
2. Specific gravity (Water = 1)
3. Vapour density (air = 1)
4. Boiling point
5. Melting/Freezing point
6. Vapour pressure
7. Solubility in water
8. Scrubbing/Neutralising/Inactivating media
9. pH
10. Others

3. Fire & Explosion Hazard Data :

1. Flash point
2. Autoignition Temperature
3. Flammable limits : LEL/.UEL
4. TDG Flammability
5. Explosion Sensitivity to Impact
6. Explosion Sensitivity to static electricity

7. Explosive material
8. Flammable material
9. Combustible and flammable Liquid
10. Pyrophoric material
11. Hazardous Combustion products
12. Hazardous Polymerisation
13. Corrosive material
14. Organic Peroxide
15. Oxidiser
16. Others

4. Reactivity Data:

1. Chemical stability
2. Incompatibility (Materials to avoid)
3. Reactivity
4. Hazardous reaction products

5. Health Hazard Data :

1. TLV (ACGIH)
2. STEL/SET
3. LC_{50} or LD_{50}
4. Odour threshold
5. Carcmogen ? Poison ? Liberates poisonous fume?
6. Routes of entry
7. Body parts that may be affected
8. Effects of exposure and symptoms
9. Emergency and first aid treatment
10. Engineering controls necessary for safe handling.
11. NFPA Hazard signals
12. Special Health hazards.

6. Preventive Measures:

1. Ventilation required and type
2. Personal protective equipment required and type
3. Handling and storage precautions

7. Emergency and First-aid Measure :

1. Steps to be taken in case material is released or spilled.
2. Waste disposal method for solid, liquid and gaseous waste.
3. Fire, extinguishing media, special procedures and Unusual hazards.
4. Exposure - First-aid measures. Antidotes, Dosages.

8. Additional Information / References

9. Manufacturer / Supplier's Data :

1. Name of Firm
2. Mailing address
3. Telephone/Telex/Fax Nos.
4. Telegraphic address
5. Contact person in emergency
6. Local bodies involved
7. Standard packing

8. Tremcard Details / Ref.
9. Other

10. Disclaimer:

7.2.1 Interpretation and use of MSDS

For the better understanding and use of the Material Safety Data Sheet, some terms are explained below:

1. Formula (Chemical) : It is a symbolic representation of a chemical entity or relationship between elements, molecule and atoms, e.g. H, one molecule of hydrogen, 2HSO two molecules of sulphuric acid, HO one molecule of water wherein there are two atoms of hydrogen and one atom of oxygen. CH benzene contains six atoms of carbons and six atoms of hydrogen in one molecule, group or ion. Thus by formula we can know the hazardous ingredient of a chemical.

2. Synonym : Indicates alternate name of a material. e.g. Dimethyl ketone or 2-Propanone for Acetone.

3. Trade Name : Commercial name of the product.

4. Chemical Classification : General classification is organic or inorganic. Hazardwise classification can be flammable, explosive, toxic or poisonous, corrosive, reactive, infectious, oxidising, radioactive etc.

5. CAS No. : It is Chemical Abstracts Service number to provide a single unique identifier with naming the chemical, e.g. CAS No. for acetic acid is 64-19-7. It does not indicate the hazards of a material.

6. UN No. : It is United Nations four digit number assigned to potentially hazardous material (e.g. Ammonia UN No. 1005) or Class of material (e.g. corrosive liquids UN No. 1760).

These numbers are internationally recognised and used by emergency response personnel (including ire fighters) to identify material during transport emergencies. UN, Hazchem, NA and PIN numbers have the same uses.

See also Part 14.2 (4).

7. Hazchem (EAC) - No. : Hazchem (hazardous chemical) Code or EAC (Emergency Action Code) is an emergency code confirmed by the Health & Safety Executive, UK. It consists of a number (I to 4) followed by one or two letters and signifies type of a fire extinguisher required, type of personal protective equipment required, whether the spillage should be contained or diluted with water, whether the material is reactive and whether evacuation of the surrounding area necessary. Hazchem No. of Sodium cyanide is 4X and that of Vinyl chloride is 2WE.

8. ADR No. : It is an Agreement concerning carriage of Dangerous goods by Road. This European agreement was arrived at Geneva by 19 European countries for the safety of international transport by road. It deals with the classification of hazardous substances, their packaging, loading and unloading, transportation and its equipment. It gives hazard identification numbers like UN hazard class number. Their comparison is given below.

Classification of Dangerous Goods by	
UN Number	**ADR Number**

1.	Explosives	2.	Emissions of gas due to pressure or due to chemical reaction.
2.	Gases-Compressed, liquefied, dissolved under pressure or deeply refrigerated.	3.	Flammability of liquids (vapours) and gases.
3.	Flammable liquids.	4.	Flammability of gases.
4.	Flammable solids.	5.	Oxidising (fire intensifying) effect.
5.	Oxidising substances or Organic Peroxides.	6.	Toxicity.
6.	Poisonous (Toxic) or Infectious substances.	8.	Corrosivity.
7.	Radioactive substances.	9.	Risk of spontaneous violent reaction.
8.	Corrosive substances.		
9.	Miscellaneous dangerous substances.		

Doubling (repeating) of an ADR digit indicates increase of that particular hazard. Prefix 'X' indicates that the substance can dangerously react with water. As an example ADR HIN (Hazard Identification No.) of Benzene is 33 (UN No. is 1114 and Hazchem No. is 3WE).

9. Appearance, State, Odour: Appearance includes colour. State means physical state - solid, liquid or gas. Odour indicates smell. Odour threshold is that minimum level (ppm) where the odour will start. If odour threshold is lower than the permissible safe limit (e.g. TLV, STEL, IDLH or LC), the odour indicates the presence of gas and some safety margin is available to run away or to take precautionary step. But if it is higher, the gas becomes toxic or hazardous before its odour starts and this condition is risky. In that event a reliable gas detector is useful. Sometimes odour is added to detect the gas leakage e.g. addition of mercaptan in domestic LPG. Ability to detect odour may vary from person to person and may mislead if the other odorous materials are simultaneously present.

10. Specific Gravity (water = 1) : It is the ratio of the density of a material to the density of water (which is I g/cc). Lighter material (Sp. gr. <l, e.g. benzene 0.88) will float and heavier material (Sp. gr. >l, e.g. sulphuric acid 1.84) will sink. This information is useful for spill or fire control.

11. Vapour Density (air = 1) : It is the vapour weight per unit volume. In MSDS it is given as the ratio of the density of a gas or vapour to the density of air. The air density is 1.293 gm/l, but here it is considered as 1 for easy comparison of gases. Lighter gases (Vd<l, e.g. ammonia 0.59) will go up (rise) in the air and heavier gases (Vd>l, e.g. chlorine 2.49) will come down on the bottom. This information is useful for ventilation design and evacuation (emergency) activity.

12. Boiling Point: It is that temperature at which the material changes from a liquid to a gas. Below this point the liquid can evaporate to form vapour but at the BP the change from liquid to vapour is faster. This increases the vapour concentration and its pressure. This condition poses higher risk of fire, explosion or toxicity.

13. Thermal Decomposition Products : If the material decomposes (breaks down) without boiling, the temperature at which it decomposes is given with the word "dec'. Some of the decomposition products are hazardous. The thermal decomposition products may be quite different from the chemicals formed by burning the same material (hazardous combustion products). Information regarding thermal decomposition is useful to design ventilation system where a material may be heated.

14. Hazardous Decomposition Products : They are formed when a material decomposes (without heating) because it is unstable or reacts with common material like water or air (oxygen). This information is useful to design storage and handling procedures. For example, phosgene decomposes into corrosive and toxic fumes of HCI and CO because of heating or coming into contact of water or steam. Here HCI and CO are hazardous decomposition products.

15. Hazardous Combustion Products : These are the chemicals which are formed when a material burns. They may be toxic, flammable, smoke, carbon particles or other hazards. Their amount varies according to temperature and oxygen (air) available. They may be different from the thermal decomposition products. This information is useful to decide the fire fighting material and procedure.

16. Melting Point : It is that temperature at which a solid material melts and becomes a liquid. This information is useful for storage and handling purpose. A melted material may distort a container.

17. Freezing Point : It is that temperature at which a liquid material freezes and becomes solid. This information is useful for storage and handling purpose. A frozen material may burst a container.

18. Vapour Pressure : It is .the pressure (mm of Hg) upon atmosphere of the vapour of a material at a fixed temperature (e.g. 20 °C). Higher vapour pressure indicates higher concentration and therefore higher hazard due to fire or inhalation.

19. Solubility : It is the ability of a material to dissolve in water or another liquid (solvent). It may be expressed as a ratio or described by words like insoluble, very soluble, sparingly soluble or miscible. This information is useful to decide a scrubbing media, spill control or fire fighting material and procedure. Such solvent should not be hazardous.

20. Scrubbing neutralising or inactivating media : These are those materials (liquids) which dissolve or react with the hazardous material (gas, liquid or solid) to diminish its hazardous exposure e.g. caustic, lime, water etc. If this is not possible, proper absorbent may be used e.g. sand, sponge rubber etc.

See Table 18.4 of this Chapter and Table-17 of Chapter-32 for scrubbers.

21. pH : It is a measure of the acidity or alkalinity (basicity) of a material when dissolved in water. It is expressed in a scale from 0 to 14 as under :

0-2	Strong acidic
0-5	Weak acidic
0-8	Neutral
9-11	Weak basic
12-14	Strong basic

This information is useful to select a neutralising material for scrubbing or effluent treatment or spill control.

22. Flash Point : It is the lowest temperature at which a material gives off enough vapour near its surface to form a flammable air vapour (gas) mixture so that it can be ignited if a spark is available. The lower flesh point indicates higher hazard as it can cause fire at a lower temperature. It is expressed as Closed Cup (CC) or Open Cup (OC). CC value is slightly less than the OC value.

23. Auto-ignition Temperature : It is the lowest temperature at which a material begins to burn in air without any contact of spark or flame. During heating if the material decomposes, the decomposed chemical may auto-ignite at some other temperature. Different test methods give different auto-ignition temperatures for the same material. Therefore this value is an estimate. The material should be stored, processed or handled well below its auto-ignition temperature to avoid the risk of self fire or explosion.

Substances liable to spontaneous combustion are those liable to spontaneous heating under normal conditions or to heating up on contact with air and being then liable to catch fire'.

24. Flammable or Explosive Limits (LEI/UEL) : The lowest concentration (percentage in air) of gas or vapour which will burn or explode if ignited, is called the Lower Explosive (or Flammable) Limit i.e. LEL or LFL. The upper concentration (percentage in air) of gas or vapour which will burn or explode if ignited, is called the Upper Explosive (or Flammable) Limit i.e. UEL or UFL. The range between LEL and UEL is called the Explosive (or Flammable) Range. The fire or explosion risk lies within this range but not out of it. Below LEL the gas-air mixture is too lean to ignite and above UEL it is too rich to ignite.

However the concentration above UEL should be considered dangerous as due to entrainment of fresh air, it may be diluted and enter the explosive range. Similarly after LEL if gas discharge is continued in the same air, it can also enter the explosive range. Thus explosive range can be reached depending on flow of gas and air affecting their concentration. Air and gas temperature may also affect Therefore the range should be considered as approximate values. For gas/vapour it is expressed in % of air (1% = 10,000 ppm) and for powder in gm/m3 of air.

This information is useful to avoid the conditions leading to the explosive range and to ascertain it before allowing any person to enter any vessel or confined space where such air-gas mixture is suspected. Explosimeters are available to detect this range. Detection should be of percentage of LEL and all safety devices (alarms, controls, trips etc.) should operate well below the LEL. Fire hazard should be prevented at predetermined percentage of LEL.

25. TDG Flammability : Transport of Dangerous Goods (TDG) classifies the materials according to their flammability as under

- 2.1 Flammable gas.
- 3 Flammable liquid (Subclasses 3.1, 3.2 and 3.3 based on flash point).
- 4.1 Flammable solid.
- 4.2 Spontaneously combustible material.
- 4.3 Material which gives off a flammable gas on contact with water.

26. Explosion Data (Sensitivity) : It gives explosive properties of a material e.g. low, moderate or high. It gives two types of sensitivity :

Explosion Sensitivity to Impact - It indicates whether or not the material will burn or explode on shock or friction, and

Explosion Sensitivity to Static Electricity - It indicates how readily the material can be ignited by an electric spark or static discharge.

27. Explosive Material : An explosive material is that material which can explode on impact or by electric spark. Schedule-1 of Manufacture, Storage and Import of Hazardous Chemicals Rules, 1989 defines 'Explosives' as those chemicals which explode under the effect of flame, heat or photo-chemical conditions or which are more sensitive to shocks or friction than dinitrobenzene (old definition) or pyrotechnic substance (firework) or which is capable of producing gas at such temperature, pressure and speed to cause damage to surroundings or exothermic reaction by heat, light, sound, gas, smoke or their combination (new definition).

28. Combustible and Flammable Material : Flammable solid, liquid or gas which can catch fire and burn rapidly or explosively are flammable materials.

The terms combustible and flammable both indicates the ability of a material to burn. Any material that will burn at any temperature is combustible by definition. Flammable are a special group of combustible materials that ignite easily and burn rapidly. For example, NaCI, CC_4 and CO_2 are non-combustible while sugar, cellulose and ammonia are combustible but non-flammable.

The more readily ignition occurs, the more flammable the material, less easily ignited materials are said to be combustible, but the line of demarcation is difficult to decide.

Normally combustible liquids are classified as those whose flash point is greater than 37.7°C (100 °F).

Flammable or Inflammable liquids are classified under MSIHC Rules as (1) Flammable gases (LEL upto 13% or explosive range 12%). (2) Extremely flammable liquids (FP<23 °C, BP<35 °C). (3) Very highly flammable liquids (FP<23 °C, BP>35 °C). (4) Highly flammable liquids (FP between 23 °C to 60 °C) and (5) Flammable liquids (FP between 60 °C to 90 °C).

Flammable liquids are extremely hazardous, as they give off vapours at low temperature and these vapours by travelling to a source of ignition can cause flash back to the flammable liquid. It is difficult to extinguish a burning flammable liquid with water because water may not be able to cool the liquid below its flash point.

Flammable gases (normally boiling point < 20 °C) are equally hazardous as flammable vapours as explained above. Confined flammable gases are most dangerous. Flammable gases are also defined as those which at 20°C and at standard pressure of 101.3 KPa, have LEL 13% or less or a flammable range of 12% or more regardless of the LEL.

Flammable solids can be ignited due to external heat, flame, process heating by interaction with water or other substances. Flammable solids are of various types (1) Dusts or fine powders e.g. cellulose, flour etc. (2) Spontaneously ignitable at low temperature e.g. yellow phosphorous (3) Those in which internal heat is built-up by microbial or other degradation activity e.g. fish meal, wet cellulosic material (4) Films, fibres and fabrics of low-ignition point materials.

Flammable solids are readily combustible or may cause or contribute to fire through friction or which are liable to undergo a strong exothermic reaction.

29. Corrosive Material : It can attack (corrode) metals or human tissues such as skin or eyes. Structure or metal container may become weak and eventually collapse or leak. Skin, eyes or other body parts can be badly affected (burning) by corrosive materials. Acids, halogen gases, chlorides, caustic, phenol etc. are corrosive.

30. Hazardous Polymerisation : A polymer is a natural or man-made material formed by combining units called monomers, into long chains, e.g. styrene is the monomer for polystyrene.

Polymerisation is the process of forming a polymer by combining monomers into long chains. Uncontrolled polymerisation can be hazardous, as it can cause heat, pressure or explosion. Some chemicals can polymerise on their own without warming, others upon contact with water, air or common chemicals. Vinyl chloride rapidly polymerises in presence of light, air or heat. Therefore polymerising conditions should be controlled properly, Inhibitors(negative catalysts or compounds that retard or stop an undesired chemical reaction such as polymerisation, oxidation, corrosion etc.) are normally added to products to reduce or eliminate the possibility of hazardous polymerisation.

31. Pyrophoric Material : Any liquid or solid that will ignite spontaneously in air at about 54.4 °C (130 °F). Titanium dichloride and phosphorous are examples of pyrophoric solids, tributylaluminium and related compounds are pyrophoric liquids. Sodium, butyllithium and lithium hydride are spontaneously flammable in moist air as they react exothermically with water. Such materials must be stored in inert gas or under kerosene. Some alloys (barium, misch metal) are called pyrophoric because they spark when slight friction is applied.

Pyrotechnic materials mean fireworks.

Catalysts of pyrophoric material which can burn in normal air, are replaced in the atmosphere of nitrogen blanketing. The workers have to wear self-breathing apparatus while doing such job, because in the atmosphere of about 90% nitrogen, oxygen is insufficient for breathing.

32. Oxidiser and Peroxide : It is a compound that spontaneously evolves oxygen either at room temperature or under slight heating. Oxidisers include peroxides, chlorates, perchlorates, nitrates and permanganates. These can react vigorously at ambient temperatures when stored near or in contact with reducing materials (that will remove oxygen or add hydrogen) such as cellulosic and other organic compounds. Storage areas should be well ventilated and kept as cool as possible.

Peroxides release atomic (nascent) oxygen readily. They pose fire hazards in contact with combustible materials, especially under high temperature conditions. They are used as oxidising agents, bleaching agents and initiators of polymerisation.

Oxidizing substances are not necessarily combustible in themselves but by giving oxygen they contribute to combustion of other materials.

Organic Peroxides contain bivalent 0-0 structure, are thermally unstable and may undergo exothermic self-accelerating decomposition.

33. Chemical Stability : A stable compound does not easily decompose or react readily. Chemical stability is the ability of a material to remain unchanged in the presence of heat, moisture or air. An unstable compound may decompose, polymerise, burner explode under normal environmental conditions. Special precautions are required to store or handle unstable materials. For examples, CS_2 decomposes in light and burns due to heat, spark, flame or friction and gives off toxic fumes of SOx. Caprolectum liberates NOx fumes due to heating. TNT explodes due to heavy shock or by heating. Thus conditions disturbing stability must be known.

34. Incompatibility : Compatibility means the ability of two or more materials to exist in close and permanent association indefinitely. Liquids and solids are compatible if the solid is soluble in the liquid. Water is compatible with alcohol (because it is miscible) but not with gasoline (e.g. petrol).

Incompatibility means disability to co-exist permanently. Therefore incompatible materials should not be stored or kept together. For example, toluene reacts violently with some acids, plastic or rubber, therefore, these substances should be kept away.

Incompatible materials can cause a fire, explosion, toxic release, violent reaction, polymerisation or destroy the structure or function of a product. This information is useful for storage and handling purposes.

35. Reactivity : Two or more chemicals can react with each other and give reaction products, e.g. $2H_2 + 0_2 = 2H_20$. A single chemical can react with air or water (which are also chemicals) and give the product, e.g. phosphorous burns in air and gives its oxides (P_2O_2 P_2O_5), sulphur burns and gives SO_2 etc.

Reactions are exothermic when they evolve heat and are endothermic when they need heat to maintain them. A reversible reaction is one in which the reaction product is unstable and goes back to the original substance spontaneously.

In MSDS we are concerned with the hazardous reaction or reactive material which can cause fire, explosion, toxic release or violent reaction with air, water or common chemicals or under environmental conditions. Phosphorous, CS, Sodium metal, acids (reactive with metals) etc. are known for their reactivity. This information is useful for storage, handling and process safety purposes.

36. Hazardous Reaction Products : These must be known for the safety of process, workers and environment. Here products are more important than the reaction because of their hazardous nature, e.g. Chlorine reacts with alcohol and forms explosive alkyl hypochlorite. If toxic fumes are to be generated, scrubbers are required, if flammable vapours are generated, inert gas blanketing is required and earthing of the vessel also becomes necessary. If reaction products are highly poisonous like NaCN, HCN etc., they are to be handled in a closed system.

37. Health Hazard Data : For TLV, STEL, IDLH, LD/LC etc. see Part 1.5.1, for routes of entry, see Part 1.5.3, for effects of exposure see Part 1.8.2, for engineering controls and Part 1.5.6 for health hazards, all of Chapter-24.

For emergency and first aid treatment and antidotes see Chapter-26, for fire and NFPA (National Fire Protection Association of USA) Code see Part 3.4 of Chapter-13, for ventilation see Chapter 10 and for personal protective equipment see Chapter-25.

TLV and STEL are given in 2nd Schedule of the Factories Act. LD_{50}, and LC_{50} are given in 1st Schedule of the MSIHC Rules for the purpose of major accident hazard. LD,, for insecticides are given in Rule 19 of the Insecticide Rules for labelling purpose. Lower these values, higher the toxicity. LD_{50} up to 200 mg/kg and LC_{50} up to 10 mg/l can cause major hazard. By local exhaust ventilation toxic gas, dust or vapour must be captured and effective PPE must be worn by the workers. Above STEL, SBA is desirable.

38. Tremcard : Transport Emergency Cards are to be given to the drivers carrying dangerous goods for emergency information which may be needed at any time during journey. The cards contain short information on nature of chemical, hazards involved, protective devices, emergency action for fire, spillage, leakage, first-aid etc.

See Part 6.2 of Chapter-28.

7.3 Safety Precautions, Supervision and Medical Examinations

A sample guideline is as under : The dangers of working with chemical substances can be reduced to a minimum by observing certain simple basic rules :

7.3.1 General Safety Precautions:

1. Gaseous, liquid or solid chemical substances whose properties are not fully known should be treated as dangerous and handled very carefully.
2. Avoid contact with chemical substances. Chemicals should always be handled mechanically or with protective equipment. Containers and implements which can be contaminated with chemicals should be handled wearing gloves. In special cases, additional protective measures will be utilised.

3. Cleanliness is a basic requirement for safe working with chemicals. Emission of dust, vapours and gases, and the spillage of liquids and solids can be largely eliminated by careful working. Local ventilation installations must be used. Implements should be cleaned immediately after use.
4. Chemical substances should always be used exactly according to the written procedure. Anyone deviating from the procedure on his own responsibility is a danger to himself and others.
5. Chemicals should only be used when the drums, sacks, containers or pipelines containing them are clearly labelled. Ensure that 'the product name and delivery number on the drums and on the delivery note coincide. Though appearance alone is no guarantee of correct identity, a visual check should be made. In case of doubt, or when a mixup has actually occurred, a report must be made immediately.
6. Many highly reactive chemicals may only be used under strictly controlled conditions. For substances which react violently with water, the water contact should be avoided.
7. Substances which decompose dangerously under the influence of air, elevated temperature, impact or pressure, or contact 'with catalysts, appropriate safety measures contained in the written procedure should be followed. Dry at low temperature. Release the vacuum in vacuum dryers with an inert gas instead of air. Do not open the drier before room temperature has been attained. Release the vacuum in vacuum distillations with an inert gas. Expose distillation residues to the air only when cold. Handle and store catalysts only under the specially defined conditions. Prevent compounds which are particularly prone to decomposition (e.g. certain diazo-compounds) from drying out (leaks, splashes).
8. Substances which ignite spontaneously e.g. white phosphorous, pyrophoric catalysts etc. should be handled under an inert gas or liquid. Where necessary wear special protective clothing. Keep the prescribed means of extinguishing on hand.
9. Prevent the possibility of dangerous combinations. Follow the written procedure precisely. When preparing work, ensure complete separation of compounds which are dangerous when mixed.
10. Not only actual explosives, but also numerous widely used chemicals can explode when exposed to catalysts, heat or impact. Examples : acetylene and derivatives, acetyl nitrate, acrylic acid and its esters, ethylene oxide, azides, azomethane, peroxides, chlorates, perchlorates, cyanogen chloride, hydrogen cyanide, hydrazine derivatives, ozonides, propargyl alcohol and other propargyl compounds, hydrogen azide etc. The handling of such compounds is governed by special safety measures, which are to be found in the written procedures.
11. Chemicals which are spilled or contaminated should not be simply discarded in the refuse bin, but disposed of according to instruction from the supervisor.
12. The quantities of chemicals stored in a chemical plant at any time should be kept to the minimum required for normal working.
13. Before starting any process, its raw materials, their properties (MSDS), chemical equation, its working temperature and pressure, flow or addition rate, type of vessel and its safety fittings, emergency controls, planning and procedure, evolution of any gas, complete reaction document, how it can go wrong and what could be its consequence, type of ventilation, electric fitting, personal protective equipment required, trips and alarms, safe close down procedure etc. must be known and studied.

7.3.2 Supervision by Qualified Supervisors

Under section 41C of the Factories Act, qualified supervisors are required to super-wise handling of hazardous substances. Rule 68-S of the Gujarat Factories Rules prescribes B.Sc or M.Sc with Chemistry or Diploma or Degree in Chemical Engg. with experience.

7.3.3 Medical Examinations and Health Records

Section 41B and C of the Factories Act, require medical examinations and health records of the workers engaged in hazardous processes. Rule 68-T of the Gujarat Factories Rules prescribed nre-employment and six monthly periodical medical examination. Form no. 32 for pre-employment and periodical examination and form no. 33 for fitness certificate are prescribed. Rule 102 states 27 schedules where at many places medical examinations of workers are prescribed. Looking to the hazards in chemical factories, such medical examinations are most necessary.

7.4 Information to workers and others :

Such information u/r 68K, GFR, requires :

1. Material Safety Data Sheet (MSDS) as per R68Q, in respect of every hazardous substance handled in the manufacture, transportation and storage in the factory. Their location and availability to the workers.
2. List of hazardous processes carried on in the factory.
3. Physical and health hazards arising from the exposure to or handling of substances.
4. Safety and control measures taken for above hazards.
5. Measures to be taken by the workers to ensure safe handling, storage and transportation of hazardous substances.
6. PPE to be used by the workers.
7. Meaning of labels and markings on the containers.
8. Signs and symptoms likely to be manifested on exposure to hazardous substances and to whom to report.
9. Measures to remove spillage or leakage of hazardous substances.
10. Role of the workers in the emergency plan and evacuation procedures.
11. Any other information necessary to ensure safety and health of workers.
12. Quantity of solid, liquid and gaseous wastes generated per day, their characteristics and methods of their treatment and disposal [S.41-B(3) &: R.68P].
13. On-site Emergency Plan and safety measures required to be taken [S.41-B(4)]. This requires a separate document.
14. Health Records should be made available to the workers [R.68R].

Such information shall be reviewed and revised by the occupiers to make them up-to-date [S.7A(3) & R.68M].

Above provisions create a need of SAFETY MANUAL so that such useful information for workers are properly documented and given to them for their daily use, emergency use and training. It is legally required to be furnished to the workers u/r 68K and to the Chief Inspector u/r 68L with any modification if necessary u/r 68M.

Thus Safety Manual becomes a basic (statutory) need for a hazardous factory.

Prepare your Manual to include all above information in details. Also include other information depending on the specific nature of your factory and necessary according to the expert's advice.

7.5 Hazard Communication System including Safety & Risk Phrases

Hazard communication system includes-

1. Qualitative description like health hazard, flammability hazard, reactivity hazard. Electrical hazard, machinery hazard, fall or slipping hazard elc.
2. Display of Hazard, Warning and Control indicating signs and posters as shown in figure 18.1. See Fig. 9.1 in Chapter-9 also.
3. Safe permissible limits of hazards like TLV, STEL, LD, LC, dBA etc.
4. Threshold quantities of hazardous chemicals as given in Manufacture, Storage and Important of Hazardous Chemicals Rules, 1989. (See part 10.8 of Chapter 28).

Fig. 18.1 Hazard, Warning and Control indicating Signs and Posters

5. CAS No., UN No., HAZ CHEM, DOT, SOLAS etc. (See Part 7.2.2 and Part 14.2-(4)).
6. Class label and Emergency Information Penal (See part 6.2 of Chapter 28).
7. TREM CARD (hazard information to be given to drivers of hazardous goods).
8. Index like DOW and MOND. (Energy hazard in facility)
9. Hazards prioritization by numbers as given by NFPA.
10. Safety and Risk Phrases.

Hazards prioritization given by NFPA is as under:

Health Hazards	H	= 0	Almost no health hazard
(based on TLV)		= l	Slight health hazard
		= 2	Moderate health hazard
		= 3	High health hazard
		= 4	Extreme health hazard
Flammability	F	= 0	Almost no flammability hazard
Hazard		= 1	Slight flammability hazard
(based on		= 2	Moderate flammability hazard
Flash Point)		= 3	High flammability hazard
		= 4	Extreme Flammability hazard
Reactivity Hazard	R	= 0	Almost no reactivity hazard
(based on Adiabatic		= 1	Slight reactivity hazard
Decomposition		= 2	Moderate reactivity hazard.
temperature)		= 3	High reactivity hazard.
		= 4	Extreme reactivity hazard.

Safety and Risk Phrases

Regulation 9 of the CHIP (Chemicals Hazards Information and Packaging) Regulation, 1993 gives requirements for the labeling of substances and preparations dangerous for supply. These include the name and address of the supplier, information about the substance, symbols and risk and safety phrases L 38 (Approved Guide to the Guidance and Labeling of Substances an(j Preparations Dangerous for Supply) gives guidelines particularly on: (1) the classification by physico-chemical properties, health effects and environmental effects; and (2) labeling by risk and safety phrases. These phrases are represented by number and .their specific meaning indicating type .of hazard in brief. Some phrases are represented by combined numbers.

Safety Phrases

S1	Keep locked up.
S1/2	Keep locked up and out of the reach of children.
S2	Keep out of the reach of children.
3/9/49	Keep only in original container in a cool, well-ventilated place.
S3/14	Keep in a cool place away from. (Incompatible materials to be specified by the manufacturer).
S 4	Keep away from living quarters.
S 5	Keep contents under ... (appropriate liquid to be specified by the manufacturer).
S 6	Keep under ... (inert gas to be specified by the manufacturer).

S 7	Keep container tightly closed.
S 7/8	Keep container tightly closed and dry.
S 7/9	Keep container tightly closed and in a well-ventilated place.
S 7/47	Keep container tightly closed and at a temperature not exceeding ... °C (to be specified by the manufacturer).
S 8	Keep container dry.
S 9	Keep container in a well-ventilated place.
S 10	--
S 11	--
S 12	Do not keep the container sealed.
S 13	Keep away from food, drink and animal feeding stuffs.
S 14	Keep away from ... (incompatible materials to be indicated by the manufacturer).
S 15	Keep away from heat.
S 16	Keep away from sources of ignition — No smoking.
S 17	Keep away from combustible material.
S 18	Handle and open container with care.
S 19	---
S 20	When using do not eat or drink.
S 20/21	When using do not eat, drink or smoke
S 21	When using do not smoke.
S 22	Do not breathe dust.
S 23	Do not breathe gas/fumes/vapour/spray (appropriate wording to be specified by the manufacturer).
S 24	Avoid contact with the skin.
S 24/25	Avoid contact with skin and eyes.
S 25	Avoid contact with eyes.
S 26	In case of contact with eyes, rinse immediately with plenty of water and seek medical advice.
S 27	Take off immediately all contaminated clothing.
S 27/28	After contact with skin, take off immediately all contaminated clothing, and wash immediately with plenty of ... (to be specified by the manufacturer).
S 28	After contact with skin, wash immediately with plenty of ... (to be specified by the manufacturer).
S 29	Do not empty into drains.
S 29/35	Do not empty into drains; dispose of this material and its container in a safe way.
S 29/56	Do not empty into drains, dispose of this material and its container at hazardous or special waste collection point.
S 30	Never add water to this product.
S 31	---
S 32	---
S 33	Take precautionary measures against static discharges.
S 34	Avoid shock and friction.
S 35	This material and its container must b disposed of in a safe way.
S 36	Wear suitable protective clothing.
S 36/37	Wear suitable protective clothing and gloves
S 36/37/39	Wear suitable protective clothing, glove and eye/face protection.
S 36/39	Wear suitable protective clothing and eye face protection.
S 37	Wear suitable gloves.
S 37/39	Wear suitable gloves and eye/face protection.
S 38	In case of insufficient ventilation, wear suitable respiratory equipment.
S 39	Wear eye/face protection.

S 40 To clean the floor and all objects contaminated by this material, use ... (to be specified by the manufacturer).
S 41 In case of fire and/or explosion do not breathe fumes.
S 42 During fumigation/spraying wear suitable respiratory equipment (appropriate wording to specified by the manufacturer).
S 43 In case of fire, use ... (indicate in the space the precise type of fire-fighting equipment If water increases the risk, add 'Never use water').
S 44 If you feel unwell, seek medical advice (show label where possible).
S 45 In case of accident or if you feel unwell, seek medical advice immediately (show tile label where possible).
S 46 If swallowed, seek medical advice immediately and show container or label.
S 47 Keep at temperature not exceeding ... °C (to be specified by the manufacturer).
S 47/49 Keep only in the original container at a temperature not exceeding ... °C (to be specified by the manufacturer).
S 48 Keep wet with ... (appropriate material to be specified by the manufacturer).
S 49 Keep only in the original container.
S 50 Do not mix with ... (to be specified by the manufacturer).
S 51 Use only in well-ventilated areas.
S 52 Not recommended for interior use on large surface areas.
S 53 Avoid exposure — obtain special instructions before use.
S 54 ---
S 55 ---
S 56 Dispose of this material and its container to hazardous or special waste collection point.
S57 Use appropriate container to avoid environmental contamination.
S58 ---
S59 Refer to manufacturer/supplier for information on recovery/ recycling.
S60 This material and its container must be disposed of as hazardous waste.
S61 Avoid release to the environment. Refer to special instructions/safety data sheets.
S 62 If swallowed, do not induce vomiting: seek medical advice immediately and show this container or label.
S 63 In case of accident by inhalation: remove casualty to fresh air and keep at rest.
S 64 If swallowed, rinse mouth with water (only if the person is conscious).

Risk Phrases

R 1 Explosive when dry.
R 2 Risk of explosion by shock, friction, fire or other sources of ignition.
R 3 Extreme risk of explosion by shock, friction, fire or other sources of ignition.
R 4 Forms very sensitive explosive metallic compounds.
R 5 Heating may cause an explosion.
R 6 Explosive with or without contact with air.
R 7 May cause fire.
R 8 Contact with combustible material may cause fire.
R 9 Explosive when mixed with combustible material.
R 10 Flammable.
R 11 Highly flammable.
R 12 Extremely flammable.
R 13 Extremely flammable liquefied gas.
R 14 Reacts violently with water.
R 14/15 Reacts violently with water, liberating extremely flammable gases.
R 15 Contact with water liberates extremely flammable gases.
R 15/29 Contact with water liberates toxic, extremely flammable gas.

R 16	Explosive when mixed with oxidizing substances.
R 17	Spontaneously flammable in air.
R 18	In use, may form flammable/explosive vapour air-mixture.
R 19	May form explosive peroxides.
R 20	Harmful by inhalation.
R 20/21	Harmful by inhalation and in contact with skin.
R 20/21/22	Harmful by inhalation, in contact with skin and if swallowed.
R 20/22	Harmful by inhalation and if swallowed.
R 21	Harmful in contact with skin.
R 21/22	Harmful in contact ith skin and if swallowed.
R 22	Harmful if swallowed.
R 23	Toxic by inhalation.
R 23/24	Toxic by inhalation and in. contact with skin.
R 23/24/25	Toxic by inhalation, in contact with skin and if swallowed.
R 23/25	Toxic by inhalation and if swallowed.
R 24	Toxic in contact with skin.
R 24/25	Toxic in contact with skin and if swallowed.
R 25	Toxic if swallowed.
R 26	Very toxic by inhalation.
R 26/27	Very toxic by inhalation and in contact with skin.
R 26/27/28	Very toxic by inhalation, in contact with skin and if swallowed.
R 29	Contact with water liberates toxic gas.
R 30	Can become highly flammable in use.
R 31	Contact with acids liberates toxic gas.
R 32	Contact with acids liberates very toxic gas.
R 33	Danger of cumulative effects.
R 34	Causes burns.
R 35	Causes severe burns.
R 36	Irritating to eyes.
R 36/37	Irritating to eyes and respiratory system.
R 36/37/38	Irritating to eyes, respiratory system and skin.
R 36/38	Irritating to eyes and skin.
R 37	Irritating to respiratory system.
R 37/38	Irritating to respiratory system and skin.
R 38	Irritating to skin.
R 39	Danger of very serious irreversible effects.
R 39/23	Toxic: danger of very serious irreversible effects through inhalation.
R 39/23/24	Toxic: danger of very serious irreversible effects through inhalation and in contact with skin.
R39/23/24/25	Toxic: danger of very serious irreversible effects through inhalation, in contact with skin and if swallowed.
R 39/23/25	Toxic: danger of very serious irreversible effects through inhalation and swallowed.
R 39/24	Toxic: danger of very serious irreversible effects in contact with skin.
R 39/24/25	Toxic: danger of very serious irreversible effects in contact with skin or swallowed.
R 39/25	Toxic: danger of very serious irreversible effects if swallowed.
R 39/26	Very toxic: danger of irreversible effects through inhalation.
R 39/26/27	Very toxic: danger of very serious irreversible effects through inhalation and in contact with skin.
R 39/26/27/28	Very toxic: danger of very serious irreversible effects through inhalation, in contact with skin and if swallowed.

R 39/26/28	Very toxic: danger of very serious irreversible effects through inhalation and if swallowed.
R 39/27	Very toxic: danger of very serious irreversible effects in contact with skin.
R 39/27/28	Very toxic: danger of very serious irreversible effects in contact with skin and if swallowed.
R 39/28	Very toxic: danger of very serious irreversible effects if swallowed.
R 40	Limited evidence of a carcinogenic effect.
R 40/20	Harmful: possible risk of irreversible effects through inhalation.
R 40/20/21	Harmful: possible risk of irreversible effects through inhalation and in contact with skin.
R 40/20/21/22	Harmful: possible risk of irreversible effects through inhalation, in contact with skin and if swallowed.
R 40/20/22	Harmful: possible risk of irreversible effects through inhalation and if swallowed.
R 40/21	Harmful: possible risk of irreversible effects in contact with skin.
R 40/21/22	Harmful: possible risk of irreversible effects in contact with skin and if swallowed.
R 40/22	Harmful: possible risk of irreversible effects if swallowed.
R 41	Risk of serious damage to eyes.
R 42	May cause sensitization by
R 42/43	May cause sensitization by inhalation and skin contact.
R 43	May cause sensitization by skin contact.
R 44	Risk of explosion if heated under confinement.
R 45	May cause cancer.
R 46	May cause heritable genetic damage.
R 47	May cause birth defects
R 48/20/21/22	Harmful: danger of serious damage to health by prolonged exposure through inhalation, in contact with skin and it swallowed.
R 48/20/22	Harmful: danger of serious damage to health by prolonged exposure through inhalation and if swallowed.
R 48/21	Harmful: danger of serious damage to health by prolonged exposure in contaci with skin.
R 48/21/22	Harmful: danger of serious damage to health by prolonged exposure in contad with skin and if swallowed.
R 48/22	Harmful: danger of serious damage to health by prolonged exposure if swallowed.
R 48./23	Toxic: danger of serious damage to health by prolonged exposure through inhalation.
R 48/23/24	Toxic: danger of serious datnage to health by prolonged exposure through inhalation and in contact with skin.
R48/23/24/25	Toxic: danger of serious damage to health by prolonged exposure through inhalation, in contact with skin and if swallowed.
R 48/23/25	Toxic: danger of serious damage to health by prolonged exposure through inhalation and if swallowed.
R 48/24	Toxic: danger of serious damage to health by prolonged exposure in contact with skin
R 48/24/25	Toxic: danger of serious damage to health by prolonged exposure in contact with skin and if swallowed.
R 48/25	Toxic: danger of serious damage to health by prolonged exposure if swallowed.
R 49	May cause cancer by inhalation.
R 50	Very toxic to aquatic organisms.
R 50/53	Very toxic to aquatic organisms, may cause long-term adverse effects in the aquatic environment.
R 51	Toxic to aquatic organisms.
R 51/53	Toxic to aquatic organisms, may cause long-term adverse effects in the aquatic environment.
R 52	Harmful to aquatic organisms.
R 52/53	Harmful to aquatic organisms, may cause long-term adverse effects in the aquatic environment.

R 53	May cause long-term adverse effects in the aquatic environment.
R 54	Toxic to flora.
R 55	Toxic to fauna.
R 56	Toxic to soil organisms.
R 57	Toxic to bees.
R 58	May cause long-term adverse effects in the environment.
R 59	Dangerous for the ozone layer.
R 60	May impair fertility.
R 61	May-cause harm to the unborn child.
R 62	Possible risk of impaired fertility.
R 63	Possible risk of harm to the unborn child.
R 64	May cause harm to breast-fed babies.
R 65	Harmful: may cause lung damage if swallowed.
R 66	Repeated exposure may cause skin dryness or cracking.
R 67	Vapours may cause drowsiness and dizziness.
R 68	Possible risks of irreversible effects.
R 68/20	Harmful: possible risk of irreversible effects through inhalation.
R 68/20/21	Harmful: possible risk of irreversible effects through inhalation and in contact with skin.
R 68/20/21/22	Harmful: possible risk of irreversible effects through inhalation, in contact with skin and if swallowed.
R 68/20/22	Harmful: possible risk of irreversible effects through inhalation and if swallowed.
R 68/21	Harmful: possible risk of irreversible effects in contact with skin.
R 68/21/22	Harmful: possible risk of irreversible effects in contact with skin and if swallowed.
R 68/22	Harmful: possible risk of irreversible effects if swallowed.

8 STORAGE HAZARDS AND CONTROLS

Mainly three types of vessels are used in industry. Storage vessels. Reaction vessels and Pressure vessels. Their safety aspect is discussed in brief below :

8.1 Material of Construction and Lining:

The first step toward controlling vessel hazards is the proper selection of construction of material for the vessel depending on the type of chemical to be stored or processed, chemistry of that chemical in relation to the material of vessel, type of use, durability required etc. Some information is given in Table 18.2 & 18.3.

Table 18.2 : Suitability of Materials

No.	Storage or Process	Suitable Material
1	Caustic Soda solution 50%	Monel (alloy of nickel and copper)
2	Brine (15% concentration)	-do-
3	Brine, saturated	Concrete tank
4	Chlorination of Benzene	Lead or glass
5	Polymerisation reactor to produce styrene butadiene rubber (SBR)	Stainless steel or glasslined vessel
6	Evaporator tubes for concentrating NaOH solution to 70%	Nickel
7	Caustic Soda (NaOH)	Steel, Nickel
8	Lining of rotary kiln in cement industry	High alumina and high mangesia

		bricks
9	Digestor of kraft paper mill	SS
10	Chlorine - Dry - Dry or wet	 Iron or steel, copper High silicon iron, silicon rubber, Kel-F and teflon
11	Urea autoclave	SS
12	Oleum	Steel tower
13	HCl - concentrated at 30°C	Teflon, Steel rubber lined PTEE and porcelin
14	HNO3 – aqueous -concentrated - concentrated at 100°C	SS Aluminium or Chroumium alloys (Cr> 18% for cold acid) High silicon iron, Kel-F
15	H_2SO_4 – to absorb SO_3 - pipes for 9% - pipe for dilute - upto 60°C	Packed steel tower lined with acid-proof bricks. Cast Iron Lead Lead lined vessel, Teflon, polythene
16	HCl absorber made of	Karbate
17	SO_3 absorber	Chemical stoneware
18	Ammonia - anyhdrous - liquid, shipment	 MS Steel container
19	Fruit juices, milk and milk products	Nickel
20	CCl_4	SS, tin, highs silicon iron (14% Si)
21	Alkaline solution	Nickel
22	Pressure vessel operating at 500 atm and 500°C	Mo9lybdenum SS
23	To pump caustic soda, chlorinated brine or hypochlorous acid	Rubber lined pumps
24	Rotary dryers	MS
25	Gobar gas plant - digester - gas holder	 Masonry wall MS
26	Coke oven - wall lining - regenerators	 Silica bricks Fire clay bricks
27	Fermentor to produce ethyl alcohol from molasses	Copper bearing steel
28	Reactor to produce PVC	Nickel or glass lined steel
29	Tubes for multiple effect evaporator for concentration of sugarcane juice.	Copper
30	Ceramic recuperators	Silicon carbide
31	Protection from rusting	G I Sheet
32	Fluorine, dry	Copper Vessel

Table 18.3 Non Suitability of Materials

No.	Storage or Process	Non Suitable Material

1	H2SO4 - 50 % concentration - 100% at 30°C	 Aluminium, MS, SS, tine, concrete Aluminium, tin, rubber
2	HCl 10% , Ferrous Sulphate, Aquaregia	Aluminium
3	HCl – concentrated	High Silicon cast iron (Si 14%)
4	WetSO_2	CI Vessel
5	H_2SO_4 – 95% or Ether	Silicon rubber
6	Fluorine, dry or wet	Glass
7	HCl, SO_2, Cl_2	Wood
8	Alkaline solutions	Centrifugal pump of pyrex or glass
9	HF aqueous at 100 °C	SS
10	Acetic Acid 40°C	Brass, Cl, MS, Tin
11	Atmospheric corrosion (slow oxidation)	Iron

Section 28 of Perry's Chemical engineer's Handbook (7th ed., 1997) is also useful for materials of construction.

8.2 Storage Vessels and their Safety Aspects:

Storage vessels are used to contain chemicals in bulk. Storage tanks to contain 10 tonnes to 10000 tonnes material arc constructed. Oil refineries, petrochemical plants or fertiliser plants have even bigger tanks also. If such tank leaks, breaks or caught in fire, a great hazard is possible. Bhopal tragedy was also arose from a storage tank of methyl isocyanate. When a fire, explosion or gas leak takes place from a bulk quantity, tremendous efforts are required to control the situation and save loss to people, property and environment. Therefore safety of storage tanks need; highest attention. Some main points are mentioned below -

The main types of storage are :

1. Liquid at atmospheric pressure and temperature (i.e. ambient condition).
2. Liquefied gas under pressure and atmosphere temperature.
3. Gas under pressure and
4. Refrigerated storage of liquids at low temperature (e.g. ammonia).

8.2.1 Safe Design and Maintenance :

After studying the properties of the material to be stored, proper selection of the material of construction, metal thickness, design, nozzles, connections, pipe lines, fittings, valves, pumps, lining, coating, jacketing, insulation, cladding etc. and colour coding are necessary. Table 18.4 gives some of such information:

Table 18.4 : Safety of Storage Tanks

No.	Chemical	Metal of the tank	Dyke / bund	Level gauge	Pressure & Temperature gauge	Safety Valve, Rupture Disc	Vent, Scrubber, Flare etc.	Transfer Pump
1	Sulphuric acid	MS	Yes	Float	No	No	Simple vent	Centrifugal

2	Hydrochloric acid	MSRL or FRP	``	``	``	``	Vent with water scrubber	``
3	Nitric acid 54% 98%	MS, Low carbon Aluminium	``	``	``	``	Simple vent	``
4	Alkali	MS	``	``	``	``	Simple vent	``
5	Oleum 23% 65%	MS	``	Dial meter	``	``	Vent in sulphuric acid tank	Submerisble or centrifugal
6	Formaldehyde 37%	MS	``	Float or Dial	Yes	Yes	Vent with water scrubber	Centrifugal
7	Ammonia (P 7 to 12 bar)	Steel (double wall for refrigerated storage)	``	Magnetic float, differential pressure, with alarm	``	Yes, double Safety Valve	Vent at height or water scrubber	Pressure
8	Chlorine (P 7 to 11 bar)	MS	``	``	Yes, double with high, low alarm	``	Vent with caustic or lime scrubber or flare	Dry air pressure
9	LPG (P 2 to 7 bar)	MS	``	``	Yes, double with high, low alarm	``	Vent with caustic or lime scrubber or flare	Dry air pressure
10	Flammable liquid / solvent	MS (SS for Methanol)	Yes	Close float or dial or DP	Yes if stored cold	Yes if inert blanketing	Vent with flame arrester or breather valve	Centrifugal

Outlet valve should be kept on side wall instead under the bottom to facilitate repairing and maintenance. Emergency bypass system should be kept ready.

To prevent escape of bulk storage remote operated isolation valve should be provided near outlet valve, drain point, filling point, pumps suction etc.

Non return valves (NRV) are useful to prevent reverse flow and excess flow valve (EFV) to prevent excess flow. If they are not fully reliable, shut off valves should be provided at critical service.

Tendency of purchasing second hand or old-repaired (fabricated with patchwork and welding) tank or vessel and to fit it to new requirement is an unsafe practice.

For corrosion prevention, tanks and pipelines should be coloured with anti-corrosive paints. Before painting, corroded portion should be tested and replaced. See Part 15.6 for details.

See Table 18.8 in Part 13.1(4) of this Chapter and Part 7.3.2 of Chapter-9 for colour coding of pipelines.

8.2.2 Notice of Identification :

A notice indicating the name of the chemical stored, tank capacity (tonnes or litres) and some important properties (e.g. Sp. gravity. Vapour density, Boiling point. Flesh point, LEL-UEL, TLV and Solubility) should be displayed on or near the tank. It should be clearly and easily visible and in the language understood by the workers.

8.2.3 Dyke or Bund :

This is required to restrict the spread of the leaking material, to safely contain within its periphery and to restrict the surface area of the leaking material in order to reduce its evaporation and for ease of fire fighting or other emergency control activity. The contained material can be safely disposed off or if it is burning, it can be extinguished easily by reaching up to dyke wall. If there is no dyke (or bund) the leaking material can come on the road or go in the plant and make more damage.

By partition walls in dyke, reactive chemicals or chemicals of different flash points can be kept segregated.

Dyke wall should be safe, sound and leak proof. Its floor should have a slope with a pit in corner to provide a discharge valve which should be opened only when the rain water or the stored (leaked) chemical is to be safely discharged. The volume of the dyke should be slightly more than the biggest tank inside. Wall height should be less than 2 mt (mostly 1 mt) for ease of fire fighting and maintenance work. Steps should be provided to go inside. Acid proof lining should be provided where required.

Dyke is always required if the liquid is stored at the atmospheric or low pressure and temperature. Refrigerated chemical when leaks, it remains liquid till it reaches its boiling point. Therefore dyke is required for it. e.g. refrigerated ammonia.

For highly volatile gases or gases at high pressure, dyke is not much useful and wire fencing is provided at a safe distance. For example, LPG, NGL, butane, butadiene, propane, ethane, methane, ethylene, ethylene oxide, hydrogen, acetaldehyde etc. are kept under vapour pressure where at the time of leakage, they spread rapidly and therefore their tanks are kept in open at a safe distance with fencing on four sides. The floor under such tank is given a slope so that dripping liquid may run away to avoid fire just underneath the tank.

While opening dyke discharge valve of a flammable material, spark should be avoided otherwise fire can travel inside the dyke and catch the tank.

Where possibility of explosion is there, impact or blast wall (thick, sound) should be provided near the tank.

8.2.4 Separation Distances :

Some recommendations are available to keep minimum safe distance, known as 'separation distance', between two tanks or between two groups of tanks or between a tank and a building or between a tank and a source of ignition. Based on radiant heat from the burning liquid or fire spread by vapour (VCE or BLEVE) such distances are prescribed. Normally a 15 m and 30 m distances are suggested. But based on the tank capacity this distance is variable. In a congested area, it is difficult to maintain such distance.

See Part 4.4 of Chapter-? for separation distances.

8.2.5 Vent Pipe :

While filling a tank air has to come out. A vent pipe at the top is required for this purpose. It is also useful to depressurise the vessel before opening it. Its diameter should be sufficient for easy escape of the air. Vent pipe may have a bend or roof to prevent outside thing (rain, bird etc.) going inside. Vent pipe should have wire mesh, flame arrester or breather valve if any flammable content is in the tank. They should be kept clean to avoid choking.

Normally flame arrester is suggested when the flash point of the content is below 23 °C. When explosive air mixture with vapour pressure is inside the tank, breather valve and flame arrester both are required. Flame arrester will disallow any spark to enter inside. The breather valve will inhale air when inside pressure will drop (due to vapour cooling) and exhale vapour when inside pressure will exceed the set pressure (due to pressure rising). Thus breather valve prevents continuous vapour discharge (evaporation) and loss of the content.

Vent with breather valve or safety valve is required when the boiling point of the content is below atmospheric temperature. When the content is flammable, nitrogen blanketing is necessary otherwise inhalation of the breather valve will take air inside which may form explosive air mixture. To avoid such situation, large diameter tank has a floating roof just floating on the surface of the liquid (flammable), thus disallowing any air gap.

Vent cooler (condenser cools the vent content and sends the liquid back to the vessel or receiver (e.g. methylene chloride).

Vent heater or pipe tracing (i.e. small diameter limpet steam pipe or coil is required to heat the content which can freeze on cooling (at ambient temperature) e.g. phthalic anhydride.

If the gas or vapour is toxic or corrosive, vent is connected with an appropriate scrubber, flare or incinerator.

If a flammable material is to be filled in a tank an inert gas (e.g. N,,) purging is required before filling the material and inert gas blanketing after filling the material.

Where there is a possibility of vent choking due to sublimation or polymerisation of the content inside, instead of vent pipe, safety valve or other device is necessary.

Where vacuum is required in the vessel, ventpipe is connected with a vacuum pump, ejector or a ventury system to provide suction. Such vapour being sucked is if toxic, it should be connected to a scrubber, if organic solvent, it should be connected with condenser and receiver and if flammable or/and toxic, it should be connected with flare or incinerator.

In transferring pressurised gases like chlorine, ammonia, LPG, open vent is not possible and it is connected as a return line in a closed circuit and the vent valve is closed after filling up the tank.

8.2.6 Overflow Pipe :

For the overfilling safety a safe overflow pipe is required. Its diameter should be slightly more than the inlet pipe diameter so that the overflow will be maintained if inlet flow is continued. If the diameter of the overflow pipe is smaller than that of the inlet pipe, continuing overflow may reach up to the top (may enter the vent) and damage the tank if the pressure is excessive. Connection of the overflow pipe should be 2 to 3 inch below the roof joint so that the material will come out (overflow) leaving some air space under the roof and the tank will never be subjected to the filling pressure. The overflow pipe should be extended unto bottom to disallow any free fall of the material and to discharge it in the dyke or any container safely.

If the liquid is fuming or contains less toxic or less flammable vapour it should have a valve or a bend with water sealing arrangement (if water is permissible) so that during normal condition vapour will not come out from the overflow pipe. The valve will be open only at the time of filling and closed when the filling is over. HCI vapour should be passed (scrubbed) in water and oleum vapour (SO) in sulphuric acid.

In process area, an overflow pipe of a measuring tank or day tank should be connected with a return line to the storage tank or some other container for safe discharge.

Tanks of pressurised gases or highly toxic or highly flammable material in bulk may not have overflow pipe. Instead, they will have high (safe) level alarm and feed pump trip device to stop the feed pump automatically at that level. Huge tanks (more than 1000 tonnes) have H (high) and HH (high-high) level alarms i.e. double alarms for double warning before reaching the highest level. Low level alarm is necessary where minimum level must be maintained. At that level the feed pump should automatically start.

The level alarm and feed-trip device (interlock) is a substitute of overflow pipe but if this device fails, an accident is possible. A simple overflow pipe is a safer engineering control. However the judgement depends on many other factors (e.g. type and quantity of material, storing parameters, flow, hazard, other safety, instrumentation and control etc.) and technical requirements.

8.2.7 Filling Ratio :

A tank should not be filled beyond its filling ratio (Rf) given as under -

$$C = \frac{D_{15} - Dr}{Dr\,(Tm-15)} \qquad Rf = \frac{95}{1 + C\,(Tm - Tf)}$$

Where
C = Coefficient of cubical expansion of liquid
D_{15} = Density of liquid at 15 °C
Dr = Density of liquid at Tm
Tm = Maximum bulk temperature °C
Tf = Filling temperature (mean) °C

Filling ratio or filling density is legally defined as the ratio of the weight of the material (liquid or gas) to the weight of the water that the tank will hold at 15 °C (See Part 3.5 of Chapter-28).

8.2.8 Level Indicator :

The quantity (measure) of the material in the tank should be externally visible so that its excessive (unsafe) filling can be avoided, minimum low level can be maintained and an order for next requirement can be placed.

An old manual method is to measure the level by a dip-rod (calibrated yardstick) inserting it from the top of the tank. This may be allowed for small or medium size tanks (upto 10 or 20 tonnes as in case of rail or road tankers). If the content is flammable, the rod should be non-metallic or it should pass through non-sparking lining of the hole (nozzle) to avoid spark while moving the rod. Dip rod system requires a worker to climb on the top of a tank and that is its disadvantage. But it gives correct measurement, not subjected to any instrumental error and that is its advantage. The Excise and Prohibition Department insists this dip-rod measurement probably due to this reason (they are more concerned with the excise duty i.e. money, connected with the quantity of a prohibited material).

From safety point of view, presence of a person on the top of a hazardous tank should be avoided. Now a days many types of level indicators are available. Simple glass tube (like water level gauges), float, magnetic, differential pressure, displacer, oscillator, electric, electronic and computerised control (from a control room) type direct reading level indicators are available in variety and they can be interlocked with other requirements also. They should be selected as per need depending on the type of content to be measured (e.g. sp. gravity, viscosity, colour, pressure, temperature, flow, fluctuations etc.) Like pressure and temperature indicator, reliability (quality) of a level indicator is equally important, otherwise it may lead to an error and accident. Therefore it should be ensured while purchasing.

8.2.9 Pressure Relief Devices :

If pressure inside a tank rises due to any reason, it may burst the tank from its weakest part or cause leakage from where it is possible. The content thus coming out is a material loss and in addition, it may create fire, explosion or toxic hazard. Therefore to avoid such situation a pressure relief device is necessary.

A safety valve is a common pressure relief device. It can be set to a predetermined (desired) pressure and when pressure exerted on it exceeds that pre-set value, it automatically opens and allows the pressure to release in the atmosphere or in a catch-pot or drowning tank if the content coming out is hot or hazardous. It automatically closes down also, after release of the excess pressure. Safety valves are of four types - spring loaded, weight lever, solenoid and pilot. Safety valves are used to release gas or vapour but not the liquid.

A Rupture Disc is required for the fast release or more flow from a bigger size hole or if internal pressure is too high or too rapid or the material is sticky and chokes the safety valve. This disc is selected based on many parameters (e.g. type of chemical, working pressure, temperature, reaction, material of the tank, viscosity, corrosivity, toxicity and flammability of the content etc.) One disc can be used for one pressure i.e. its set-pressure cannot be changed like safety valve, and after rupture the same disc cannot be reused. Once opened, it cannot reset at the lowered pressure like safety valve, and will allow the whole mass to come out till the hole is closed or the disc is replaced. This is its disadvantage. Therefore, it is inadvisable on tanks containing flammable gases or liquids. Rupture disc can be used in conjunction with a safety or relief valve. Then the disc will burst first without affecting the valve. If pressure is further built up, then the valve will open. Pressure gauge is provided between the disc and the valve to indicate that the disc has opened and what is the bursting pressure. Imperfections in manufacture, installation or caused by corrosion can result in premature failure of the disc. The rupture discs are used to release gas, vapour or liquid.

Relief valves do not full open at set pressure like safety valve, but open slightly and then open further as the pressure increases. They are of two types - spring loaded or power actuated by electric, air, steam or hydraulic power activated by a pressure sensor in upstream of the valve. Manually operated relief valves (like vent valve) are also possible but they are to be operated after seeing the pressure in the pressure gauge or after hearing an alarm. Relief valves are used for liquid discharge and not for gas or vapour.

Safety-relief valves can be used either as a safety valve or a relief valve, depending on the application. They are used for gas, vapour and liquids.

Fusible plug is a fitting filled with an alloy that melts at a predetermined temperature (not pressure) and gives way to the material to come out. Fusible plugs are used in boilers, domestic pressure cookers and compressed gas cylinders to prevent violent bursting. They are used for gas, vapour and liquids of high temperature.

Fire or Explosion Relief is provided by making the seam between the shell and the roof of the tank deliberately weak so that it may rupture first and the shell stays intact.

Vacuum breaker is also a type of pressure relief device and works like a spring loaded safety or relief valve but in the reversed direction. The outside atmospheric air pressure being higher than that inside the vessel, opens it to break the vacuum. This is required when the vacuum may increase to collapse the vessel. This device is used for air only.

Thus a relevant pressure relief device can be selected from above discussion. Double Safety Valves are required for bulk storage tanks of chlorine, ammonia, LPG, ethylene oxide etc., for the purpose of double safety. In that case there should be slight difference in their pressure settings so that functioning of both the valves can be verified by their one by one opening or no need arising to functioning by the second valve as the first opened safety valve works efficiently.

Where two or more safety valves are provided, their isolation valves are also provided to replace them while keeping at least one on the line. In such case, isolation valves on the line should be kept locked open' so that they cannot be closed unknowingly or without authority.

If addition is controlled, pressure can also be controlled. In nitration process addition of nitric acid should be at a slow or controlled rate, otherwise rapid pressure rise can burst the vessel. Safety valve may not be useful in that event. An efficient flow controller (automatic regulator) or an excess flow valve with a middle valve (for fine control) should be utilised in such condition, along with the pressure relief device.

It is better and safer to keep the pressure under control by controlling heat source, temperature or the rate of reaction.

8.2.10 Flameproof Fittings :

Electric fittings like motors, starters, switches, lamps, tubes etc., near the storage tanks containing flammable materials (see foregoing Part 7.2.1 for definition) should be of approved flameproof types and conforming to Indian Standards like 2148, 4691, 5571, 5780, 7693, 8239, 8240 etc.

Flameproof electric fitting is most essential if the material is having flash point less than 23 °C or if it is to be heated up to or above its boiling point, and also in case of solvent distillation. See Part 8 of Chapter II and Part 1.6 of Chapter 13. Other sources of ignition from welding, cutting, open flame, smoking, sparking, friction etc. should also be avoided.

8.2.11 Earthing & Bonding :

Tanks and piping containing flammable substance should have double earthings of appropriate type. Earthing pit should be recharged periodically for easy flow of the current. Resistance should be measured (below 10 K-ohm) and recorded. IS:3043 is useful for earthing code. Filling (inlet) pipe should be extended up to bottom or an inner limpet coil should be provided to avoid free fall and static charge due to material flow.

Pipe joints/flanges should have copper bonding to maintain electric continuity. Flange-guard is useful to divert the leakage downwards.

While loading or unloading flammable liquids or gases, the vehicle (road or rail tanker) should also be earthed during such operation.

8.2.12 Protective Media :

Low-boiling chemicals (e.g. Methyl bromide, ethylene oxide, ethylamine), toxic gases (e.g. chlorine, phosgene, HCN, NH,) or polymerising materials (e.g. MIC, styrene, acrylonitrile) should be kept below their boiling point/flash point. For this purpose either underground tank or insulation, or jacket and brine circulation, or refrigeration, or water showering etc. are employed. Brine and refrigerant gases are protective cooling media.

Chemicals of higher melting point (e.g. phthalic anhydride, dinitro benzene, naphthalene) are to be kept hot above their melting point for their easy- flow in liquid state. For this purpose steam jacket, limpet coil or tracings are used. Here steam is a protective heating medium.

Flammable chemicals or solvents of low boiling or flash points need inert gas blanketing (e.g. N , C0,,). For examples, acetaldehyde, acrylonitrile, benzene, EO, HS etc. need such inert gas blanketing to prevent spark contact and fire. When a safety or breather valve opens, first inert gas comes out and not the flammable vapour. Here inert gas is a protective medium.

Chemicals which catch fire in air (e.g. phosphorous, CS) are to be kept in water and chemicals which explode in water (e.g. sodium metal) are to be kept in kerosene and protected. Here water and kerosene are protective media.

Water curtains, sprinklers (spray nozzles) and remote operating valve are provided for chemicals like acetaldehyde, ammonia, HCN, where water can dissolve their vapour and keep the tank cool in case of fire. Water can also be used as a scrubbing medium for such water soluble gases.

Water sprinklers should work at a rate of 10 Lit/ m2/miri. Foam injection system (in atmospheric tanks) should work at a rate of 4.5 Lit/ 12/mn to extinguish the fire.

Thermal insulation (e.g. vermiculite cement of 2 inch thickness) for pressure storage and PUF insulation for refrigerated storage are also useful.

Thus selection and application of appropriate protective media for chemicals are always desired for safety of their storage or processes.

8.2.13 Personal Protective and Fire Fighting Equipment:

While working at storage, process, handling, use or transfer of chemicals, appropriate personal protective equipment (helmet, goggles, face shield, gloves, boots, apron, respirator etc.) should be worn by workers to protect themselves in case of any accidental discharge or exposure. Similarly a trained fire fighting team is also required to use appropriate fire fighting equipment. Training for use and maintenance of such equipment is most essential. See Chapters 25 and 13 for PPE and FFE.

8.2.14 Safe Loading / Unloading Procedure and Pump-transfer:

Liquid should be transferred by pump and not by any air pressure or truck-engine exhaust. Submersible pump at the top is more safe as it avoids the bottom valves and joints. Pressurised gases are transferred by their own pressure. Earthing of the tank, pump-motor and the truck-body are essential. Bonding on pipe-flanges are necessary. Flange-guards divert leakage downward.

8.2.15 Miscellaneous :

Storage safety is a wide subject and includes so many things. Despite above discussion a few things are to be mentioned. There should be minimum connections to a tank. Pipe joints should be safe and sound. Stiffeners and other supports should be properly provided. Staircase with handrail and working platform should be provided on the tank. For hazardous chemicals in bulk, the main outlet valve should be remotely controlled. Unloading bay should have ready connections with tank farm piping and fixed location for truck/tanker parking. Tanker carrying flammable material should have spark-arrester (muffler) over his exhaust pipe.

Dump vessel (one empty tank of the identical design to the storage tank) should be installed with ready connections to transfer the content in case of emergency. If possible, design should be to transfer by gravity.

Pump should be of proper design and capacity. Double mechanical seals should be provided to avoid gland leakage. Flange cap on flange-joint can divert the leakage downwards. Necessary drain and sample points should be provided.

In acids and alkali tank farm, acid proof lining/ flooring, water showers, cautionary notice, mechanical lifting device (e.g. trolley) and necessary PPE should be available. For spill control lime, sand, soda ash and ample water should be readily available.

Near tanks of toxic or flammable material, gas and flame detector with alarm, high pressure/temperature alarm, auto controllers, necessary scrubber or flare connections, FFE, PPE, good lighting and ventilation, safety showers, dyke, connections to ETP (Effluent Treatment Plant), emergency (alternate) power and water supply, emergency kit and tools, lightening conductor, wind sock, etc. should be provided as per requirement.

Modern sophisticated plants are run by latest control rooms where all process parameters are controlled and recorded from this control room. The latest instrumentation and computer control technology (e.g. DCS) is utilised.

See part 12 for instrumentation for safe plant operation.

8.3 Safe Storage and Handling of Flammable Liquids, Gases, Solids and Corrosive Chemicals

Storage tanks of dangerous chemicals must be constructed and controlled properly. Safe inventory must be maintained. Content should be minimum possible. Necessary safety fittings on the tanks should be provided. LPG tanks and tanks of other flammable or toxic chemicals must have proper safety devices. Toxic gases should be kept in liquefied state if possible. Cooling media and device, safety valves, pressure gauges, temperature-gauge, scrubber, level or content indicator, flare, water curtain, toxic exposure sensors and alarms, emergency bypass, safe discharge and collection, etc. should be provided as per requirement. Name and quantity must be clearly mentioned to assess the hazard potential. Barrels, carboys, glass vessels must be kept, handled and used in safe manners. Use emergency kits, tools etc. where necessary. All the vents of storage ranks of low boiling chemicals should be connected to an appropriate condenser or scrubber, Alternate power (e.g. 1x3 set) must be kept ready to run the cooling system, scrubber etc., in case the main power fails.

Safety measures of some specific chemicals arc stated below

8.3.1 Handling of Flammable Liquids

General guidelines for loading/unloading liquids

1. Take care of adverse weather conditions.
2. Safe access to the top of the trailer tank car.
3. Suitable fire extinguishers.
4. Where air pressure is needed or other gases such as nitrogen, adequate hose lines should be provided with reducing valves. Pressure should be as minimum as possible. Soundness of the pipe line and joints should be checked. Breakable pipes should not be used for toxic chemical.
5. Steam lines, if heating is necessary.
6. Personnel discharging duty should be in the vicinity.
7. Adequate personal protective equipment should be provided.
8. Emergency shower and eye washer should be provided.
9. Ensure that sufficient space is available in the receiving tank.
10. Training of personnel necessary.
11. Avoid mixing of chemicals. Take full precautions. .
12. Routine thorough check-up procedures.
13. Proper identification on discharge lines.
14. Earthing for transferring flammable liquids. Muffler on exhaust pipe.
15. Truck/tanker should be fixed by brakes or wheel-blocks and engine stopped while loading or unloading.

Flammable liquids are easily ignited and difficult to extinguish. Their vapours form explosive mixtures with air. Flammable liquids in unopened containers offer only moderate fire risk. They however, become severe fire hazard when containers are open or leaky. Before handling, containers should be carefully inspected and damaged or leaky containers, if any, be segregated. Containers should not be dropped, rolled or so handled as to risk damage to them.

Good housekeeping standards are-essential in storage areas. Such areas should be isolated by distance or constructions so that they do not expose important buildings to fire and in turn are protected from fire originating elsewhere. The extent of isolation depends upon the factors such as the maximum quantity of flammable liquid may be stored, the severity of the fire hazard presented by the flammable liquid etc. Detached locations should be preferred. Best locations are in the open under non-combustible weather canopies with minimum wall enclosure or in one story buildings without basements. Where storage in detached locations is not possible and the use of main building is unavoidable, with liquids offering only fire hazard, a room cut off from the rest of the space by fire resistant walls may be used. Where both fire and explosion hazard may exist in a main building, storage room should be located at an outside wall , cut off from other spaces horizontally and vertically with fire and pressure resisting construction. Floors should be liquid tight with slight down gradient to permit drainage. Rooms to bewell ventilated to safe guard against fire and explosion hazards as also against health hazards. Provision should be made for automatic sprinkler protection and all potential sources of ignition should be eliminated. Cutting and welding operation and smoking should be prohibited in storage area. The limitation regarding the maximum number of drums that may be stored in a particular location, the height of piles etc. would along other thing depends upon the severity of fire hazard associated with a particular flammable liquid.

8.3.2 Handling of Flammable Gases

Gases are generally contained in cylinders, in the compressed liquefied or dissolved state. Flammable gases will pose fire hazard when they leak or escape from their containers. Also when a gas is subjected to a high pressure, it could burst the container with serious consequences. In handling and storage it must be ensured that the cylinders are protected from damage or deterioration and heat. Some of the precautions to be taken are outlined below.

Cylinders should 'not be dropped, dragged, rolled on their side or permitted to strike one another or other surface violently. When removable caps are provided for valve protection, such caps should be in place at all times expect when cylinders are in use. It is safer to use suitable trucks to move them even through short distances. They must not be, lifted by their cap or with the aid of rope or chain slings. A safe cradle on platform with guard rails should be used for the purpose. Cylinders should not be used as rollers, or supports for any purpose other than to contain the contents as received.

Storage room for the cylinders should be dry, cool and well ventilated. Where practical, they should be of fire resistant construction. Highly flammable solvents, combustion waste materials, corrosives and cylinders of oxygen should not be stored near cylinders containing flammable gases. In outdoor locations they should be kept off the ground on a raised concrete pad or non-combustible rack and sheltered from sun by means of non- combustible canopy.

See also Part 8.6 following.

8.3.3 Handling of Flammable Solids

A large variety of solid materials used in industries and at other places present fire risk. Flammable solid materials become particularly hazardous under certain conditions. Some possess the ability of being easily ignited by external sources such as sparks and flame. Some other are liable to heat spontaneously and ignite. Certain materials have the property of releasing flammable gases when in contact with water. In the handling and storage of various flammable solids apart from taking normal precautions, additional precautions will have to be taken to guard against the hazard posed due to condition or circumstances under which flammable materials may became severe fire risk.

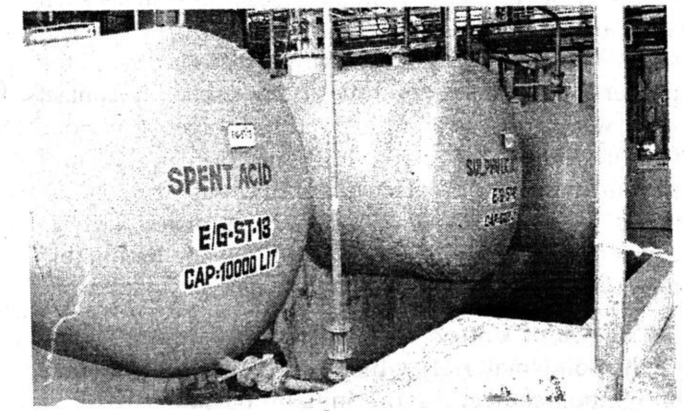
Bales of Cotton and Jute hemp represent some of the solid materials which are easily ignited. With an ignition source, the fire initially flashes over fibres on the surface and then -travels at a slower rate between bales and into individual bales. Ignition source may be electricity, mechanical sparks, smoking, matches etc. Bales should be protected from such source. Electrical wiring in a warehouse for the bales should be installed in a rigid metal conduit for protection against mechanical damage. Spark producing electrical equipment including switches, fuses, circuit breakers should be in dust tight enclosures. Ware-house to be of non combustible construction with floors sloping to prevent accumulation of water. Piles sizes to be not too large and about 3m wide aisles space to be maintained between piles. With bales of jute, at least 1m wide space should be left along the walls and with bales of other fibres, at least 0.8m wide gap is to be left. The height of the pile should be limited taking into account the floor loading capacity and the weight of bales when soaked with water. In any case at least 1m head clearance is to be maintained between the top of the piles and the deflectors or sprinklers.

See Part 9 of Chapter-21 also.

Bituminous coal represents flammable solids liable to spontaneous combustion. It absorbs oxygen from the air and the absorption is more rapid when the coal if freshly mined or contains much fine dust. Moisture adds oxidation. Coal should not be stored in contact with sources of external heat or over trenches, manhole covers and similar surfaces which may allow movement of air through piles. In yards, piles height to be limited to 3m with low grade coal and 5m with best grade coal. Where bins are used for storage, these should be of non-combustible material with the structure roofed over to protect the coal from rain. The space above the coal should have adequate ventilation to prevent concentration of gases given off by the coal.

Calcium carbide and Alkali metals are some of the solids which when in contact with water liberate flammable gases. In some cases the gases released may be ignited from the heat of reaction. These materials are to be packed in air tight containers and stored in dry cool and well ventilated building of non-combustible or fire resistant construction. They should be separated from combustibles, oxidising agents and mineral acids.

8.3.4 Handling of Corrosive Chemicals



Corrosive chemical will cause severe damage when in contact with living tissue or, in case of leakage, ill materially damage or even destroy the surrounding they come in contact with. It is likely to cause a fire when in contact with organic matter or certain chemicals. Certain corrosive substances have other more serious hazardous properties (toxicity, flammability etc.) and are commonly classed as toxic or flammable etc. rather then as corrosive.

Important corrosive substances are : Acids and anhydrous alkalis, halogens and halogen salts, organic halides, organic acid halides, esters and salts.

When in contact with human tissues, most corrosive substances will produce chemical burns, while certain other substances (as Chromic acid) produce deep ulceration. Many corrosive substances have a defeating action on the skin and may cause dermatitis.

The safeguards against these hazards are :

1. Preventing or minimising contact between corrosive substances and skin, mucous membranes and eyes.

2. Corrosive substances should not be allowed to come in contact with materials that may react.

3. All the containers, pipes, apparatus, installations and structures used for the manufacture, storage, transport or use of these substances may be protected by suitable coatings, impervious to and unaffected by corrosives.

4. All containers or receptacles should be clearly labelled to indicate their contents and should bear the danger symbol for corrosives.

5. A high standard of maintenance and good housekeeping is essential.

6. Adequate ventilation and exhaust arrangement whether general or local, should be provided whenever corrosive toxic gases or dust are present.

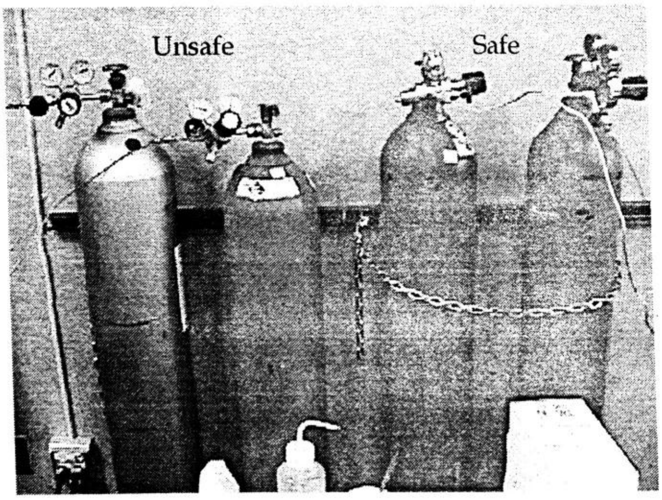
7. Personal protective devices should be used depending upon the nature of work viz. (a) Corrosion-resistant and impervious suits, or hand-gloves, aprons etc. (b) Respirator, gas mask or self contained breathing apparatus, (c) Barrier cream when exposure is not severe.

8. First aid treatment facilities should be provided and all concerned should be instructed to follow safe practices such as (a) Prolonged washing with water (b) Removing contaminated clothing (c) Seeking immediate medical help.

9. Safety showers and eye washers should be provided.

See also Schedule 12 and 19 under rule 102 of the Gujarat Fartnnp«i Rnips

8.4 Safe Storage & Handling of Gas Cylinders:



Cylinders should be tied by chain

In factories we find the use of gas cylinders of oxygen, nitrogen, acetylene, LPG, carbon dioxide, chlorine, sulphur dioxide etc. The gases are filled with pressure. Therefore when they leak, they come out with force and pose hazards of fire, explosion or toxicity. Therefore some rules are to be observed while handling them. They are stated below.

1. Following Indian Standards are useful for understanding design, construction, fittings, testing, safety devices, valves and use of gas cylinders:

IS	8198 (12 parts)	:	Code of practice for steel cylinders for different compressed gases.
IS	7241	:	Glossary of terms.
IS	5903	:	Safety devices.
IS	3224	:	Valve fittings.
IS	7202, 9199 & 9687	:	Threads of valves.
IS	4739	:	Identification of contents (Colour Code).
IS	6901	:	Pressure regulators for welding and cutting.
IS	8868	:	Periodical inspection.
IS	5845	:	Visual inspection for low pressure gas cylinders.
IS	8451	:	Visual inspection for high pressure gas cylinders.
IS	8433	:	Visual inspection for dissolved acetylene.
IS	3196 (3 parts)	:	For LPG, Steel cylinders for low pressure.
IS	8776	:	For LPG, valve fittings.
IS	8867	:	For LPG, vapour & test pressure.
IS	6044	:	For LPG cylinder installations.
IS	7680	:	For ammonia (anhy.) gas.
IS	7681	:	For chlorine gas.
IS	7312	:	For dissolved acetylene gas.
IS	7142	:	For low pressure liquefiable gas.
IS	7682	:	For methyl bromide gas.
IS	8016	:	Hand trolley for.
IS	5844	:	Hydrostatic stretch testing.
IS	3933, 3870 & 8382	:	For medical use.

2 Types of safety devices mentioned in IS 5903 are Bursting disc, fusible plug, PRV and their combination. It is prohibited to provide any safety devices on cylinders containing obnoxious or poisonous gases such as CO, HCI, HBr, HF, SO_2, CI_2, H_2S, town gas, Carbonyl chloride, Nitrosyl chloride, ,Nitrogen peroxide, Methylamine and Methyl bromide. Shut-off device (except built-in with safety device) is also prohibited.

Formulae for flow capacity of safety devices, identification and marking, number of test and test procedure and periodic inspection and maintenance are also specified in IS:5903.

3 Normal procedure to identify and classify (to put into a group) gas cylinders is to see their colours. See IS:4379 for this purpose. Commonly used cylinders are painted as under :

Acetylene	-	Maroon
Air, N_2	-	French grey.
Ammonia, CO_2, O_2, Phosgene	-	Black
Argon, HCN,	-	Peacock Blue.
Butane, Methane, Propane, LPG, CO, H_2, Coal gas	-	Signal red
Chlorine	-	Golden yellow
Ethylene, EO	-	Dark violet
Helium, Neon	-	Middle brown.

SO_2 - Light brunswick green.

Ground colour prescribed for flammable/ non-flammable and poisonous/ non-poisonous gas or mixture is white. Colour code is also prescribed for specific gas mixtures.

Thus specific colour indicates specific gas. Therefore die colour shall never be changed. If colour is washed out, rubbed or not clear, write the name of the gas on the cylinder or on a tag tied to it. In one factory, a worker joined an oxygen cylinder instead of nitrogen cylinder to a reaction vessel containing explosive mixture. It resulted into fire, explosion and death of another two workers. A mistake in handling can cause such serious accidents.

4. First verify the marking, number, company, pressure, weight, capacity and date on the cylinder before their use.
5. Cylinder should be handled in its special trolley or gently rolled on its bottom edge but not on the whole surface. It should not be thrown or .subjected to undue force for damage. Lifting machinery or magnet should not be used to lift them. While carrying a chlorine tunner (or any heavy cylinder) in a forklift, it should be tied with a chain to prevent rolling.
6. Long vertical cylinder should be kept upright in its stand or tied with chain to prevent falling.
7. No flammable material should be allowed nearby. Source of ignition, spark, flame, electricity, molten metal etc. must be kept away. Cylinder should not be used as earthing. It should be protected from excessive heat, cold, dampness and corrosive chemicals.
8. When not in use, the valve should be kept closed and covered with cap. If the valve is leaking, it should be repaired by an expert or trained man, otherwise the cylinder should be shifted in a remote open ground.
9. Pressure regulator (double regulators for pressure > 800 psi), pressure gauge and non-return valve (NRV) should be maintained in working order. Special spanner may be used to close or open the valve keeping the thread direction in mind. The spanner should be kept nearby.
10. Grease or lubricating oil should not be applied on valves of oxygen cylinders.
11. A store-room of gas cylinders should be well ventilated. Filled and empty cylinders should be kept separate. Construction should be fireproof if flammable cylinders are to be stored.
12. Before testing a cylinder, it should be carefully depressurised. Valves should not be interchanged
13. Pipelines connected with cylinder should be kept according to the pressure and type of gas. Flexible plastic pipe for toxic or highly flammable or explosive gas (e.g. Hydrogen) should be avoided or tightened properly and replaced in time. One worker died on the spot due to explosion when hydrogen leaked from the joint of a plastic pipe. Valve should be opened gently and only as per requirement.
14. Leakage of flammable gas may be checked by a soap solution and air bubble (not by naked flame or lighter), ammonia by sulphur dioxide and chlorine by ammonia water. Their bottles (torch) should be kept ready. No leakage should be checked by nose.
15. Quantity of cylinders should be restricted. If toxic and flammable cylinders are kept in the same shade, a partition wall should be provided. A blast wall is necessary for highly explosive cylinders. In a storage of flammable cylinders electric wiring/fitting should be flameproof and 'No Smoking' notice should be displayed. Earthing should be double and well maintained. Fire extinguishers, emergency kit and PPE should be kept ready. If the storage is in open land, a wire fencing and locked door should be provided.
16. Gas flow-rate may be known by providing flow meter or placing the cylinder on a weighing platform. Flow-rate should not be excessively increased.
17. The metal of adopter on a valve should be the same as that of the valve to prevent erosion of threads.

18. While connecting or changing a cylinder, necessary respirator and eye goggles shall be worn. First the cylinder valve shall be closed and then lhe process (header) valve. This will disallow any gas to remain in-between.
19. For emptying the residual gas, the cylinder shall not be heated. This needs a suitable vaporiser plant.
20. Provisions of Gas Cylinder Rules and SMPV Rules shall be followed. See Part 3.5 and 3.6 of Chapter-28.
    For chlorine cylinders, see Part 8.6.1.

8.5 Design of Storage Shed & Placement of Containers.

Storage safely requires appropriate design and approval from authorities. Many dimensions and criteria are prescribed in statute books, codes and standards. Some guidelines are also available from the supplier of materials. All such instructions are to be utilised from the design stage. Storage sheds should be constructed as per structural guidelines. Their safety and stability are important.

There are different designs of storage shades. Some are open from all sides while some are closed. Floor design, doors, windows and ventilators should consider properties of the materials to be stored. Floor slope on one side or at the centre, upper ventilation for low vapour density, lower ventilation for high vapour density, fire detectors at proper location, surrounding open space for easy movement, sufficient head room for fire fighting, proper stacking, racks and ladders to reach at height, proper lamps or tubes for sufficient lighting, proper air conditioning and maintenance of low temperature for storage of low boiling liquids, floor slope connected with drain and collection pit or retention basin, proper entry and exit ways, cross ventilation for comfortable temperature and dilution of air, sufficient roof height and proper roof design to maintain proper ventilation and temperature inside the shed and drain away raining water, alarm system in case of fire and leakages, proper locking system for explosives and poisonous chemicals, etc. are some of the factors which should be considered while designing a storage shed. Sufficient fire extinguishers should be kept nearby. Fire hydrant should be available near the periphery of the shed.

Placement of containers should be safe and with sufficient spacing in between and surrounding. Barrels of liquids should be kept on wooden support. Chlorine toners should be kept on rail or rollers so that they can be easily moved. Proper mechanical lifting devices should be provided. Bags and boxes should be stacked in such a way that they should not fall. .Gas detectors with alarms- should be provided to detect leaking gases. Gas cylinders should be stored at separate place and away from heat generating sources. Identification plates should be displayed properly.

8.6 Safe Storage and Handling of Chlorine, Ammonia, LPG, EO and Oleum

Safety aspects of storage and handling of some commonly used chemicals are stated below.

8.6.1 Handling and Storage of Chlorine

Properties of chlorine are : Greenish yellow gas, liquid or rhombic crystals, mp - 101 °C, bp - 34.5 °C, d 1.47 at 0°C (3.65 atm), vp 4800 mm at 20 °C, vd 2.49, TLV 1 pptn, STEL 3 ppm and TC_{L0} (human) 15 ppm. In addition to toxicity, it poses fire hazard when react with turpentine, ether, ammonia gas, hydrogen, powdered metals, polypropylene, wax, rubber, acetaldehyde, acetylene, alcohol and many materials. When heated, emits toxic fumes. When reacted with water or steam, produces toxic and corrosive fumes of HCI.

(A) Employee Selection and Training :

Persons affected with asthma, bronchitis chronic lung conditions, and irritations of the upper respiratory tract should not be employed where exposures to chlorine might occur. Training classes for both new and old employees should be conducted periodically to keep them conscious and informed of the hazards. They should be instructed and trained to adopt preventive measures in case of emergency and to use safety equipment.

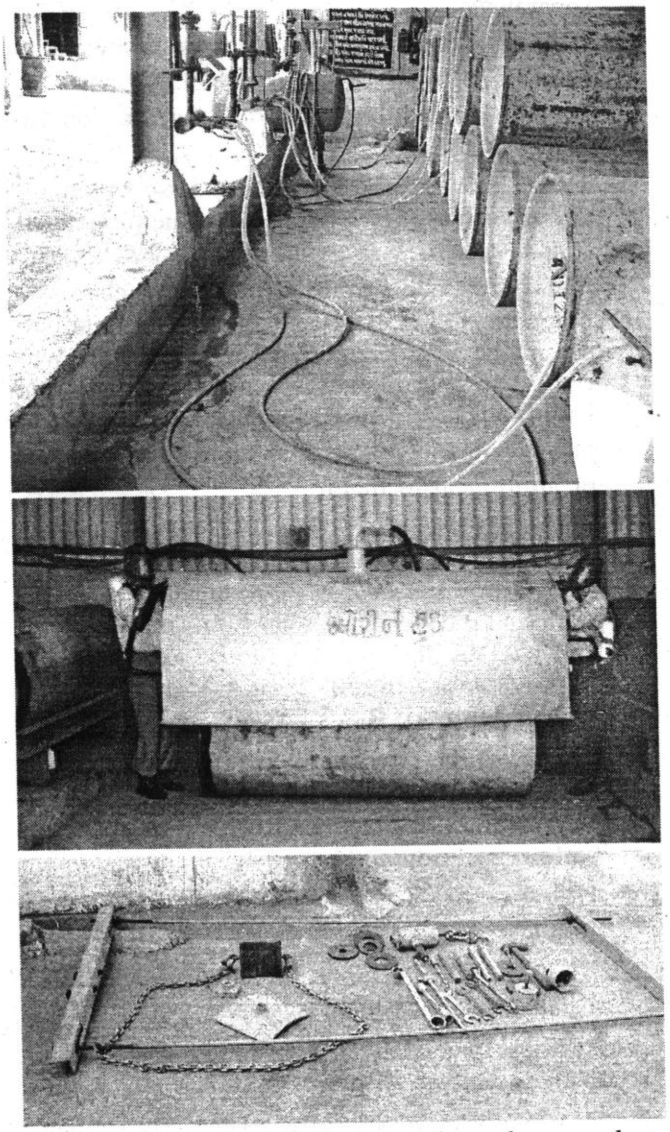
(B) Leakage tools:

1. Do not use water directing on leak.
2. Keep "emergency kits' handy and in proper working condition to control chlorine leakage and train workers in their use.
3. Appropriate facility for chlorine absorption through caustic soda/lime/soda ash solutions should be established and maintained in the event of leakage. The containers should not be immersed in same absorption media.
4. Ammonia water torches should be located at nearby places where chlorine containers are generally received, stored or used in process so as to facilitate easy detection of any leakage by white fumes.
5. Self-breathing apparatus, gas mask and 'emergency kits' should be located at strategic points under working condition and to be easily accessible in the event of emergency.

(C) Storage Area:

1. Storage area should be cool, dry, well ventilated, clean and protected from external heat source.
2. It should be remote from elevators, gangways or ventilating systems.
3. Ventilation must be sufficient to prevent accumulation of vapour pockets. All fan switches should be outside the storage area.
4. As far as possible, the building for the storage of chlorine should be entirely of non-combustible construction and separate from other building. In case the storage is not in a different building it should be ground floor with at least two exists opening outside and separated from other parts of the building by fire resisting walls and floors.

(D) Cylinders – Toners / Containers



1. Store chlorine cylinder up-right and secure them so that they cannot fall.
2. Ton containers should be stored on their sides on rails a few inches above the floor. They should not be stacked or racked more then one high.
3. Keep enough space between containers so that all are accessible in case of emergency.
4. Store the containers in a covered shed only. Keep them away from hot sun or any other source of heat.
5. Do not store chlorine container with explosives, acids, turpentine, ether, anhydrous ammonia, finely divided metals or other flammable material.
6. Cylinders should be stored on a cement floor sloping towards a pit capable of collecting all the liquid in the cylinders. Under no circumstances should water be allowed to run on to the chlorine in the pit.
7. Do not store containers in wet and muddy areas.
8. Use cylinders in order of their receipt.
9. Filled and empty cylinders should be stored separately.
10. Protective covers for valves should always be secured, even when the cylinders are empty.
11. No oil or any lubricant should be used on any valves of the containers.
12. The correct tool should be used for opening and closing valves, they should never be hammered

13. Cylinders should never be lifted by means of the metal cap, nor should rope slings, chains or magnetic device be used. The ton containers should be handled with a suitable cradle with chain slings combination with a hoist or crane having at least 2 metric tonnes capacity.
14. Never tamper with any fusible plugs of tonners or apply heat to them.

(E) Bulk Storage:

1. Being a compressed gas, all installations and tank vehicles used for storage and transport of liquid and gaseous chlorine have to be approved and licensed under the Static and Mobile Pressure Vessels (unfired) Rules 1981.
2. Appropriate minimum safety distances as stipulated in the above mentioned rules have to be maintained from buildings or group of buildings or adjacent property.
3. The tank has to be installed entirely above ground.
4. The bulk storage tanks for chlorine should be installed near waste-air system.
5. At least two safety valves should be connected to the waste-air system.
6. Pressure indicator with alarm should be available in the control room.
7. As an emergency measure, a perforated pipe, connected to the blower suction, around the storage tanks can be laid. In case of leakage the leaked chlorine will get sucked through this pipe which leads to waste-air system where it can be neutralised.
8. Safe bulk storage of chlorine call systematic inspection and maintenance.

(F) Handling Through Pipelines :

1. For piping dry chlorine, the material of construction generally used is carbon steel. Piping arrangements should as simple as possible.
2. The number of screws or flange joints should be kept to minimum.
3. Piping system should be well supported-and adequately sloped to allow drainage and low spot should be avoided.
4. Suitable allowance should be provided for pipe expansion due to changes in temperature.
5. Cleaning may be accomplished by pulling through each length of pipe a cloth saturated with trichloroethylene or other suitable chlorinated solvents.

(G) Emergency Measures:

1. In case of leakage or spillage, any person tackling of chlorine should be equipped with emergency kits, self breathing apparatus or masks and other appropriate items of personal protection.
2. In case of major leakage, all persons including neighbour (depending upon the situation) should be warned. Take the leaking cylinder to an isolated open place and roll it in such position so-that the leaking point is on the top. In such case only gas and not liquid will escape.
3. Approach from the windward side so that the escaping gas can be carried downwind to a lower level. In no circumstances should water or other liquid be directed towards leaking containers, so as to disperse the gas. Also the water solubility of chlorine is more at low temperatures, it will dissolve readily in the chilled water.
4. In case of large leaks, try to stop die flow of liquid by closing the valves.
5. After containing the liquids, one can use fluroprotein foam to prevent evaporation of the liquid.
6. In case of large leakage, the alternate solution is to absorb the chlorine in an alkaline medium such as caustic soda, soda or lime slurry. .

8.6.2 Handling and Storage of Ammonia

Properties of Ammonia are : Colourless gas, pungent odour, mp - 77.7 °C, bp - 33.35 °C, LEL 16%, UEL 25%, d 0.771 g/1 at 0 °C, vp 10 atm at 25.7 °C, vd 0.6, TLV 25 ppm, STEL 35 ppm, LC_{L0} (human) 10,000 ppm for 3 hrs, TC_{L0} (human) 20 ppm - irritant. Fire hazard low. Explosion hazard moderate when exposed to flame. When heated emits toxic fumes. To fight fire, stop flow of gas.

(A) General Preventive Measures

1. Designing of layout of area with due consideration of adequate natural or mechanical ventilation.
2. Use of properly selected material for construction of plant and equipment for handling of ammonia.
3. Preventive maintenance of all equipment in proper working condition.
4. Avoid contact of ammonia\ with certain other chemicals, including mercury, chlorine, iodine, bromine, calcium, silver oxide and hypochlorite.

(B) First Aid:

1. Keep trained first-aiders having the knowledge in the use of first aid equipment.
2. Provide necessary showers, eye-baths and oxygen administration apparatus.
3. Suitable notices should be fixed in convenient places regarding first aid measures.

(C) Personal Protective Equipment :

Provide adequate-and suitable personal protective equipment at all times e.g. gas-tight chemical goggles, self contained breathing apparatus, positive pressure hose masks, air line masks, chemical cartridge respirators, hard hats, soft-brimmed hats or caps, safety-toed rubber boots, rubber gloves, rubber apron or rubber coat, sleeves and trousers legs, etc.

(D) Leakage Tools:

1. Use large volumes of water directing on leak.
2. Leaks of a ammonia should be searched for, preferably with Hydrochloric acid solution or with a small cylinder of the compressed SO, gas. Because of the fire risk, sulphur candles should not be used.
3. Gas masks should be located at strategic points under working condition and to be easily accessible in the event of any emergency.

(E) Storage and Handling Controls :

Indoor Storage:
1. Storage should be cool, dry, well ventilated and protected from external heat sources.
2. The building protected with automatic sprinklers, vapour tight electrical equipment, good natural ventilation, good floor drainage and adequate exposition venting.

Outdoor storage:
The location should be away from any flammable liquid storage.

Bulk Storage:
1. In case of multiple storage facilities, a plan should be prepared for readily and definitely approaching all shutoff valves to be used for isolating various parts of the storage facilities.
2. Each storage area should be protected at least by one standard fire hydrant.

3. Gauge of glass should be provided with excess flow check valves. The Gauge glasses should not be longer than 120 cm and more than 60 cm between supports.
4. Storage tank construction should be of integrity and double wall type known as 'can in tank' type.
5. Each storage tank shall be equipped with two relief valves mounted on a 3-way hand valve to provide means for repair of faulty valve.
6. Install remote controlled valves at the bottom of ammonia storage tank.
7. Facilities for creating water curtains around the ammonia storage tanks should be created to absorb ammonia vapours if they leak .out, however, care should be taken not to add water to the liquid ammonia else it will worsen the situation.
8. Non refrigerated ammonia shall be stored in gas tight containers.
9. In the event of power failure, provision should be made to run the holding compressors of all the ammonia storage by emergency diesel generating sets so as to compress excess vapour into liquid ammonia (for refrigerated bulk storage system)
10. A flare stack should be provided to burr ammonia vapour in case safety valve fails to release ammonia pressure.

8.6.3 Handling and Storage of LPG

After Chlorine and Ammonia, the third chemical of major industrial use is LPG i.e. liquefied petroleum gas. As LPG, propane and butane are widely used as fuels. LNG, liquefied natural gas, is mainly methane. It is stored as liquid and transmitted by high pressure pipeline for industrial and domestic uses. NGL, natural gas liquids are mainly ethane, propane and butane. They are also transmitted by pipeline. Fire and explosion are the main hazards associated with them Boiling points and explosive limits of these hydrocarbons are as under :

Properties & Hazards of LPG :

No	Gas		BP oC	LEL %	UEL %
1	Propane	LPG & NGL	-42.1	2.3	9.5
2	Butane		-0.5	1.9	8.5
3	Methane	LNG	-161.5	5.3	15
4	Ethane	NGL	-88.6	3.0	12.5
2.05	Ethylene		-103.9	2.7	36
6	Propylene		-47.7	2.0	11.1

Commercial butane (n-butane) and propane are used as LPG. They exist as gases in ambient condition but can be liquefied under little pressure and on release of this pressure, they again become gases. As liquid its density is 0.5 and will float and vaporise on water surface. Therefore water is not good extinguishing media for LPG fire but it is essential to keep the vessel cool. Its vapour density is 1.5 and does not disperse easily. It tends to sink to the lowest possible level and if ignited in a confined space, it can explode also. Bottom ventilation (holes) near LPG cylinder allows leaking gas to go outside. Its explosive range is 2 to 10%. Its flame can travel back to the source giving flash back. It can cause cold burns to the skin due to its rapid vaporisation and lowering of temperature. Its very high concentration in air, is anaesthetic and on dilution, it becomes asphyxiant. It gives odour at l/ 5th of its LEL (i.e. at 0.4% of gas in air). Heavy leaks give hissing sounder icing in the area of leak. Small leaks may be detected by soap solution (bubbling). Never use a naked flame to detect it.

Its empty tank may still contain LPG vapour and if air enters in empty tank (due to any opening or leaking of valve) it can form an explosive mixture. Therefore it must be purged by inert gas first and gas-test should be made before doing any work on it.

Location & other Safety Aspects :

LPG tanks can be sited above or under ground. In any case the manhole and the safety valves should remain in open well ventilated position. Guidelines of Explosive Act & Rules, SMPV Rules, Petroleum Act & Rules and Controller of Explosives must be followed (See Part 3 of Chapter-28).

LPG vessels should not be located one above the other. The ground underneath should be concreted or compacted and free from pits, drains and culverts. Weeds, grass, shrubs, tress or any combustible material should be removed from the ground. Separation distances are mentioned in Table

Table 18.6 : Spacing of LPG Vessels

<table>
<tr><th colspan="2">Tank capacity in</th><th colspan="5">Separation Distances in mt</th></tr>
<tr><th rowspan="2">Tonnes</th><th rowspan="2">Litres x 1000</th><th colspan="3">Above Ground Vessels</th><th colspan="2">Under Ground Vessels</th></tr>
<tr><th>From surrounding or source of ignition</th><th>With fire wall</th><th>Between vessels</th><th>From surrounding or source of ignition</th><th>Between Vessels</th></tr>
<tr><td>0.05-0.25</td><td>0.15-0.5</td><td>2.5</td><td>0.3</td><td>1</td><td>0.3</td><td>0.3</td></tr>
<tr><td>0.25-1.1</td><td>0.5-2.5</td><td>3</td><td>1.5</td><td>1</td><td>1</td><td>1.5</td></tr>
<tr><td>1.1-4</td><td>2.5-9</td><td>7.5</td><td>4</td><td>1</td><td>3</td><td>1.5</td></tr>
<tr><td>4-60</td><td>9-135</td><td>15</td><td>7.5</td><td>1.5</td><td>3</td><td>1.5</td></tr>
<tr><td>60-150</td><td>135-337.5</td><td>22.5</td><td>11</td><td rowspan="2">0.25 x sum of dia of 2 adjacent vessels</td><td>3</td><td rowspan="2">Depending on site conditions</td></tr>
<tr><td>>150</td><td>>337.5</td><td>30</td><td>15</td><td>3</td></tr>
</table>

Slope should be given to the ground beneath the vessels, connections and equipment containing LPG to drive away any dripping or leakage towards a safe area. Such evaporation area or catchments pit should be at least 3 m from LPG vessels and have sufficient capacity to contain the largest credible leak and well ventilated to permit safe dispersion. Gas detectors should be provided in the pit to give warning of any LPG vapour.

For other details of fire walls, mechanical integrity, certification, marking, fittings (safety valves, drain connection, level gauges, valves, pumps and compressors), piping, vaporisers, security, fire precautions, loading and unloading facilities, commissioning and decommissioning, maintenance and examination, operational procedures and training see the reference no. 41 at the end.

Minimum safety distances are also given in IS:6044 (Part 2) for LPG storage and installations. Part I is for LPG cylinder installations.

8.6.4 Handling and Storage of EO

Properties of Ethylene oxide are : Colourless gas, mp - 111.3 °C, bp 10.7 °C, LEL 3%, UEL 100%, fp -17.8 °C, d 0.8711 at 20 °C, vp 1095 mm at 20 °C, vd 1.52, TLV I ppm, LD,, (rat)' 330 mg/kg, LC, (rat) 1462 ppm for 4 hrs. It is toxic, flammable and explosive. Fire & explosion hazard when exposed to heat or flame. To fight fire use CO_2, DCP or alcohol foam. It can react with acids and bases, alcohol, $AICI_2$, Al_2O, $FeCl_3$ Fe_2O_3, ammonia, copper, mercaptans, potassium, tin chlorides etc. Vaporises rapidly at ambient temperature, can cause cold burns and it is soluble in water.

PVC gloves, aprons, gum boots, goggles or face shield and breathing apparatus are necessary equipment to handle EO.

Safety Measures : Avoid heat, flame and ignition sources. Dilute spillage with plenty of water. Provide N, blanketing and preferably keep storage tank refrigerated. Its pressure should be kept within operating limits. Equipment cleaning may be done by citric acid. Prevent backflow of any chemical into the EO vessel.

Storage tank should be separated at least 15 mt from plants and buildings. Collusion of vehicles should be prevented by fencing and barricade. Spillage should be directed to a remote catchpit by an impermeable and sloppy floor.

It polymerises by iron rust, acids, bases and by chlorides of iron and other metals. Polymerisation is highly exothermic and may result in explosion.

Material of construction - stainless steel or MS aluminised from interior. Insulation - mineral wool covered by galvanised or SS cladding. Gaskets should be teflon coated.

Level gauges are float differential pressure type, torque tube type or magnetic float type. Compound pressure and vacuum gauge is preferable. Temperature gauge with high and low temperature alarm necessary. Double safety valves (at least one must be locked open) with 2 mt discharge outlet pipe, flame arrester on outlets and N_2 purging connections are required. Lines should not be of less than I inch diameter. To prevent reverse flow of EO, NRV and double block and bleed valve system is required.

In emergency, start water spray system or circulate chilled water through limpet coils or use fire water hydrant system. Knock down vapours with water spray and dilute continuously with water spray nozzle.

Pump temperature should not rise 3 °C. Therefore it should be kept cool by recycle from delivery to suction. A centrifugal pump with mechanical seal is normally used. If temperature margin (3 °C) increases, the pump should be stopped.

To avoid accident of EO road tankers, provide driver with TREMCARD, DCP extinguisher, PVC hand-gloves and respirators. In extreme case, EO may be transferred from one tanker (which cannot be pulled out or run) to another by using N_2 cylinders.

8.6.5 Handling and Storage of Oleum

Properties of Oleum are : It is a fuming heavy, yellow liquid (sulphuric acid) as H_2S0_4 + upto 80% $S0_3$. Mostly it comes in two categories : Oleum 23% i.e. in 100 kg, 23 kg SO_3, and 67 kg H_2SO_4 and Oleum 65% i.e. in 100 kg, 65 kg SO_3 and 35 kg H_2SO_4. It is highly irritant to skin, eyes and mucous membranes and via oral and inhalation routes. It can cause dangerous fire hazard by chemical reaction with reducing agents and carbohydrates. It can cause explosion also by chemical reaction with acetic acid, acetic anhydride, acetonitrile, acrolein, acrylic acid, aniline and many other chemicals. When heated to decompose, it emits highly toxic fumes of SO_2 (TLV 2 ppm and STEL 5 ppm). It reacts with water or steam to produce heat and toxic & corrosive fumes. TLV 1 mg/m^3

Dyke with slopped ground floor is required to contain storage tank(s). Acidproof lining in dyke -is necessary. Tank vent is to be connected with a sulphuric acid tank or scrubber with strong H_2SO_4 to prevent discharge of fuming SO_3. Ventline of oleum of more than 45% concentration needs steam tracing to prevent freezing of SO_3. A roof is required to protect from rain water. Nearby safety shower and eye washer is necessary for workers to dilute splashes or burns. To contain spillage ample quantity of sand or slaked lime or sodium carbonate should be kept aside. Water or wood dust should not be sprayed on leaking oleum. Self-breathing apparatus and acid-proof hand-gloves, aprons and gum boots are necessary. Level indicator and identification of content are also necessary. Remote control isolation valve at the bottom outlet or no bottom outlet and submersible pump on the top outlet are desirable.

Compressed air (free from oil, moisture and other impurities) is used to unload the tanker. The tanker outlet valve should be made of SS with teflon coating and leakproof. Air pressure data for a specific unloading rate is available from published literature.

DCP extinguishers are useful on small fires of oleum. Workers need training to attend emergencies due to oleum leakage.

9 PROCESS HAZARDS AND CONTROLS

9.1 Types of Processes and Operations

Generally in a chemical plant processes are classified as batch processes or continuous processes or their combination. In a batch process relatively more man-power is required, the workers are exposed to hazards more frequently and process automation and instrumentation are possible only to a limited extent. A continuous process is carried out in a closed vessel or circuit and good automation and instrumentation are possible. Many processes are operated at high pressure and high temperature (as incase of petroleum and petrochemical industry) for which automatic warning, monitoring and controlling devices are desired. Pressure and temperature should be properly controlled by cooling and safety devices. Flammable, explosives and solvent distillation processes should be carried out under inert atmosphere or vacuum and toxic processes should be connected with appropriate scrubbers and neutralisers.

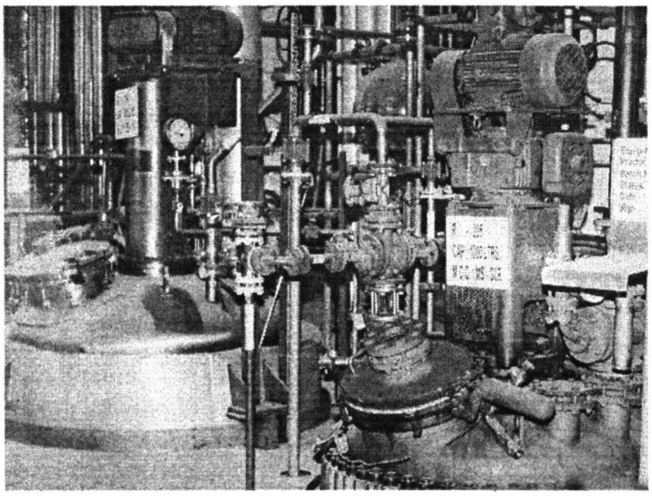
Study all unit processes arid unit operations with complete reaction documents i.e. all reaction data of intermittent behaviour as well as escaping behaviour out of the controlled parameters. This requires precise laboratory study and much details of side reactions, unwanted runaway reaction, generation of any flammable or toxic vapour, fumes, gas etc. or generation of abnormal pressure, temperature, expansion, contraction etc. at any stage of the process in control or out of control and adversely affecting the people or environment. Based on this, all necessary safety measures must be kept ready and provided to keep the reaction in control and to control again in the event of their going out of control also. Processes of exothermic and high pressure reaction, solvent distillation, distillation of toxic substance, polymerisation/chain reaction, , gas generation, filling etc., petroleum processing, autocatalytic reaction, decomposition, undesired reaction with other media, operating in or near explosive range, process of combustible material, process of toxic material , dust/ fume/gas process and process difficult to control need much attention.

Reaction Rate must also be controlled. The reaction rate is determined by the rates of the forward, reverse, and side reactions and by the rate of diffusion of the reactants. Intensity of heat supply, mass transfer coefficient, rate constant of a process, driving force of a process, pressure, temperature, catalysis, mixing or addition, stirring, time etc. are some important parameters to be controlled. Heat, material and energy balances must be understood properly. In practical terms 10 °C temperature rise may double the reaction rate. The reaction heat tends to accelerate the reaction and leads to runaway if cooling system is inadequate or fails suddenly. Many accidents have been noticed in such cases. Oxidation of hydrocarbons, nitration an polymerisation are some typical examples.

If quantity (mass) of chemical, its concentration or addition rate are changed (knowingly or unknowingly), violent or explosive reaction may take place. Therefore it is safer to keep quantity concentration and temperature as low as possible Reaction inhibitors and negative catalysts are used to reduce the activation energy.

The processes are also classified as unit processes and unit operations. They are explained below briefly :

9.1.1 Unit Processes



In such processes, by combination (chemical reaction) of two or more chemicals, a new product (compound) is formed. It indicates a chemical change.

Alcoholic caustic fusion : Reaction carried out a lower temperature (105-130^{0}C) using caustic soda o) potash and alcohol (like ethanol, methanol,, cellosolve, isobutanol).

Amination : Introduction of amino group in the molecule using liquid ammonia or any other aminating agent.

Caustic fusion : Reaction carried out in molten caustic potash/caustic soda at temperature above 150^{0}C.

Condensation : Reaction in which two or more molecules combine with the separation of water or simple substance.

Halogenation : Introduction of chlorine or bromine in the molecule using calcium hydroxide etc.

Hydroxylation : Introduction of hydroxyl group in the molecule using calcium hydroxide etc.

Nitration ; Introduction of nitro group in the molecule using nitric acid or mixed acid.

Oxidation : Introduction of oxygen or removal of hydrogen from the molecule using oxygen liberated by the action of acid and substance rich in oxygen.
